THE
AMERICAN CYCLOPÆDIA:

A

Popular Dictionary

OF

GENERAL KNOWLEDGE.

EDITED BY .

GEORGE RIPLEY AND CHARLES A. DANA.

VOLUME I.

A—A S H E R.

NEW YORK :
D. APPLETON AND COMPANY,
549 AND 551 BROADWAY.
LONDON : 16 LITTLE BRITAIN.
1873.

ENTERED, according to Act of Congress, in the year 1857, by D. APPLETON AND COMPANY, in the
Clerk's Office of the District Court of the United States for the Southern District of New York.

ENTERED, according to Act of Congress, in the year 1873, by D. APPLETON AND COMPANY, in
the Office of the Librarian of Congress, at Washington.

23

P R E F A C E .

THE work originally published under the title of THE NEW AMERICAN CYCLOPEDIA was completed in 1863, since which time the wide circulation which it has attained in all parts of the United States, and the signal developments which have taken place in every branch of science, literature, and art, have induced the editors and publishers to submit it to an exact and thorough revision, and to issue a new edition entitled THE AMERICAN CYCLOPEDIA.

Within the last ten years the progress of discovery in every department of knowledge has made a new work of reference an imperative want. The physical sciences have revealed unexpected and important relations in the material world. Chemistry and physiology have been well nigh reconstructed. Light, heat, and force are now subjected to new processes of study, with results truly astonishing. The elements of matter have undergone a fresh analysis, and are arranged in new classifications; the spectroscope has made known the intimate composition of the stars, and opened the secular history of the sun; while the researches of the physiologist and the microscopist have won brilliant victories in the field of animated nature. No less remarkable advances have been made in ethnology, archæology, and history. The records of antiquity have received a new interpretation, and a wonderful light has been thrown upon the annals of our race.

The movement of political affairs has kept pace with the discoveries of science, and their fruitful application to the industrial and useful arts and the convenience and refinement of social life. Great wars and consequent revolutions have occurred, involving national changes of peculiar moment. The civil war of our own country, which was at its height when our last volume appeared, has happily been ended, and a new course of commercial and industrial activity has been commenced. The second French empire has perished, and the third French republic has been proclaimed amid the perturbations of one of the greatest conflicts described in history. A new German empire has been created by the same mighty convulsion; the Spanish monarchy has fallen, and a republic for the first time has been founded on Spanish soil. Austria, defeated by Prussia, has been reconstructed on a new basis. Italy has been united in one kingdom, with Rome for its capital, and the temporal power of the Pope completely overthrown. Japan has experienced one of the most remarkable of revolutions, and significant changes have occurred in China and in other parts of Asia. Large accessions to our geographical knowledge have been made

by the indefatigable explorers of Africa, and a new impulse has been given to human activity on that continent by the discovery of gold and diamonds.

The great political revolutions of the last decade, with the natural result of the lapse of time, have brought into public view a multitude of new men, whose names are in every one's mouth, and of whose lives every one is curious to know the particulars. Great battles have been fought and important sieges maintained, of which the details are as yet preserved only in the newspapers or in the transient publications of the day, but which ought now to take their place in permanent and authentic history. Since the completion of our first edition, the decennial censuses of the United States and of Great Britain have been taken, as well as many other censuses throughout the world, and the statistics of population, commerce, manufactures, and other branches of industry, that were correct at that time, have been superseded by new material.

In preparing the present edition for the press, it has accordingly been the aim of the editors to bring down the information to the latest possible dates, and to furnish an accurate account of the most recent discoveries in science, of every fresh production in literature, and of the newest inventions in the practical arts, as well as to give a succinct and original record of the progress of political and historical events.

The work has been begun after long and careful preliminary labor, and with the most ample resources for carrying it on to a successful termination. Several of the most experienced and competent of the writers of the original work have been employed as revisers, and the assistance of new contributors of eminent distinction in their respective departments has been secured, in addition to that of members of the former corps. Only such portions of the original matter have been retained as were found to be in accordance with the existing state of knowledge; every statement has been compared with the latest authorities; every error that could be discovered by the most careful scrutiny has been corrected; many emendations in arrangement and style have been introduced; all apparent superfluities in subject and treatment have been retrenched; a multiplicity of new titles, most of which have sprung up since the issue of the first edition, have been added; while those which have become obsolete, or which were found to have lost most of their former importance, have been made to give place to others of fresher interest and unquestionable value. None of the original stereotype plates have been used, but every page has been printed on new type, forming in fact a new Cyclopædia, with the same plan and compass as its predecessor, but with a far greater pecuniary expenditure, and with such improvements in its composition as have been suggested by longer experience and enlarged knowledge.

The illustrations which are introduced for the first time in the present edition have been added not for the sake of pictorial effect, but to give greater lucidity and force to the explanations in the text. They embrace all branches of science and of natural history, and depict the most famous and remarkable features of scenery, architecture, and art, as well as the various processes of mechanics and manufactures. Although intended for instruction rather than

embellishment, no pains have been spared to insure their artistic excellence; the cost of their execution is enormous, and it is believed they will find a welcome reception as an admirable feature of the Cyclopædia, and worthy of its high character.

The design of THE AMERICAN CYCLOPEDIA, then, as it was that of the original work on which it is founded, is to furnish a condensed exhibition of the present state of human knowledge on the most important subjects of inquiry. The discussion of the controverted points of science, philosophy, religion, or politics does not enter within its plan; but it aims exclusively at an accurate and impartial account of the development of opinion in the exercise of thought, of the results of investigation in every department of science, of the prominent events in the history of the world, of the most significant productions of literature and art, and of the celebrated individuals whose names are associated with the phenomena of their age.

In preparing the materials of the work, neither the editors nor their collaborators have attempted to make it a vehicle for the expression of personal notions. As far as was consistent with the nature of the case, they have confined themselves to the historical relation of facts, without assuming the function of advocates or judges. In instances which seemed to demand a positive verdict, they have endeavored to present an illustration of evidence rather than an exhibition of argument. Each subject has been treated in the point of view of those with whom it is a specialty, and not in that of indifferent or hostile observers. In order to secure the most complete justice in this respect, the various articles in the work have been intrusted, as far as possible, to writers whose studies, position, opinions, and tastes were a guarantee of their thorough information, and furnished a presumption of their fairness and impartiality.

In a work primarily intended for popular instruction and entertainment, it is obvious that elaborate treatises on the subjects which are brought forward in its pages would be inappropriate. Hence no attempt has been made to furnish the masters of literature and science with new facts or principles in their peculiar branches of study. On the contrary, the editors have only sought to present such selections from the universal treasury of knowledge as will place the cultivators of one department of research in possession of the achievements of other departments, and especially to spread before the great mass of intelligent readers a faithful report of the opinions, systems, discoveries, events, actions, and characters that make up the history of the world.

A popular method, however, has not been pursued at the expense of thoroughness of research and copiousness of statement in regard to topics which seemed to demand a more extended treatment. Ample space has been allotted to articles of this character, especially on subjects connected with modern scientific discoveries, mechanical and industrial inventions, the principles of physiology and hygiene, and American and European history, biography, and geography. Several of our titles in those divisions are treated with a fullness of detail, and present a variety as well as an exactness of information, which it is believed will entitle them to the rank of standard authorities.

While the brevity that has been observed on points of secondary interest has enabled the editors to give a greater number of titles than is usual in productions of similar intent, they have rigidly excluded those which would increase the size of the work without enhancing its value. The terms which require only the common dictionary definitions, and the proper names which fill an unimportant place in gazetteers and biographical dictionaries, have been rejected on system.

The materials which have served as a foundation for the work have been derived from a great variety of sources. Besides the standard works on special subjects, scientific, literary, or historical, the numerous encyclopædias, dictionaries of the various branches of study, and popular conversations-lexicons, in which the literature of the last quarter of a century is so singularly rich, have been diligently consulted and compared. Their contributions to the common stock of knowledge have furnished many valuable facts, statements, and suggestions; while recent biographies, histories, books of travel, scientific treatises, statistical reports, and the current journals and periodical literature of the day have been put in constant requisition, and their contents carefully digested and utilized.

A great mass of important information has been derived from consultation with practical men in different branches of manufactures and other industrial processes: public officials have liberally supplied us with data from their archives; the representatives of science have imparted to us the results of their experience; the constructors of great works of internal improvement now in progress have favored us with the explanation of their methods and plans; the journalists throughout the country have promptly responded to our request for facts in their respective localities; while many of the writers employed upon the work have enriched it with the fruit of their personal researches, observations, and discoveries in the branches of learning in which their names have attained an honorable distinction.

The editors of this Cyclopædia are unwilling that the first volume of the new edition should pass from their hands without a distinct expression of their obligations to their staff of revisers, to their corps of regular contributors, and to the numerous men of eminence in science, literature, and official position, whose effective coöperation has lightened their own labors, and laid the foundation for the utility and value of the publication.

The volume now presented to the public may be regarded as an earnest of the literary and typographical execution of the whole work. It will be completed mainly by the same writers whose contributions are contained in the first edition, together with many others of equal ability (whose names will be hereafter announced), and will be made to pass through the press as rapidly as is consistent with mechanical accuracy.

THE AMERICAN CYCLOPÆDIA.

A

AALBORG

A, THE first of the vowels, and the first letter of all written alphabets except the Amharic or Abyssinian, of which it is the thirteenth, and the Runic, of which it is the tenth. This almost universal precedence appears to be due to the fact that its typical and probably only original sound (*ah*) is the most easily uttered of all sounds, being produced by a simple expulsion of the breath through the freely opened throat and mouth. In English, A has at least four distinct sounds, as heard in *mate, mat, mart, ball*; and that heard in *mare* is usually reckoned a fifth. In the words *any, many*, it has exceptionally the sound of short *e*. In combination with other vowels, it is sometimes heard alone, as in *maid, aunt, pear*; and is sometimes silent, as in *boat, head, beauty*. The historical features of A are interesting. Its sound (probably that which we now have in *mart*) was disliked by Cicero, and in the treatise *De Oratore*, c. xlix., he terms it *insuavissima littera*. By the ancients, A was employed as a numeral, and stood for 500, and when a dash was placed over it, thus, \bar{A} , for ten times that number, or 5,000. It is the first of the seven Dominical letters in the Julian calendar—an imitation of the *litteræ nundinales*, which were in use among the Romans long before the introduction of Christianity. In logic, the letter A denotes a universal affirmative. In the *comitia* of the Romans, it was used in giving suffrages. In criminal trials it represented *Absolvo*, I acquit; hence Cicero, in his speech for Milo, terms it *littera salutaris*. In ancient inscriptions, A stands for *Augustus, Augustalis, ager, agit, aivnt, aliquando, antique, assolet, aut*; $\Delta\Delta$ for *Augusti, Augustæ, Aulus Agerius, æs alienum, ante audita, apud agrum, aurum argentum*; $\Delta\Delta\Delta$ for *Augusti* when three in number, and for *aurum, argentum, æs*. On the reverse of ancient medals, it indicates the city in which they were issued, as Argos or Athens; on modern coins it is the mark of the city of Paris, doubtless taken anagrammatically from

the last letter of the name *Lutetia*. A is also a frequent abbreviation, as in A. D. for *Anno Domini*, A. M. for *Artium Magister* or *Anno Mundi*, &c. In medical prescriptions it is used thus, \bar{a} , or \bar{aa} , for *ana*, of each. In bills of exchange it is in England and France an abbreviation for *accepted*. *AAA* is the chemical abbreviation for *amalgama*.—A, in music, is the nominal of the sixth diatonic interval of the first octave of the modern scale. It corresponds to the *La* of Guido. A was the lowest note of the ancient Greek scale, and for many centuries represented the deepest tone used in music. Alterations in the scale were made, however, in the 10th century by Guido, and subsequently by others, so that at present C is the first note of the natural scale, and A the sixth diatonic interval; *a* marks the same interval in the second octave. A is also the nominal of one of the two natural modes.

AA, the name of a number of small rivers in central and northern Europe, derived from the Celtic *ach*, or Teutonic *aa*, flowing water. The most important are: **I.** A river of the Netherlands, province of North Brabant, which joins the Dommel at Bois-le-Duc. **II.** A river of Russia, government of Livonia, flowing into the gulf of Riga. **III.** A river of France, department of Le Nord, flowing into the North sea near Gravelines. **IV.** A river of Switzerland, canton of Aargau, which forms the lakes of Baldegg and Hallwyl, and flows into the Aar. **V.** A river of Switzerland, canton of Unterwalden, which flows through the lake of Sarnen, and empties into the lake of Lucerne.

AACHEN. See AIX-LA-CHAPELLE.

AALBORG (Eel Town), a seaport and city of Denmark, in Jutland, capital of a district of the same name, on the S. shore of the Lymfjord, 15 m. from its outlet in the Cattegat; pop. in 1870, 11,721. It has a school of navigation, manufactories, and a large herring fishery. It was a celebrated seaport as early as 1070, and for a long time the most important mart of Jutland for all native products.

AALEN, a town of Württemberg, capital of a bailiwick in the circle of Jaxt, on the Kocher, 45 m. E. N. E. of Stuttgart; pop. in 1871, 5,552. It has woollen factories, tanneries, and several iron works.

AALI PASHA, a Turkish statesman, born in Constantinople in 1815, died there, Sept. 7, 1871. The son of a priest and a functionary, he entered the public service at an early age as a protégé of Reshid Pasha. From 1834 to 1836 he officiated as secretary of legation in Vienna, and previous to his return to Turkey visited Russia. In 1838 he was attached to the legation at London, and subsequently became chargé d'affaires. He was under-secretary of foreign affairs in 1840, and ambassador to England from 1841 to 1844. After his return from England he was a member of the supreme council of state and of justice, foreign minister, and chancellor of the imperial divan. Under the administration of Reshid Pasha he continued to be minister of foreign affairs from 1846 to 1852. His ability in settling the controversy with Greece caused his promotion to the rank of mushir (field marshal) and pasha. Toward the end of 1852 he was for a short time grand vizier or prime minister; but disagreeing with his associates in the cabinet on important questions, and being held in a measure responsible for the failure of the first Turkish loan, he retired, and was appointed governor general of Smyrna (1853), and afterward of Brusa (1854). Toward the end of 1854, however, during the Crimean war, he was restored to power as president of the newly established board of reforms (*Tanzimat*), and as minister of foreign affairs. In 1855 he attended the conference of Vienna, and while absent was appointed grand vizier. He took a leading part in the convention which framed the Hatti-Ilumayum of Feb. 18, 1856, confirming all the guarantees previously given to the Christian powers for the equal rights and religious liberty of Christians in Turkey. As minister plenipotentiary he signed in 1856 the treaty of Paris, though he did not fully approve of its terms. Indeed, he found so many difficulties in regard to the arrangements of that treaty for the settlement of the Roumanian question that he relinquished his post of grand vizier to Reshid Pasha, Nov. 1, 1856, but the sultan induced him to remain a member of the cabinet without portfolio, and an active member of the supreme council. On Reshid Pasha's death he resumed the office of grand vizier, Jan. 11, 1858, but retired again in 1859, on account of dissatisfaction with the demands of the foreign powers and the reformatory measures of Abdul-Medjid. But he subsequently returned to his old post in the Tanzimat, and acted as grand vizier during the temporary absence of Rushdi Pasha, and as minister of foreign affairs during Fuad Pasha's visit to Syria, on occasion of the massacres of Damascus. After the accession of the present sultan, Aali Pasha was once more

called to the head of the cabinet as grand vizier, June 7, 1861, but in November yielded that post to Fuad Pasha, becoming again minister of foreign affairs. In 1864 he attended the conference at Paris to settle the Roumanian question, and continued to preside over foreign relations till 1867, when he once more exchanged offices with Fuad. In June, 1867, the sultan appointed him regent of the empire during his visit to European courts. In September he went to Crete to finish the insurrection in that island, which however continued till 1868; but it was due chiefly to his moderation that a war with Greece was then avoided. After the death of Fuad Pasha (Feb. 11, 1869) Aali discharged the duties both of minister of foreign affairs and grand vizier. In the recent complications with Egypt, as well as in the precarious relations with Roumania, Albania, Bulgaria, Servia, and Montenegro, he displayed his characteristic moderation, and prevented an outbreak, while preserving the integrity of the Ottoman empire. In the London conference of 1870 for the consideration of the Russian demand for the denaturalization of the Black sea, and the modification to that effect of the treaty of Paris of 1856, he bore a conspicuous part, insuring the safety of Turkey. Before he died he had restored good relations with Russia and Greece, and checked the ambition of the khedive. His interest in reforms made him unpopular with the Turks of the old school, though with all his appreciation of Christian civilization he never ceased to be a zealous Moslem. He was small in stature, unseemly in appearance, diffident in manner, and distinguished for official honesty. His biographer, Fatin Effendi, ascribes to him poetical talent.

AALEST. See **ÆLEST**.

AALESTEN, a town of the Netherlands, province of Gelderland, district of Zutphen, situated on the Aa; pop. in 1867, 6,160, and increasing rapidly. It has many tanneries and factories.

AARAU, or **Aare**, the largest river of Switzerland after the Rhine and the Rhône. It rises in the glaciers of the Grimsel in the Bernese mountains, forms at Handeck a magnificent waterfall above 290 feet high, flows N. W., N. E., and N. about 120 miles through the lakes of Brienz and Thun, and through the cantons of Bern, Soleure, and Aargau, and falls into the Rhine between the village of Coblenz, in Aargau, and Waldshut, in Baden. Its chief affluents are the Saane, Thiele, Emmen, Wigger, Reuss, and Limmat.—Aar is also the name of several small rivers in Germany.

AARAU, a town of Switzerland, capital of the canton of Aargau, on the Aar; pop. in 1870, 5,449. The town is well built, and is celebrated for its manufactories of mathematical instruments. In August, 1712, a peace was concluded at Aarau between the cantons of Bern and Unterwalden. During the time of the Helvetic republic (1798) Aarau was the seat of the central government.

AARD-VARK (*orycteropus capensis*), a plantigrade animal of the class *mammalia*, order *edentata*, peculiar to Africa, and extremely common in the southern part of that continent, especially in the Cape Colony, where it is called *aard-vark* or earth pig. It was formerly classed with the *myrmecophaga*, or ant-

eaters. The aard-vark is more closely allied in anatomical structure and in its dental system to the armadillos than to any other class of animals, although it has not their defensive armor. It has neither incisors nor canine teeth, and its molars are different in structure from those of any other quadruped; they have no roots, and, like the tusks of the elephant and the incisors of the gnawing animals, are constantly increased by the deposit of new bony matter at the base to compensate for the continual wear at the extremity. It has large, flat feet, hollow on the under side, with powerful claws, the toes, four in front and five behind, gradually diminishing outward from the interior and second, corresponding to the fore and index fingers of the human hand. This structure gives it great facilities for digging the burrows in which it lives, and for excavating the hills of the great ants, on which it feeds exclusively, as do the *pangolins* of Asia, the *myrmecophaga* of America, and the *echidna* of Australia. At first sight, the aard-vark resembles a small, short-legged pig. Its length, when full-grown, exclusive of the tail, is about 3 feet 5 inches, its head 11 inches, its ears 6 inches, and its tail 1 foot 9 inches. Its head is long and attenuated, its upper jaw projecting beyond the lower; its mouth small; its tongue long, slender, and flat, unlike the cylindrical organ of the *myrmecophaga*, nor capable of so great protrusion, but, like theirs, covered with glutinous saliva, which firmly retains the ants with which it comes in contact. Its ears are long, erect, and pointed; its eyes of moderate size, two thirds nearer to the brow than to the snout. Its body is thick and corpulent, the limbs short and very strong. The skin is generally bare, but thinly scattered with a few stiff, reddish-brown hairs, which are more numerous on the hips and thighs than on the other parts of the body. The tail is nearly naked, very thick at the base, but tapering to a sharp point at the end. The aard-vark is a very timid, inoffensive animal, burrowing in the ground, if pursued, so rapidly as to get

wholly out of sight in the space of a few minutes, and working inward with such power and quickness that it is impracticable to dig him out. It is nocturnal in its habits and in its hours of feeding, and becomes exceedingly fat. Its flesh is wholesome, and its hams, salted and dried, are good eating.

AARD-WOLF (earth wolf; *proteles Lalandii*, *viverra cristata*), a singular quadruped, of the digitigrade carnivorous mammalia, first brought from Caffraria by the traveller Delalande. To the external appearance and osteological structure of the hyena it unites the head and feet of the fox, and the intestines of the civet. It has five toes on the fore feet, the interior one of which is situated high above the others, and does not touch the ground, and but four behind. Its fore legs are much longer than the hind ones, which makes it comparatively slow in its motions. In size it is about equal to a full-grown fox, which it also resembles in its pointed muzzle; but it stands much higher on its legs, while its ears are larger and more naked, and its tail shorter and not so bushy. It has a coarse, stiff mane, which runs along the whole of its neck and back, and is erectile when the animal is enraged. Its general color is pale ash, with a slight tinge of yellowish brown; the muzzle is black, and nearly naked, with the exception of a few stiff moustaches. Around its eyes, and on each side of the neck, are dark brown transverse marks, and on the body are eight or ten simi-

lar bands, the arms and thighs being barred with the same color. Its legs and feet are dark brown behind, and gray on the inner surface. The long hairs of the mane are gray, with two bands of black, the latter occupying the tips; those of the tail, which are equally stiff, are of the same color. The ears are brown without, and gray internally. In habits it resembles the fox, constructing burrows, in which it sleeps during the day, going abroad and feeding only by night. It is timid, inoffensive, and sly in its habits, but many individuals are ordinarily found residents of the same burrow, which has always several apertures for escape. It is said to run very fast, in spite of the excessive length of its fore legs.

AARGAU (Fr. *Argovie*), a Swiss canton, bounded by Zürich, Zug, Lucerne, Bern, Soleure, Basel, and the Rhine, which separates it from Baden; area, 542 sq. m.; pop. in 1870, 198,873,

of whom 107,703 were Protestants, 89,180 Roman Catholics, and 1,542 Jews. The country is diversified by hills, mountains, and valleys, the soil well cultivated, and extensive vineyards abound. It is watered by the rivers Aar, Reuss, and Limmat, the two latter being navigable. Cottons, silks, and linens, woven by hand, are the principal manufactures, and, with straw hats, cheese, corn, wine, and cattle, form the chief exports. The canton is divided into the following eleven districts: Aarau (pop. 19,247), Baden (23,462), Bremgarten (18,751), Brugg (17,162), Kulm (20,790), Laufenburg (14,407), Lensburg (18,497), Muri (14,297), Rheinfelden (11,417), Zofingen (26,986), and Zurzach (13,861). Capital, Aarau. The canton was organized in 1803. Each of the 50 electoral districts elects a member of the grand council for every 260 voters and for a fraction of over 130; state officers and teachers of state schools are ineligible. The grand council elects from its number a governing council (*Regierungsrath*) of eleven members, three of whom at least must be Protestants and three Catholics.—On Feb. 13, 1841, all the convents of the canton were abolished and their property confiscated. The protest of several Catholic cantons against this measure was so vigorously supported by the Austrian government, that the government of the canton in 1843 re-established four female convents. Most of the cantons were satisfied with this, but the minority were induced by it to organize the Sonderbund. In 1862 the grand council declared in favor of the emancipation of the Jews, but the people voted it down.

AARHUUS, a seaport of Denmark, in East Jutland, capital of Aarhus bailiwick, on the Cattegat, 37 m. S. E. of Viborg; pop. in 1870, 15,925. It contains one of the finest and largest cathedrals in Denmark, a library, and a museum. Its commerce is considerable, and it has a regular steam communication with Copenhagen.

AARON. I. Son of Amram, of the tribe of Levi, elder brother of Moses, his spokesman in the embassy to the court of Pharaoh, and subsequently the first high priest. He was recreant to his trust in the absence of Moses upon Mount Sinai, and made the golden calf for the people to worship. He died on Mount Hor at the age of 123 years, and his office descended to Eleazar, his son. II. A physician of Alexandria, Egypt, who flourished in the 7th century. He wrote on medicines, and is the first author who mentions the small-pox.

AARSENS, *Frans van*, a Dutch diplomatist, born at the Hague in 1572, died in 1641. In 1599 he was appointed ambassador at the French court, and concluded (1609) the truce of 12 years between the United Provinces and Spain. He was afterward ambassador to Venice, and sent on numerous special missions, and in 1640 went to England to negotiate the marriage between William prince of Orange and the princess Mary. He was originally a pro-

tégé and partisan of Barneveldt, but turned against him and was the chief instrument in his destruction.

AASEN, *Ivar Andreas*, a Norwegian philologist, born at Oersten, Aug. 5, 1813. The son of a poor farmer, he became well educated through his own efforts. He first devoted himself to botany, and then studied the different local dialects of his country, producing *Det norske Folkesprogs Grammatik* (Christiania, 1848) and *Ordbog over det norske Folkesprog* (1859). Among his more recent works is one on Norwegian proverbs (1856). An annuity has been conferred upon him by Norway.

AASVÅR, a group of small islands, below the arctic polar circle, about 12 m. from the Norwegian coast, forming part of the prefecture of Nordre Helgoland and of the parish of Donnaes, in the province of Nordland. They have recently acquired importance as a station for herring fisheries, giving employment to over 10,000 fishermen. The annual value of the exports is estimated at about \$1,000,000, and the fish is known as the great Nordland herring. They are caught from December to January, and sometimes in quantities exceeding 200,000 tons. During the rest of the year the islands are almost deserted.

AB, the eleventh month of the Jewish civil year and the fifth of the ecclesiastical, corresponding to a part of July and a part of August. The ninth of the month is one of the principal Jewish fast days, commemorating both the destruction of the temple of Jerusalem by Nebuchadnezzar and that by Titus.

ABABDEH, or *Ababbie*, tribes of N. E. Africa, tributary to Egypt, under the jurisdiction of a resident sheik, spread over the N. part of the desert between the Nile and the Red Sea, from Kenneh to Asswan and Dera, and, according to Belzoni, as far as Suez. They are divided into three principal tribes—the Fokara, Ashabat, and Melaykab—and number about 120,000. Their armed force consists of about 20,000 men. They are often erroneously confounded with the Bedouin Arabs, but differ from them in appearance, habits, and language. Some of them are agriculturists, but they lead generally a nomadic life, and act as guides to the Sennaar caravans, which start from Daraweh, 40 m. N. of Asswan. They have few horses, but many camels and dromedaries, the latter being especially celebrated in the East. They fight mounted on camels, naked to the waist. Burckhardt, in his "Travels in Nubia," regards them as of Arab stock, but is not supported in this view by other authorities. However, they have intermarried with Arabs, and adopted their religion. To the Romans they are believed to have been known under the name of Blemyses; but after the Arab conquest of Egypt they appear under the collective name of Bega, as traders on the Red sea. Nearly on a line with Asswan, in the Ababdeh territory, are the ruins of Berenice.

ABACO, *Great*, a long and crooked island, the

largest of the Bahama group, 150 m. E. of Florida, 80 m. long by an average of 15 wide. Its N. point is in lat. 26° 30' N., lon. 76° 57' W. Pop. about 2,000, including Little Abaco, adjoining, 28 by 4 to 5 m. Many of the inhabitants are white creoles. They work at ship-building, turtling, and wrecking.

ABACUS. I. In architecture, the upper part of the capital of a column, supporting the en-

Corinthian Abacus.

Doric Abacus.

tablature, said to have been designed from a square tile laid over a basket. The shape of the abacus differs in different orders. II. Among the ancients, a cupboard. III. The mystic staff carried by the grand master of the Templars. Its head was of silver, marked with the peculiar cross of the order; but it was supposed to bear another secret device, concealed or disguised, and revealed only to the initiated, being no other than the orthophallic symbol of heathen antiquity, indicating the worship of the generative power as distinct from the creative attribute of God. IV. A calculating machine to facilitate arithmetical computations. In China it

Counting Abacus.

is much employed. The Chinese call it shwanpan. A man who uses the shwanpan can tell the amount of a column of figures the moment they are read off to him. It is also found in Russian shops and counting houses. Improved forms of this machine are known in the United States as the "adder."

ABAD I. (ABU AMR UBN HABED), first Moorish king of Seville, and founder of the Abadite dynasty, born in the latter half of the 10th century, died about 1041. His ancestors, from Emesa in Syria, had settled at Tocina, on the Guadalquivir. He was brought up at Seville, where by his munificence and amiability he became so popular that the people, wearied by the bad administration of the Ommyyad rulers, chose him in 1015 as their king. After consolidating his power at Seville, he added Cordova to his dominions, and reigned 26 years.—**Abad II.** (MOHAMMED IBN HABED), son of the preceding, born in 1012, died in 1069. He added the territory of Carmona to Seville, gradually acquired all Andalusia, and aimed at the subjugation of entire Spain. He was cruel and relentless.—**Abad III.** (MOHAMMED IBN HABED), son of the preceding, born in 1039, died in 1095. He was celebrated for love of art and letters and for poetical talent. He continued the conquests of his father and grandfather, added a part of Portugal to his dominions, and threatened Castile. At the same time he was tolerant and kindly. Alfonso VI. of Castile, after having been his enemy, married his daughter. This

alliance with a Christian king excited the jealousy of the petty Moorish rulers. Aided by the king of Morocco, they attacked Alfonso and Abad, and the latter only avoided the sacking of Seville by surrendering (1091). He was imprisoned four years in Morocco, where his four daughters were compelled to spin wool for their subsistence. His poems, composed during his captivity, were admired. The Abadite dynasty ended with him.

ABADDON. See **APOLLYON.**

ABAKA KHAN, second Mongol king of Persia, of the family of Genghis Khan, succeeded his father, Hulaku Khan, in 1265, and died about 1280. He completed the conquests of his father, restored Bagdad, and consolidated the Mongol sway over western Asia.

ABANA, mentioned in Scripture in connection with Pharpar as a river of Damascus, is now generally identified with the Barada, the Chrysorrhoeas of the Greeks, while the Awaj is considered identical with Pharpar.

ABANCOURT, Charles Xavier Joseph d', minister of Louis XVI. of France, born at Douay, July 4, 1758, died Sept. 10, 1792. At the commencement of the revolution he was captain in the cavalry, but was made minister of war in consequence of the occurrences of June 20, 1792. During the proceedings of the 10th of August he was accused of being a foe to freedom, and was imprisoned. With many others he was dragged before the tribunal at Orleans, whence he was to be reconducted to Paris; but the transport was mobbed on the way at Versailles, and Abancourt and his fellow prisoners were butchered.

ABANO, Pietro d' (Lat. *Petrus de Apono*), an Italian philosopher, born at Abano in 1250, died in 1316. He studied at Constantinople and Paris, became professor of medicine at Padua, and wrote several works on philosophy and medicine. Like other men of his age, he practised astrology, and was accused of magic and sentenced to be burnt, but died in prison.

ABARBANEL. See **ABRAVANEL.**

ABARCA, Joaquin, a Spanish bishop, born in Aragon about 1780, died at Lanza, near Turin, June 21, 1844. Having been promoted in 1823 from a village priest to be bishop of Leon, for supporting the absolute rule of Ferdinand VII., he accompanied the pretender Don Carlos to Portugal and England, and acted as his agent, and in 1836 as his prime minister in the Basque provinces, but finally forfeited his regard. Being banished from Spain after various political intrigues and adventures, he retired in 1839 to a monastery at Lanza, where he remained until his death.

ABARIM, a mountain or range of highlands in eastern Palestine, facing Jericho. Its most elevated spot was Nebo, on which Moses died.

ABASCAL, José Fernando, a Spanish statesman, born at Oviedo in 1743, died in Madrid, June 13, 1821. He entered the Spanish army in 1762, and distinguished himself as colonel in the war against the French republic. In 1796

he became governor of Cuba, and defended Havana against the British. Thence transferred to be governor of New Galicia, he was in 1804 appointed viceroy of Peru. On his journey thither he was captured by the English, but escaped and reached Lima. His administration was successful, and for some time he checked the movement for independence in Peru, the Plata states, and Chili. On returning home, in 1816, he was greeted as a national benefactor and made a marquis.

ABAUZIT, Firmin, a French theologian and antiquary, born at Uzès, Nov. 11, 1679, died in Geneva, March 20, 1767. The revocation of the edict of Nantes banished his mother to Geneva while he was yet a boy, and her devotion to the reformed church incited the young Firmin to study theology and the exact sciences. At the age of 19, while travelling in Holland, he won the friendship of Bayle and Basnage. In England he became the friend of Newton, and was distinguished by William III. Voltaire and Rousseau spoke highly of his genius and wisdom. His writings include "An Essay on the Apocalypse," "Reflections on the Eucharist," and "The Mysteries of Religion."

ABBADIE. I. Jacques, a French Protestant divine, born at Nay, in Béarn, in 1658, died in London, Oct. 6, 1727. After completing his studies at Sedan he went to Germany and Holland, and became pastor of the French church of Berlin. In 1690 he went to England, and, after preaching some time in London, was made dean of Killaloe in Ireland. He was a warm partisan of William III., and wrote a defence of the revolution and a history of the assassination plot. His most important works are: *Traité de la divinité de Jésus Christ*, and *Traité de la vérité de la religion chrétienne*. **II. Antoine Thomsen and Arnaud Michel d'**, French explorers, brothers, born in Dublin, Ireland, in 1810 and 1815. Their father, a Frenchman temporarily residing in Dublin, returned with them to France in their early childhood. In 1835 Antoine explored Brazil on a mission from the academy of sciences, while Arnaud travelled in Algeria. The two brothers happening to meet at Alexandria in 1837, they set out on an exploring expedition to Abyssinia, which lasted till 1845, and afterward passed three years in the Galla country. A rumor of their death caused a third brother, Charles, to proceed to that country, where he found them; and in 1848 they returned to France. A joint work of the two brothers appeared in 1860-'63, under the title of *Géologie d'Éthiopie*. Many of their writings are contained in the *Bulletin* of the Paris geographical society, including *Notes sur le haut fleuve Blanc*, published separately in 1849. The English expedition to Abyssinia led Arnaud d'Abbadie to publish in 1868 *Douze ans dans la Haute-Éthiopie*. The two brothers reside, when in France, at Urugne, a village in the Basses-Pyrénées.

ABBAS I., the Great, fifth shah of Persia of the dynasty of the Sofis, born in 1557, died

Jan. 27, 1628. He succeeded to the throne on the murder of his two elder brothers in 1587. He conquered Gilan, Mazanderan, Khorassan, and a great part of Afghanistan; and by the victory of Bassorah in 1605 over the Turks, and in many successive campaigns, he gained extensive accessions of territory all along the western frontier. Shah Abbas constructed the great highroad of Mazanderan, 300 miles long and 40 feet wide, of which parts still remain. He suppressed the Kurglis, a body similar to the Turkish janizaries; he fomented the sectarian differences of the Shiah and the Sunnis, and reduced the dogmas of the Shiah into the form of a creed. His fame extended to Europe, and ambassadors were sent to him from every court. He was not exempt from the vices of oriental despotism. Among other crimes, he put to death his eldest son, leaving his throne to his grandson, Sefy Mirza.

ABBAS BEN ABD-EL-MOTTALIB, paternal uncle of Mohammed, born at Mecca in 566, died in 652. He was the progenitor of the Abbasside dynasty, but not known as such until an adventurer, requiring a title to his usurpations, traced his descent to him. He was only four years the senior of Mohammed, and was yet a pagan when the prophet commenced his religious career, and long hesitated to espouse his nephew's cause. In the battle at the well of Bedr Abbas fought against his nephew, and was taken prisoner. So soon, however, as Mohammed's career seemed prosperous, the uncle gave in his adhesion, and became one of the most zealous supporters of the new faith. His influence and mediation brought over the family of the Koreishites; for when Mohammed, at the head of a powerful force, was about laying siege to Mecca, Abbas went forward, and not only demonstrated to Abu Sofian the inutility of resistance, but induced him to come to Mohammed's camp and to have a personal interview, which ended in Abu Sofian's making the profession of faith on behalf of himself and his kinsmen. When Mecca surrendered to Mohammed, the holy well Zemzem was retained, in deference to Abbas, its keeper, though other pagan rites and superstitions were swept away. At the battle of Honein Abbas rallied the fugitives and recovered the fortune of the day. At Mohammed's funeral he was chief mourner. Caliph Omar, on occasion of a terrible drought, took his hand, and prayed to Allah by the virtues of Abbas to have pity on the perishing people. Caliph Othman also, when he met the patriarch, dismounted.

ABBAS MIRZA, a Persian prince and warrior, born in 1783, died in 1833. He was the second and favorite son of Feth Ali, shah of Persia. He was the declared enemy of Russia, and commanded the armies of his father in the wars with that power in 1811-'13 and 1826-'8, but his campaigns proved unsuccessful. In 1829 the populace of Teheran murdered the Russian embassy, and Abbas Mirza voluntarily went to St. Petersburg to give satisfaction, but was dis-

missed honorably. He was amiable and chivalrous. He was nominated by his father heir to the throne, excluding his elder brother; but the father survived both.

ABBAS PASHA, viceroy of Egypt, grandson of Mehemet Ali, and nephew of Ibrahim Pasha, born in 1813, died July 12, 1854. He took an active part in the Syrian wars of his grandfather, but without distinguishing himself. After the brief reign of Ibrahim Pasha, Mehemet Ali's eldest son, Abbas ascended the viceregal throne, as hereditary successor, in 1848. He undid in many respects the work of Mehemet Ali, dismissed his European officials, and manifested an arbitrary, capricious, and cruel disposition. He succeeded, however, in disarming his adversaries at Constantinople, who endeavored to cripple him and reduce Egypt to a more inferior condition. In the Crimean war he aided the sultan. His death was sudden, and probably violent.

ABBASSIDES, caliphs of Bagdad, the third Mohammedan dynasty, founded by Abul Abbas as-Saffeh (the Bloody), who claimed the caliphate as lineal descendant of Mohammed's uncle Abbas, whence the name. He was proclaimed by his adherents at Cufah in 749, and afterward defeated and put to death the last Ommiyade caliph, Merwan II., all but two of whose family were treacherously slaughtered. He died in 754, and his descendants to the number of 36 reigned till 1258, when the last, Mostasem, was expelled from the throne by Hulaku Khan. The line includes the illustrious names of Al-Mansour, Haroun al-Rashid, and Al-Mamoun; but from the 10th century they had sunk to the position of mere spiritual chiefs of Islam, all political power being wielded by the emir el-ouma, or commander-in-chief. After their deposition at Bagdad, Ahmed, a member of the family, fled to Egypt, where he was recognized as caliph, and his descendants nominally reigned there, under the protection of the Mamelukes, till 1517, when Egypt was conquered by the Turks. Motawakkel, the last caliph, was carried to Constantinople, but allowed to return to Cairo, where he died in 1538.

ABBATUCCI, I. Jacques Pierre, a French general, born in Corsica in 1726, died in 1812. He was a rival and political opponent of Paoli, but submitted to his control in the war with the Genoese. After the French conquest, which he resisted at first, he accepted a commission in the royal army, and was subsequently appointed to protect Corsica against the attempts of Paoli and the English. After the capture of Toulon he resigned and returned to France, where he was made general of division. He remained there till 1796, when, the English leaving Corsica, he went home. **II.** Charles, son of the preceding, born in 1771, died Dec. 3, 1796. He served in the early part of the revolution as artillery officer on the Rhine, and in 1794 was Pichegru's adjutant. He was made general of brigade

for bravery in 1796, and afterward general of division for defeating the corps of the prince of Condé. He died from a wound received in an engagement with the Austrians at Hünningen, where Moreau caused a monument to be erected to his memory. **III.** Jacques Pierre Charles, a diplomatist, nephew of the preceding, born in Corsica, Dec. 22, 1791, died Nov. 11, 1857. Under the restoration he was a law officer in Corsica. After the revolution of 1830 he was appointed presiding judge at Orleans, and from 1839 was its representative in the chamber of deputies. He was a leader of the opposition to Guizot's ministry, and afterward of the reform banquets. After 1848 he was conspicuous in the national assembly by his opposition to the social-democratic movement. He subsequently became a zealous supporter of Louis Napoleon, and after the *coup d'état* was appointed by him minister of justice and keeper of the seals, Jan. 22, 1852. His sons, CHARLES (born March 25, 1816), ANTOINE DOMINIQUE, and SÉVERIN, all figured under the second empire as active Bonapartists, the last chiefly as representative from Corsica.

ABBÉ, the French word for abbot. Before the revolution of 1789, any Frenchman who chose to devote himself to divinity, or even to finish a brief course of study in a theological seminary, became an abbé, waiting hopefully for the king to confer on him the benefice of an abbey—that is, a certain portion of the revenues of a monastery. In the mean time he engaged in any and every kind of literary labor, exerted an important influence upon society, and was to be met with everywhere—at the court of the monarch, the public tribunals, the salon of the fashionable lady, the opera, the playhouse, and the café. An abbé was to be found in almost every wealthy family, either as the friend of the house or the private tutor of the children. There were many good and noble abbés, who acquired distinction as theologians, poets, and savants; but as a class they subjected themselves to popular suspicion and literary satire; and with the revolution they disappeared, though the title is still sometimes used as a phrase of politeness.—**ABBÉS COMMENDATAIRES** was the title of the 225 abbots appointed by the king of France. Each received one third of the revenues of a monastery, but he could not interfere with the *prieur claustral*, who had exclusive control. The *abbayes des savants* were less important sinecures, applied as pensions for scholars and untitled scions of aristocracy.

ABBEOKUTA, or Abeakutah, an independent city of central Africa, in the Egba district of Yoruba, with a small territory containing several minor towns, on the Ogoon, which separates it on the W. from Dahomey, about 50 m. N. of Lagos, and 110 m. E. S. E. of Abomey; pop. of the city estimated by Major Burton in 1861 at 150,000, and of the whole state at 200,000. The city stands on a granite formation 567 feet above the sea level, and is

surrounded by a mud wall six feet high thatched with palm leaves, 20 m. in circumference and enclosing much farming land. The name is derived from a flat rock 600 feet long covering the top of a high hill and projecting at the sides. The streets are generally narrow and very irregular and dirty. The houses are built of dried mud and thatched, with 10 to 20 rooms, surrounding an inner court where sheep and goats are kept. Several trades are carried on in a primitive way, and there are unions of smiths, carpenters, weavers, dyers, and potters, the last two composed of women. Regular markets are held, with very active traffic, chiefly by women, in cooked and uncooked food, vegetable oils, shea or tree butter, raw cotton, grass and other cloths, manufactures of excellent leather, cutlery and other European manufactures, and many other articles. The currency is cowry shells, but in 1867 it was proposed to introduce copper coins. Caravans go from Abbeokuta to Lake Tchad and Timbuctoo, respectively 800 m. (direct) N. E. and 850 m. N. N. W. The town is at the head of navigation on the Ogoon, which is ascended by light steamers during eight months in the year. The principal exports are palm oil and shea butter. The native cotton plant is perennial and the fibre good, and great efforts have been made to stimulate its cultivation. In 1859-'60 the quantity sent to England was about 2,300,000 lbs., but it soon fell off to about 400,000 on account of local war and indolence.—The government of Abbeokuta is entirely elective. There is a king, whose functions are chiefly judicial. The army is commanded by an almost independent general (*balogun*), with elected war captains. There is a sort of legislature composed of the so-called Ogboni lodges (of which there is one in each town) and the war captains, which controls the revenue and taxation, and is said to possess unlimited power. The income of the state consists of taxes on products collected at the gates, amounting to about 1 per cent. The religion of most of the people is fetishism, but missions have been established by the Wesleyans, Episcopalian, and Baptists, whose converts in 1861 numbered about 1,500. They publish a newspaper in the Egba tongue, and there is a church built of wood with a mud steeple and a bell. The missionaries were temporarily expelled by a mob in 1867.—Abbeokuta was founded in 1825 by refugees from numerous Egba towns which had been destroyed in war and many of their inhabitants carried off as slaves. Its people opposed the slave trade, established commerce with the English at Badagry and Lagos, and have successfully withstood many attacks from neighboring states, especially Dahomey and Ibadan. The king of Dahomey suffered disastrous defeats under its walls in 1851 and 1864.

ABBESS, the female superior of a convent of nuns ranking as an abbey, in some of the

more ancient orders. An abbeſs is ſolemnly bleſſed and inducted into office by a biſhop, and uſes the ring, croſs, and crozier.

ABBEVILLE, a well built, fortified town of France, in the department of Somme, on the river Somme and the Northern railway, 25 m. N. N. W. of Amiens; pop. in 1866, 19,385. The town contains a fine but unfinished Gothic cathedral, with other public edifices, and among its manufactures is one of cloth founded by Colbert in 1669. Vessels of 300 tons burden sail up the Somme to Abbeville. In 1259 peace was here concluded between Louis IX. of France and Henry III. of England.

ABBEVILLE, a W. N. W. county of South Carolina, bounded S. W. by the Savannah river, and N. E. by the Saluda; area, 960 sq. m.; pop. in 1870, 31,129, of whom 20,213 were colored. The soil is generally fertile, well watered, and well cultivated. The Greenville and Columbia railroad runs through the county. The productions in 1868 were 4,044,713 lbs. of cotton, 324,850 bushels of corn, 52,686 of wheat, 51,374 of oats, and 23,471 of sweet potatoes. The total value of property in 1870 was \$7,165,354. Capital, Abbeville.

ABBO CERNUUS, or *Abbon the Crooked*, a French monk of St. Germain des Près, died in 923. He was the author of an epic poem of some historical value, in Latin, descriptive of the siege of Paris by the Northmen in 885-'7, at which he was present. A French translation of it has been published by Guizot.

ABBO FLORIANENSIS, or *Abbon of Fleury*, a French monk, abbot of Fleury, and author of "Lives of the Popes," born near Orleans about 945, slain Aug. 13, 1004, while striving to quell a fray. He was several times engaged in controversies with the bishops as champion of the rights of his order. In 986, and again in 996, Abbo was sent to Rome by King Robert, to persuade the pope to abandon his intention of placing the kingdom under interdiction, and was successful in each case.

ABBOT (from the Semitic *ab* or *abba*, father), a prelate of high rank in the Roman Catholic church, who governs a principal monastery of one of the old religious orders, which may also have minor convents depending on it. An abbot is solemnly consecrated by a bishop, though this is regarded as a merely ecclesiastical and not a sacramental rite. Abbots are allowed to use the mitre, pastoral cross, ring, and crozier, and to celebrate pontifical mass, and are styled right reverend. Some of them in former times exercised a quasi-episcopal jurisdiction over a small district, and were allowed to confer tonsure and minor orders. During the middle ages many abbots, especially in England, were powerful feudal barons. In modern times they are simply superiors of religious houses. In ecclesiastical councils an abbot can speak, but not vote.

ABBOT, Abiel, D. D., an American clergyman, born in Andover, Mass., Aug. 17, 1770, died on the return voyage from Havana, June 7,

1828. He graduated at Harvard university, and in 1794 became minister of the Congregational society in Haverhill, where he remained eight years. In 1802 he took charge of a parish in Beverly, and passed the remainder of his life as pastor in that place. He was entirely free from sectarian bitterness. He was the author of a series of "Letters from Cuba" (8vo, Boston, 1829), and a number of sermons.

ABBOT, Benjamin, LL. D., an American teacher, for 50 years principal of Phillips academy at Exeter, N. H., born about 1763, died at Exeter, Oct. 25, 1849. He graduated at Harvard college, and took charge of the academy, which he conducted till 1838.

ABBOT, Charles, Lord Colchester, from 1802 till 1817 speaker of the British house of commons, born Oct. 14, 1757, died May 8, 1829. He served through a long and useful career in parliament, occupying at different times offices of honor and emolument. He was the author of one or two treatises on juridical reform. In 1817 he retired from the speakership, and was raised to the peerage as Baron Colchester.

ABBOT, George, archbishop of Canterbury, born at Guildford, Oct. 29, 1562, died at Croydon, Aug. 5, 1633. In 1597 he was appointed master of University college, Oxford, and was three times vice chancellor. In 1604, when by order of King James the translation of the Bible was commenced, Abbot was one of the eight divines to whom the whole of the New Testament except the Epistles was intrusted. In 1609 he was made bishop of Lichfield and Coventry; in January, 1610, bishop of London; in November following, archbishop of Canterbury. He steadfastly opposed King James's project of a divorce between Lady Frances Howard and the earl of Essex, and

combated the royal decree permitting Sunday sports. Laud was his bitter enemy. While visiting Hampshire for the restoration of his health, he accidentally shot a gamekeeper with the arrow aimed at a deer; and this misfortune, which was made the subject of a judicial inquiry and a royal pardon, preyed on his health and spirits during the rest of his days.

ABBOT, Gorham Dummer, LL. D., an American teacher and author, brother of Jacob and J. S. C. Abbott, born in Brunswick, Me., Sept. 3, 1807. After studying theology at Andover he made the tour of the United States and several voyages to Europe, in order to examine the systems and state of public education, as well as the variety, extent, and character of the issues of the press. In 1837 he became pastor of the Presbyterian church at New Rochelle, N. Y.; in 1841-'3 was travelling agent of the "American Society for the Diffusion of Useful Knowledge"; and in 1843 commenced the "Abbot Collegiate Institute" for young ladies in New York, afterward called the "Spingler Institute." He retired from teaching in 1866. He has written "Pleasure and Profit," "Prayer Book for the Young," "Mexico and the United States, their Mutual Relations and Common Interests" (8vo, 1869), and edited several educational and periodical works. (See ABBOTT.)

ABBOT, Samuel, a wealthy Boston merchant, one of the founders of the Andover theological seminary, born at Andover in 1732, died April 30, 1812. In 1807 he made a donation of \$20,000 toward establishing the seminary, and at his death left it \$100,000 in addition. He also gave away large sums for various charitable objects.

ABBOTSFORD, the seat of Sir Walter Scott, from which his baronet's title was taken. It

Abbotsford.

is situated in the parish of Melrose, in Roxburghshire and Selkirkshire, on the right bank of the Tweed, and in the neighborhood of the abbeys of Melrose, Jedburgh, and Dryburgh, and the towns of Selkirk and Galashiels. Sir Walter bought the estate in 1811, built the mansion, and gave it its present name, adopted from an adjoining ford in the Tweed. The house is irregular, and after the pattern of the old English manor houses; flourishing plantations hem it round, and a beautiful haugh or meadow on the opposite side of the Tweed forms its immediate prospect. The external walls of the house and garden are intercalated with antique carved stones taken from old castles and abbeys. The inside was decorated with beautiful paintings, the work of D. B. Hay of Edinburgh, and a library of curious works and British antiquities. Abbotsford was occupied by James Hope Scott, Esq., and his wife, the sole surviving granddaughter of Sir Walter Scott, until that lady's death, Oct. 26, 1858. Since that period, pending the minority of Miss Scott, the only surviving child, the mansion has been let for the use of a Roman Catholic seminary for girls.

ABBOTS-LANGLEY, a parish in Hertfordshire, England, 21 m. N. of London, noted as the birthplace of Nicholas Breakspare (Pope Adrian IV.), the only Englishman who ever occupied the holy see. "The Booksellers' Retreat" in this place is an institution founded by English booksellers as a home for decayed members of the trade.

ABBOTT, a family of American writers, whose name was originally spelled Abbot. **I. Jacob**, born at Hallowell, Me., Nov. 14, 1803. He graduated at Bowdoin college, Brunswick, Me., in 1820, and studied divinity at the theological seminary in Andover, Mass. From 1825 to 1829 he was professor of mathematics and natural philosophy in Amherst college, and afterward took charge of the newly founded Mount Vernon school for girls in Boston. In 1834 he engaged in organizing a new Congregational church in Roxbury (the Eliot church); and about 1838, relinquishing the pastoral charge to his brother John S. C., he removed to Farmington, Me., and has since devoted himself almost exclusively to literary labor, chiefly in the production of books for the young. For several years he has resided in New York. A complete catalogue of his works would considerably exceed 200 titles. Many of them have been serial, each series comprising from 3 to 36 volumes. Among them are the "Young Christian" series (4 vols.), the "Rollo Books" (28 vols.), the "Lucey Books" (6 vols.), the "Jonas Books" (6 vols.), the "Franconia Stories" (10 vols.), the "Harper's Story Books" (36 vols.), the "Marco Paul Series" (6 vols.), the "Gay Family" series (12 vols.), the "Juno Books" (6 vols.), "Rainbow and Lucky" series (5 vols.), and 4 or 5 other series of 5 or 6 volumes each; "Science for the Young" (4 vols.

issued, "Heat," "Light," "Water and Land," and "Force"); "A Summer in Scotland"; "The Teacher"; more than 20 of the series of illustrated histories to which his brother John S. C. contributed, and a separate series of histories of America in 4 volumes. He has also edited, with additions, several historical text books, and compiled a series of school readers.

II. John Stephens Cabot, brother of the preceding, born in Brunswick, Me., Sept. 18, 1805. He was also educated at Bowdoin college and Andover theological seminary, graduating from the former in 1825. He was ordained to the ministry in the Congregational church in 1830, and was settled successively at Worcester, Roxbury, and Nantucket, Mass. His first published work, "The Mother at Home," appeared in 1833, and was followed not long after by "The Child at Home." In 1844 he relinquished the pastorate, and devoted himself exclusively to literature, but has since occasionally resumed his ministerial labors for brief periods, and, in 1866-'8 acted as stated supply in New Haven. With few exceptions his works have been professedly historical. The principal of them are: "Practical Christianity"; "Kings and Queens, or Life in the Palace"; "The French Revolution of 1789"; "The History of Napoleon Bonaparte" (2 vols.); "Napoleon at St. Helena"; "The History of Napoleon III." (1868); 10 vols. of illustrated histories; "A History of the Civil War in America" (2 vols., 1863-'6); "Romance of Spanish History" (1870); and "The History of Frederick the Second, called Frederick the Great" (1871). Most of Mr. Abbott's books have had a large sale, and several of them have been translated into many languages.

III. Gorham D. See **ABBOT**. **IV. Benjamin Vaughan**, son of Jacob, a lawyer, born in Boston, June 4, 1830. He was educated in New York, and admitted to the bar in 1851. He has produced many volumes of reports and digests of state and United States laws and decisions of the higher courts of New York. He is now (1872) a member of the national commission for revising the laws of the United States, and is also preparing a National Digest.

V. Anstin, brother of the preceding, also a lawyer, born in Boston, Dec. 18, 1831. He was admitted to the New York bar about 1852, entered into partnership with his brother, and has cooperated with him in the preparation of legal treatises, compilations, and digests. He has also occasionally contributed to lighter literature, his earliest ventures being two joint novels entitled "Concent Corners" and "Matthew Caraby," in which his brothers Benjamin and Lyman participated. **VI. Lyman**, brother of the preceding, born in Roxbury, Mass., Dec. 18, 1835. He graduated from the university of the city of New York in 1853, studied law, and went into partnership with his brothers in 1856; but he afterward studied theology with his uncle, the Rev. J. S. C. Abbott, and was ordained to the ministry in the Congrega-

tional church at Farmington, Me., in 1860. He was settled as pastor of the first Congregational church in Terre Haute, Ind., the same year, and remained there till 1865, when he was chosen secretary of the American union (freedmen's) commission, and held that office till 1868. He was also pastor of the New England church in New York city from 1866 to 1869, when he resigned, to devote himself to literature. He was associated with his brothers in the production of two novels, and has also published "The Results of Emancipation in the United States" (1867), "Jesus of Nazareth: His Life and Teachings" (1869), and "Old Testament Shadows of New Testament Truths" (1870). He has edited two volumes of "Sermons by Rev. Henry Ward Beecher," and "Morning and Evening Exercises," selected from the writings of the same author. He is now (1872) the editor of the "Literary Record" of "Harper's Monthly Magazine," and editor-in-chief of "The Illustrated Christian Weekly," published by the American tract society.

VII. Edward, brother of the preceding, born in Farmington, Me., July 15, 1841. He was educated in New York, has contributed to periodical and other literature, and is one of the editors of "The Congregationalist," a leading Congregational newspaper published in Boston.

ABBOTT, Charles, Lord Tenterden, an English lawyer, born Oct. 7, 1762, died Nov. 4, 1832, He was appointed lord chief justice of the king's bench in 1818, and in 1827 was created a peer as Baron Tenterden. His treatise on maritime law is a standard work.

ABBREVIATIONS, certain contractions of various words and phrases, effected by omitting some of the letters or syllables. The object in view is the saving of time and space. They are found in every written language, but since the art of printing was discovered are much less used. The Romans called them *notæ*, and Lucius Annaeus Seneca made a list of them, embracing upward of 5,000. The abbreviations in most ordinary use are those of names and titles. Physicians and lawyers use them largely for the sake of despatch. The Jewish writers not only throw out letters and syllables, but often omit everything except the initial letter. They even take the initials of a continuous series of words, and, uniting them with the aid of vowels, make new words standing in the place of all those thus abridged. The monks of the middle ages used so many abbreviations in copying the works of the Greek and Latin writers, that only experienced persons can decipher them. The Germans use them to a greater extent than any other nation, for words in common use. Many words in modern languages originated in Latin abbreviations, which illiterate persons mistook for the words themselves. The following are the principal abbreviations in common use:

A. B. Artium Baccalaureus, A. C. Ante Christum, before Bachelor of Arts. Christ. Abp. Archbishop. Aoct. Account.

A. D. Anno Domini, in the year of our Lord.
Adj. Adjuvant.
Ad lib. Ad libitum, at pleasure.
Adm. Admiral.
Admr. Administrator.
Admx. Administratrix.
Æt. or Ætat. Ætatis, of age.
A. G. Adjutant General.
A. H. Anno Hegira, in the year of the Hegira.
Ala. Alabama.
A. M. Anno mundi, in the year of the world; Ante meridiem, before noon; Artium Magister, Master of Arts.
A. R. A. Associate of the Royal Academy.
Ark. Arkansas.
A. U. C. Anno urbis condite, or Ab urbe condita, in the year from the building of the city (Rome).
B. A. Bachelor of Arts.
Bart. or Bt. Baronet.
Bbl. Barrel.
B. O. Before Christ.
B. D. Bachelor of Divinity.
B. I. British India.
B. L. Bachelor of Law.
Bp. Bishop.
Brig. Gen. Brigadier General.
Bush. Bushel.
B. V. Blessed Virgin.
B. V. M. Blessed Virgin Mary.
C. Centigrade (thermometer).
Cal. California.
Cap. Capitulum, chapter.
Capt. Captain.
C. B. Companion of the Bath; Cape Breton.
C. E. Civil Engineer.
Cent. Centum, hundred.
Cf. Conferre, compare.
Chap. Chapter.
Chron. Chronicles.
C. J. Chief Justice.
C. O. D. Collect (or cash) on delivery.
C. G. H. Cape of Good Hope.
Col. Colonel; Colossians; Colorado.
Conn. or Ct. Connecticut.
Cor. Corinthians.
Cor. Sec. Corresponding Secretary.
Coss. Consules, consuls.
C. R. Civis Romanus, a Roman citizen.
Cr. Creditor.
C. T. Colorado Territory.
Ct. or Conn. Connecticut.
Cwt. Hundred weight.
D. (d.). Denarius, denarii, a penny, pence.
D. C. District of Columbia.
D. C. L. Doctor of Civil Law.
D. D. Doctor of Divinity.
Del. Delaware; delineavit, drew it.
Deut. Deuteronomy.
D. F. Defensor fidei, defender of the faith.
D. G. Dei gratia, by the grace of God.
Do. Ditto (Ital., said), the same.
Dr. Doctor; debtor.
D. T. Dakota Territory.
D. V. Deo volente, God willing.
Dwt. Pennyweight.
E. East.
Ecol. or Eccles. Ecclesiastes.
Eclus. Ecclesiasticus.
E. E. Errors excepted.
E. g. or Ex. gr. Exempli gratia, for example.
E. I. East India, or East Indies.
Eph. Ephesians.
Esl. Esdras.
Esq. Esquire.
Et al. Et alii, or alios, and others.
Etc. Etcetera, and so forth.
Et seq. Et sequentes, or sequentia, and the succeeding.
Ex. or Exod. Exodus.
Exr. Executor.
Ezek. Ezekiel.
F., or Fahr. Fahrenheit.
F. ar. A. M. Free and Accepted Masons.
F. A. S. Fellow of the Antiquarian Society.
F. D. Fidei defensor, defender of the faith.
F. G. S. Fellow of the Geological Society.
Fla. or Flor. Florida.
F. R. G. S. Fellow of the Royal Geographical Society.
F. R. A. S. Fellow of the Royal Astronomical Society.
F. R. S. Fellow of the Royal Society; L. of London; E., of Edinburgh; D. of Dublin.
F. S. A. Fellow of the Society of Antiquaries.
Ga. Georgia.
Gal. Galatians.
G. C. B. Grand Cross of the Bath.
Gen. General; Genesis.
G. M. Grand Master.
Gov. Governor.
Hab. Habakkuk.
Hag. Haggai.
H. B. M. His or Her Britannic Majesty.
Heb. Hebrews.
Hhd. Hogthead.
H. I. H. His or Her Imperial Highness.
H. M. S. His or Her Majesty's ship.
Hon. Honorable.
Hos. Hosea.
H. R. House of Representatives.
H. R. H. His or Her Royal Highness.
Ia. Iowa, (This should not be used for Indiana, but Ind.)
Ib. or Ibid. Ibidem, in the same place.
Id. Idem, the same.
Id. T. Idaho Territory.
I. e. Id est, that is.
I. H. S. Jesus Hominum Salvator, Jesus (Jesus) the Saviour of men. (Said to have originated from a misreading of the Greek ΙΗΣΟΥΣ for 'ΙΗΣΟΥΣ, Jesus.)

ABD, an initial word in proper names common to the Semitic languages. It signifies "servant," and is usually coupled with the name of the Divinity or of a moral attribute; thus, Abd-allah, "the servant of Allah;" Abd-cr-Rahman, "servant of the Merciful."

ABDALLAH BEN ABD-EL-MOTTALIB, an Arab merchant, father of Mohammed, born at Mecca about 545, died in 570. In youth, according to the Moslem legend, he narrowly escaped sacrifice at his father's hands, who, having but this one child, had made a vow to the gods that if they would grant him ten children, he would sacrifice one to them. The children came, and the lot, being taken, fell on Abdallah, thgn 24 years old. The father was on the point of fulfilling his vow, when by the advice of his friends he stayed his hand, and consulted a wise woman, who directed him to place ten camels, the price of blood among the Arabs, on one side, and his son on the other, and to cast lots between them; and as often as the lots should be against the youth, he was to add ten more camels. The experiment was tried, and the lot was against Abdallah ten times; the father sacrificed one hundred camels and saved his son. Immediately after this escape, Abdallah married Amina, daughter of Walib, chief of the tribe of Benu Zahra. On the evacuation of Mecca by the Abyssinians, who had invaded the country, he was sent by his father to Medina, then called Yathreb, to buy provisions for the famished Meccaites, who had been obliged to fly to the mountain fastnesses. Abdallah died on the journey, leaving his wife pregnant with her first child. That child was Mohammed.

ABDALLAH BEN ZOBAÏR, ruler of Mecca, born about 622, died in 692. He was the first born of the disciples of Mohammed after the hegira, and his advent was a matter of great rejoicing. He was the son of Zobaïr, a friend and companion of Mohammed, and of Asma, the sister of Ayesha, the prophet's favorite wife. He was thus Mohammed's nephew by marriage, and was brought up under his immediate tutelage. After Mohammed's death, the question of succession was one of great moment. On the death of the prophet's immediate successors, and the election of Ali, Mohammed's nephew and son-in-law, to whom Ayesha was decidedly opposed, Abdallah sided with his aunt and resisted Ali's claims. He was, however, severely wounded in a contest with the rival faction; but on the assassination of Ali he boldly renewed his opposition to Moawiyah, and on his

death raised the standard of revolt against Yezid, his successor. He seized upon the holy city, and maintained himself against both the remonstrances and the arms of the caliph. At this early period there were three distinct governments in the territories conquered by the Arabs, in Persia, Syria, and Arabia. Abdallah's chief opponent was Yezid, caliph of Damascus. In the siege which he sustained at Mecca, the temple of the holy Caaba was destroyed by the assailants, and the death of Yezid alone saved the city from capture. Abdallah was now acknowledged sultan and caliph of Mecca by the Arabs, and rebuilt the city and temple, not without opposition from his superstitious subjects, who considered it sacrilege to touch the stones of the sacred edifice. He completed the restoration in 685. Yezid's son, Moawiyah II., abdicated in favor of Merwan, on whose death his son Abd-el-Malek ben Merwan succeeded him, and pushed the war vigorously against Abdallah, by whose anathemas Abd-el-Malek's subjects, when they made the pilgrimage to Mecca, were greatly influenced or scandalized. Abd-el-Malek vanquished Abdallah's brother and lieutenant Mozab ben Zohair in the plains of Persia, added Irak to the caliphate of Damascus, and despatched an army against Abdallah at Mecca. The holy city was a second time besieged, and resisted for several months. Abdallah, at the age of 70, defended himself to the last, and when the city was taken by storm retired to the Caaba, where he was killed by a blow on the head from a tile. He is described as brave to rashness and crafty to perfidy.

ABD-EL-HALIM, known as **HALIM PASHA**, an Egyptian prince, son of Mehemet Ali and a white slave woman, born at Cairo in 1826. He was educated at Paris, and of late resides near Cairo, in a magnificent palace celebrated for its beautiful pleasure grounds. The sultan has often taken his part in his family quarrels with his relatives Abbas and Saïd, the late viceroys, and Ismail Pasha, the present khedive. Abbas (1848-'54) endeavored even to appropriate Halim's property, but restored it to him at the request of the sultan, who also conferred upon Halim the rank of pasha and mushir (field marshal). Under Saïd he was for a short time a member of the family council, until that viceroy was formally recognized by the sultan (July, 1854). In 1855-'6 he officiated for a brief period as governor general at Khartoom. Since the accession of his nephew Ismail (1863), Halim has been more persecuted than in the reign of Abbas Pasha. In 1866, when the sultan consented to modify the organic Mohammedan laws of succession in favor of a direct line of hereditary rulers in Egypt, it was hoped that this would do away with the jealousy of Ismail Pasha against his uncle, but the khedive remains unfriendly.

ABD-EL-HAMID, the Arabic name adopted by **Du CouRET**, a French traveller, on his becoming a Mohammedan. He was born in 1812 at Hü-

ningen, in Alsace, travelled from 1834 to 1847 in the East, was sent in 1848 on a mission to Timbuctoo, a report of which appeared in 1853 (*Mémoire à Napoléon III.*), and published in 1855 the story of his Arabic pilgrimages (*Mémoires et la Mekke*, 3 vols.), which was worked up by Alexandre Dumas in his *Pèlerinage de Hadji Abd-el-Hamid Bey* (2 vols., 1855).

ABD-EL-KADER, an Arab emir in Algeria, born near Mascara in 1806 or 1807. He was the descendant of an ancient family of Marabouts, and the son of Mahiddin, an influential emir, who, suspected of plotting the subversion of Turkish rule, was compelled to retire with his son to Cairo in 1827. When Abd-el-Kader returned from this exile Algiers had been captured by the French. A man of remarkable powers and accomplishments, and of the greatest bravery, the young emir soon became the leader of his countrymen, and organized among them a system of resistance to the French invaders, whom he began to harass at the head of his own and the neighboring tribes. Encouraged by the failure of an attack which Gen. Boyer, commandant of Oran, made in the spring of 1832 upon his stronghold at Tlemcen, Abd-el-Kader conducted his attacks upon the French on a larger scale, and with such skill and bravery that the admiring Arabs proclaimed him chief of the believers. For two years he continued operations, but in 1834 Gen. Desmichels, Boyer's successor, by causing a defection of the native tribes, obliged him to make peace, France acknowledging his sway over the tribes west of the Shelliff. Abd-el-Kader now spent a short period of quiet in introducing European discipline and tactics among his followers. But he soon crossed the Shelliff during a successful war with a native chief; and the French, alarmed by his growing power, again began hostilities under Gen. Trézel, who was sent to replace Desmichels. Trézel, marching toward Mascara, was surprised and utterly defeated by Abd-el-Kader in the defile of Muley Ismail. Marshal Clauzel was now made governor of Algiers. In December and January, 1835-'6, he succeeded in reaching and destroying Mascara, and in capturing Tlemcen, where he left a garrison; but this accomplished, he was obliged at once to make a disastrous retreat to Oran. In April, 1836, Abd-el-Kader utterly defeated Gen. d'Arianges near Tlemcen, and obliged him to fall back on a fortified camp he had established on the Tafna to keep open the communication between the French garrison of Tlemcen and their base of supplies. In this camp the general was shut up by Abd-el-Kader's troops, and compelled to remain until relieved by Gen. Bugeaud. This officer was now appointed to the command in Algiers, and conducted the war with great success, first defeating Abd-el-Kader July 7, 1836, and finally compelling him in May, 1837, to conclude a peace by which he acknowledged French sovereignty, though himself confirmed as emir of Oran, Titteri, and part of Algiers. But he was

not content, and in 1839 war was renewed. After desperate fighting, Abd-el-Kader was defeated everywhere; and in 1842 he was driven from Algeria and took refuge in Morocco, where he induced the emperor to aid him against the French. But the Moorish ruler, being utterly defeated by the French army at Isly, Aug. 14, 1844, was obliged, in order to save himself from the vengeance of France, to turn against the emir; and Abd-el-Kader, who now defied both the French and the Moors, soon found himself deserted by all but his own tribe, and beaten at every point. After continuing the contest as long as possible, he was finally captured and sent to Paris in 1848, although he had surrendered only on condition that he should be sent to Egypt or St. Jean d'Acre. He was kept in France until released by Louis Napoleon in 1852, with a pension of 100,000 francs, on condition that he should not return to Algeria or again take up arms against France. He went to Broussa in Asia Minor, and when that town was destroyed by an earthquake in 1855, he removed to Constantinople. He has been since 1852 on the best terms with the French government, and in 1855 visited Paris during the industrial exposition. He subsequently took up his residence in Damascus, where he distinguished himself by generously aiding the Christians during the bloody riots in the summer of 1860. In 1864 he went to Egypt, where he was presented with a piece of land by M. de Lesseps, projector of the Suez canal. During this journey he was also made a member of the order of Freemasons. In 1865 he went to England, and in 1867 attended the great exposition in Paris. In 1870 he offered his sword to the French against the Germans, but the offer was declined. In October, 1871, he addressed a letter to M. Thiers declining to visit France on the ground of ill health, but making suggestions relative to the condition and government of Algeria. Of his 24 children most have died. One of his daughters has become a convert to Christianity. Abd-el-Kader is the author of a book of philosophico-religious meditations, written in exile, in Arabic, and translated into French under the title of *Rappel à l'intelligent, Aris à l'indifférent* (Paris, 1858).

ABD-EL-WAHAB, founder of the Mohammedan sect of Wahabees or Wahabites, born of poor parents, in the Arabian province of Nedjed, about 1691. After long travels through various parts of Arabia, Syria, and Mesopotamia, he finally taught his new religious doctrines in his native region, and died in 1787. (See WAHABITES.)

ABDERA (now *Polystilo*), an ancient city of Thrace, on the S. coast, at or E. of the mouth of the river Nestus. It was a flourishing town in the times of the Persian wars with Greece, and preserved its importance under the Romans. Its inhabitants were proverbial for their ignorance and stupidity, from which ill repute they were not saved by the lustre that Democritus, Protagoras, Anaxarchus, and Illeatæus

threw around the name of the town as their birthplace. Lucian, La Fontaine, and Wieland have made them subjects of their satire. Coins of this city are numerous.

ABDERRAHMAN I., surnamed the Wise, the first ruler of the family of the Ommiyades in Spain, born at Damascus in 731, died in 787. After the massacre of his family in the East he retired to Mauritania, where he remained in privacy until he was called to Spain by a deputation of friends, who were tired of anarchy. Abderrahman with a handful of relatives landed at Almunecar on the coast of Andalusia in 755, and soon found himself at the head of a large army. He entered Seville, and was acknowledged as sovereign. Next he advanced against Yusuf el-Feri, the most powerful of the rival emirs, whose army, though of greatly superior numbers, he entirely defeated, firmly establishing himself on the throne of Cordova. It was during these internal dissensions in Spain that the Mohammedans were finally driven out of France, and forced to recross the Pyrenees. The eastern caliphs, who always kept up the idea of maintaining the right of spiritual and temporal rule over the Spanish Moors, anathematized Abderrahman, and despatched two expeditions against him, but in vain. The kingdom of Cordova was at peace when Charlemagne fruitlessly crossed the Pyrenees. Abderrahman built the magnificent mosque of Cordova, designed by himself, at which he is said to have labored an hour a day with his own hands. He planted the first palm tree in Cordova, the stock from which all those now in Spain are descended.

ABDERRAHMAN, sultan of Morocco, born in 1778, died in August, 1859. He succeeded to the throne in 1823, on the death of his uncle, Muley Suleiman. At his succession the practice of paying tribute to the Barbary states and Morocco by independent Christian states, as a guarantee against piracy, had not ceased; but Abderrahman was compelled by the Austrians in 1828 to abandon the claim. In 1844 the prolonged resistance of Abd-el-Kader to the French invasion in Algeria involved Morocco in war with France, and Mogadore and Tangier were bombarded by a French fleet. The contest was terminated by the battle of Isly, Aug. 14, 1844, in which only Abd-el-Kader's Arabs fought well on the Moslem side. Abderrahman was now compelled to turn his arms upon the Algerian emir, and, having collected a large army, finally drove him beyond the frontiers of Morocco into French captivity. Abderrahman was succeeded by his eldest son, Sidi Mohammed, born in 1803.

ABDIAS, of Babylon, the supposititious author of a book called *Historia Certaminis Apostolici* (published at Basel in 1551), in which he asserted that he had seen Christ, that he was one of the 70 disciples, that he had witnessed the deaths of several of the apostles, and that he accompanied St. Simon

and St. Jude into Persia, by whom he was made the first bishop of Babylon.

ABDICATION, the abandonment of a throne by a crowned head, was rare and generally compulsory in ancient times. The abdication of Diocletian and Maximian is the best known case in antiquity. Among modern princes who have more or less voluntarily laid down their crowns, we find Charles V. of Spain and Germany (1556); Christina of Sweden (1654); in Poland, John Casimir (1669); in Spain, Philip V. (1724) and Charles IV. (1808); in Savoy and Sardinia, Amadeus VIII. (1434), Victor Amadeus II. (1730), Victor Emanuel I. (1821), and Charles Albert (1849); in France, Napoleon I. (1814 and 1815), Charles X. (1830), and Louis Philippe (1848); in Holland, Louis Bonaparte (1810) and William I. (1840); in Bavaria, Louis I. (1848); in Austria, Ferdinand (1848). The most recent and one of the most remarkable of royal abdications is that of King Amadeus of Spain, who after a reign of two years became disgusted with the difficulties of his position, and on Feb. 11, 1873, resigned the crown for himself and heirs, and returned to his native Italy. Abdication, voluntary or compulsory, is considered by jurists as a personal act, which in no wise affects the right of succession.

ABDOMEN (Lat., of undetermined etymology), the lower part of the body, included between the level of the diaphragm and that of the pelvis. The abdomen consists of its walls or boundaries, the cavity embraced by them, and the organs or viscera included therein. The walls are constituted below by the pelvis, a strong basin-shaped bone with wide flaring edges, upon the upper surface of which the weight of the abdominal organs is sustained; behind by a part of the spinal column and the strong muscles attached to its sides; above by the diaphragm, a vaulted muscular sheet, which forms the partition between the cavity of the abdomen and that of the chest; and in front by the abdominal muscles and their integuments, extending from the lower part of the chest to the pelvis. In front and laterally, the abdominal walls are soft and flexible, being composed only of the skin, fatty tissue, fibrous membranes, and muscles; behind they are more solid and unyielding, owing to the bony framework of the spinal column, which here forms so large a part of their substance. For convenience of anatomical examination and reference, the abdomen is divided externally into three nearly equal transverse bands or zones, an upper, middle, and lower; these zones being again divided into three nearly equal parts or "regions," namely, one middle and two lateral regions in each zone. In the upper zone the middle region is the *epigastrium* (Gr. *επα*, over, and *γαστηρ*, the stomach), because a portion of the stomach is situated immediately beneath it; the two lateral regions of the same zone being the right and left *hypochondria* (*ὑπο*, under, and *χονδρος*, a cartilage), because these two re-

gions are beneath the cartilages of the lower ribs. In the middle zone, the median portion is the umbilical region, so called because it contains the umbilicus or navel; the two lateral portions are the right and left lumbar regions, or the loins. In the lowermost zone, the middle region forms the *hypogastrium* (*ὑπο* and *γαστηρ*), and the two lateral portions the right and left iliac regions, which are occupied on each side by the ilium, or flaring portion of the pelvis.—The cavity of the abdomen is lined by a very extensive and delicate membrane, the *peritoneum* (Gr. *περιτενειν*, to extend around), which is also reflected over the surfaces of the abdominal organs, as the covering of a chair or sofa may be reflected or extended over its cushion. In the case of those abdominal organs which remain fixed in their places, like the pancreas and the kidneys, the peritoneum simply passes over their anterior surfaces; but those which are movable, like the liver, stomach, and intestines, are more or less completely invested by it, some of them being attached to the posterior abdominal walls only by the double layer of peritoneum, returning upon itself after having covered their exterior. Thus these organs are covered, and the abdominal walls are lined, by opposite surfaces of the same continuous peritoneal membrane; and these surfaces are moistened by a minute quantity of serous fluid, which enables them to move gently to and fro upon each other, without causing friction or irritation of the parts. The organs contained in the abdomen are as follows: In the upper zone, the liver, stomach, spleen, pancreas, and the commencement of the small intestine; in the middle zone, the mass of the small intestine, with portions of the large intestine, the kidneys, and the suprarenal capsules; and in the lowermost zone, the remainder of the small and large intestines. The very last portion of the large intestine occupies the deeper parts of the cavity of the pelvis, together with the urinary bladder and the uterine organs.—Owing to the flexible character of the abdominal walls, much information may be obtained regarding the condition of the internal organs by external manual examination. If an organ be enlarged, indurated, or displaced, these changes may be detected by careful manipulation, and their increase or diminution may be determined from day to day. If one or more of them be inflamed, this condition is indicated by an unnatural tenderness on pressure; and the exact situation and character of the inflammation may often be fixed by observing whether the tenderness be superficial or deep-seated. Unnatural growths and tumors may be detected in the same way, and their origin ascertained in many cases with considerable approach to certainty. Penetrating wounds of the abdomen are very dangerous, because the contents of the stomach and intestines, if allowed to escape into the cavity of the peritoneum, pro-

duce an irritation and subsequent inflammation of the membrane; and this inflammation, spreading in every direction over the contiguous surfaces of the peritoneum, becomes so extensive and violent as almost invariably to produce fatal consequences. Nevertheless, surgical operations in which the cavity of the abdomen is opened, but in which care is taken to prevent the escape or dissemination of irritating substances, have often been performed with a successful result. Sudden and powerful blows upon the abdomen, especially in the region of the epigastrium, are also sometimes fatal, even when none of the internal organs are lacerated, owing to the depressing influence of the shock upon the nervous system.

ABDUL-AZIZ, sultan of Turkey, second son of Mahmud II., born Feb. 9, 1830. He succeeded his brother Abdul-Medjid, June 25, 1861. Like all heirs to the Turkish throne, his life until his accession was passed in seclusion, and little is known of him during that period except that he was fond of agricultural studies, and established a model farm at Scutari. On mounting the throne he was prodigal with promises of reform, dismissed the corrupt minister of finance, Riza Pasha, reduced his civil list, got rid of the seraglio, declared that he would not indulge in polygamy, and seemed to take a lively interest in ameliorating the condition of the people, and in purging public affairs from fraud and corruption. His intentions were excellent, and he was determined to give to his empire the benefits of European civilization. Hence his journey to France, England, and Austria in 1867, which tended to make him popular in those countries, but alienated from him the sympathies of orthodox Mussulmans. Disregarding the fanatical spirit of the opposition, he allowed foreigners, for the first time in Turkey, to hold real estate, established a public high school after a French model, enriched the capital with various scientific institutions, and endeavored to place the administration of justice upon a more solid basis by ordering the supreme court (1869) to draw up a civil code. In many respects, however, his good intentions were soon overborne by opposition, the power of ancient usages, and his own weakness. He recognized the independence and unity of Italy, negotiated treaties of commerce with England and France, crushed rebellion in Montenegro (1862) and in Crete (1868), and signed in 1871 the treaty of London denaturalizing the Black sea. He tolerated the accession to the Roumanian throne of Prince Charles of Hohenzollern as a matter of policy, but found much trouble in his relations with Egypt. In 1866, in consideration of a vast sum of money, he had, contrary to the Mohammedan law, granted to Ismail Pasha the right of succession to the viceregal throne in a direct line from father to son, while, instead of the title of viceroy, that of khedive was conferred upon him. A similar change was proposed for Turkey, so as to ena-

ble Yusuf, the eldest son of Abdul-Aziz, born in 1857 before his accession to the throne, to succeed him, contrary to the ancient institutions of the empire; but it was found impracticable, and the presumptive heir is consequently the sultan's eldest nephew, Mehemet Murad, born in 1840. Besides Yusuf, the sultan has four recognized children: Sultana Salikhe, born in 1862; Mahmond Jemil, born in the same year; Mehmed Selim, 1866; and Abdul-Medjid, 1868.

ABDUL-MEDJID, sultan of Turkey, born April 23, 1823, died June 25, 1861. He succeeded to the throne on the death of his father Mahmud II., July 1, 1839. Educated in the seclusion of the seraglio, his weak and almost feminine character, his kind disposition, his love of pleasure, his inexperience and want of knowledge, seemed to render him utterly unfit to rule. Mehemet Ali having a second time rebelled, his son Ibrahim had routed the Turkish army near Nizib, June 24, 1839, and was on his march against Constantinople, where a strong party was secretly conspiring to elevate him to the throne. At the same time the capudan pasha or grand admiral betrayed his trust by surrendering the entire fleet to Mehemet Ali. The intervention of England and the German powers checked the Egyptian designs, and by the treaties of July 15, 1840, and July 13, 1841, Turkey was formally admitted into the political system of Europe. The personal share of Abdul-Medjid in all these proceedings was very small indeed. During the earlier years of his reign he was scarcely more than a puppet in the hands of others; but he became keen enough to discern the purposes of his advisers, while his benevolent disposition made him anxious to do justice and to promote the welfare of his subjects. On Nov. 3, 1839, acting under the advice of Reshid Pasha, he convoked all the grand officers of the empire, the sheiks of the dervises, the three patriarchs of the Christian sects, the three high rabbis of the Jews, the foreign diplomats, the ulemas and mollahs, the trustees of all corporations at Constantinople, and citizens generally, around the pavilion of Gulhane in the imperial park, and there promulgated the *Hatti-Sherif* or fundamental law, the bill of rights, intended to be the basis of a political reconstruction. Equality before the law was guaranteed to all subjects of the sultan, without distinction of creed or nationality; an equitable mode of taxation was to be introduced; a just system of conscription was also promised. More than once the *Hatti-Sherif* was confirmed and repeated in new decrees; and in 1845 the sultan went so far as to call a kind of congress, consisting of representatives from different provinces of the empire. A board of education was instituted in 1845, and a system of free public schools established in 1846. On Feb. 18, 1856, the *Hatti-Humayun* was published, being the draught of a liberal constitution. While from 1840 to 1853 almost

every year of Abdul-Medjid's reign was marked by insurrections in one province or another, the court was the theatre of incessant intrigues, amid which the position of the sultan was scarcely more honorable or important than that of a nominally sovereign king in the East Indies. For several years he led a dissolute life, but afterward he appeared to mend his ways in some degree, and improved his education by studying French, mathematics, history, and music. European customs and fashions became more and more prevalent at court, concerts and Italian opera were established permanently, and in 1854 the sultan, "the supreme father of the faithful," even went to a ball. When in 1849 the defeated Hungarian patriots sought refuge on Turkish soil, Abdul-Medjid preferred running the risk of a formidable war to betraying those who had confided in the sacredness of hospitality as taught by Mohammed. He had seven sons and two daughters, but was succeeded, according to law, by his brother Abdul-Aziz.

ABECEDARIANS, a sect which appeared among the Anabaptists of Germany in the 16th century, led by one Storek, previously a disciple of Luther. They held that without the aid of study the Holy Spirit would convey directly to the understanding a knowledge of the Scriptures, and that therefore it was better not to know how to read. Carlstadt, a Wittenberg divine, and at one period of his life a bitter antagonist of Luther, is said to have contemned the Abecedarians by tearing off his doctor's gown and burning it.

ABÉKÉT, Gilbert Abbott, an English humorous author, born in London in 1810, died in Boulogne, April 28, 1856. He was called to the English bar in 1841. He was a contributor to both the London "Times" and "Daily News," and was special correspondent of the "Times" in a celebrated poor law inquiry, in which he displayed great judgment. He was one of the earliest contributors to "Punch," and wrote the "Comic Blackstone," comic histories of England and Rome, and a great number of burlesque plays. He was appointed one of the police magistrates of London. On his death the queen, on the recommendation of Lord Palmerston, granted his widow a pension of £100 a year.

ABEEL, David, D. D., an American clergyman, born in New Brunswick, N. J., June 12, 1804, died in Albany, N. Y., Sept. 4, 1846. He studied theology at the seminary in New Brunswick, and after preaching for more than two years at the village of Athens, N. Y., his health gave way, and in October, 1829, he sailed for Canton as a chaplain of the seaman's friend society, but at the end of a year's labor placed himself under the direction of the American board. He visited Java, Singapore, and Siam, studying the Chinese tongue, when his health failed him entirely, and he returned home in 1833 by way of England, visiting Holland, France, and Switzerland, and every-

where urging the claims of the heathen. He also assisted in England in forming the society for promoting female education in the East. In America he published a description of his life in China and the adjacent countries, and a work entitled "The Claims of the World to the Gospel." In 1838 he returned to Asia, and visited Malacca, Borneo, and other places, settling at Kolingsu. Once more his health gave way, and he returned home in 1845.

ABEGG, Julius Friedrich Heinrich, a German jurist, born in Erlangen, March 27, 1796, died in Breslau, May 29, 1868. In 1818 he received his legal doctorate, and in 1820 commenced delivering lectures at Königsberg. In 1826 he became professor of law at Breslau, and in 1846 was delegate of the legal faculty at Breslau to the Prussian national synod. He was a very influential writer upon criminal administration. One of his last works was *Entwurf einer Strafprozessordnung für den preussischen Staat* (Leipsic, 1865).

ABEL, the second son of Adam. He was a shepherd, and was slain by his brother Cain, from envy. It has been maintained by some fathers of the church that Abel never married; hence the sect of Abelites.

ABEL DE PUJOL. I. Alexandre Denis, a French painter, born in Valenciennes, Jan. 30, 1785, died in Paris, Sept. 28, 1861. He was a pupil of David, and achieved distinction as a historical painter of the older classical school. Many of his works may be found in French churches. **II. Adrienne Marie Louise Grandpierre Deverzy**, wife of the preceding, to whom she was married in 1856, born at Tonnerre, in the department of Yonne, in 1798. She was a pupil of her future husband, and made her debut in 1836 by a picture representing a painter's studio. She afterward painted portraits, a scene from Gil Blas, &c.—A son of Abel de Pujol, born about 1815, is also a painter.

ABÉLARD, or Abailard, Pierre, a French scholastic philosopher, born near Nantes, in Brittany, in 1079, died April 21, 1142. Having made early and rapid progress in the learning of the age, he relinquished his family inheritance in favor of his brothers, that he might be free from the cares of property, and have no impediment to the gratification of his thirst for knowledge. At the age of sixteen he betook himself to Paris, and inscribed himself among the pupils of William de Champeaux, a famous professor. In the public disputations which were the fashion of the day, Abélard had no superior. In a discussion on the origin and nature of ideas, he made such a brilliant display of ability, learning, and logical acuteness, that he endangered the supremacy of De Champeaux in the seat of learning where he had so long held sway; and his jealousy was at a high pitch when Abélard, though only 22 years old, opened a school of philosophy at Melun, near Paris, a favorite retreat of the court, which was well attended by students who deserted the other teachers. Abélard's

falling health compelled him for a time to retire to his native air; but so soon as he had recruited his strength, he returned to the scene of his triumphs, and resumed his place as pupil at the feet of his old master. De Champeaux became a monk, but still continued his secular pursuits, and the fiery debates were renewed, in which Abélard again came off victor. De Champeaux was made bishop of Châlons, and his new power was exercised to crush his adversary with other weapons than those of argument. The canon Fulbert had a niece of whose intellectual and personal accomplishments he was justly proud. Admiring the talents and distinction of Abélard, he invited him to complete the education of his beautiful niece. Abélard boasted that he taught to Héloïse the three languages necessary for the understanding of the Scriptures. The relation of master and pupil was not long preserved; a warmer sentiment than esteem seized their hearts, and the unlimited opportunities of intercourse which were afforded them by the canon, who confided in Abélard's age (he was now almost 40) and in his public character, were fatal to the peace of both. The condition of Héloïse was on the point of betraying their intimacy. They fled. Fulbert pursued, and Abélard having proposed marriage, the enraged uncle consented. On account of Abélard's ecclesiastical ambition, this marriage was to be kept secret; but Fulbert divulged the fact, which Héloïse, from a spirit of devotion to her lover, denied. Exasperated at his niece's perverseness, Fulbert punished her, and she then fled to Abélard, who placed her in the nunnery of Argenteuil. Fulbert now abandoned himself to a transport of savage vindictiveness, and, watching his opportunity, burst into Abélard's chamber with a band of ruffians, and gratified his revenge by inflicting on him an atrocious mutilation. Fulbert was deprived of his benefice, his goods were confiscated, and his accomplices punished by undergoing the treatment they had inflicted on Abélard. In this affair, Abélard, in his memoirs, admits his own excessive culpability; he states that he was under evil influence, that he abused the confiding trust of his friend Fulbert, and that he deliberately plotted the seduction of Héloïse, who, on her part, was far less blamable than he. The unhappy man, on his recovery from the outrage, sought an asylum in the monastery of St. Denis, and became a monk. Héloïse took the veil at Argenteuil. But Abélard's spirit was not crushed; he continued his public lectures. His great popularity soon drew a crowd of eager students from all parts, and this roused the malice of his old opponents. He abandoned the field of profane philosophy, and addressed himself to theology. His writings on the Trinity, maintaining doctrines to which some of the tenets of the modern Unitarians bear a close resemblance, were made the point of attack. In 1121 he was accused of heresy, and

a council being called at Soissons, in which he was not allowed to defend his doctrines, his works were adjudged heretical, and ordered to be burned. The monks of St. Denis, who were desirous of relieving themselves of a brother whose strict life was a rebuke to their own, now took offence at his opinion that Dionysius the Areopagite was not the founder of their abbey. For this impiety they followed him up so fiercely that he was compelled to flee, and in a desert place between Nogent and Troyes he built himself a rude hermitage, after the fashion of an anchorite. Many of his pupils followed him into this retreat, and with their assistance he founded the Paraclete. He was now elected abbot of the monastery of St. Gildas de Ruys, in the see of Vannes, but this was a source of further trouble. The feudal lord of the monastery had deprived the monks of their territory for their irregular life, which Abélard himself was no less desirous of reforming, and thereby ran the risk of assassination within the walls, while, in his desire to maintain the temporal rights of the convent, he was in little less danger without. He regretted the seclusion and independence of the Paraclete. Héloïse had been elected abbess of Argenteuil. The demesne of the convent had been claimed by the monks of St. Denis, and the nunnery suppressed. Héloïse and her nuns were without home or shelter. In this emergency Abélard offered them the Paraclete to found an institution, and went to assist personally in their establishment there, which was confirmed by a bull of Innocent II. This reunion, after a separation of eleven years, was precious to both; and he afterward made frequent visits to the Paraclete. His doctrines once more brought persecution upon him. This time St. Bernard was his opponent. Abélard was charged with dogmatizing on the power and nature of the divine essence, thereby attempting to reduce to human comprehension that which Bernard affirmed was, and ought to be, held incomprehensible by all Christians. In 1140 a council was held at Sens, in which Louis VII. in person presided. Abélard's opinions were again adjudged heretical, and he was sentenced to perpetual silence. To escape this decree, he appealed to the pope and set out for Rome, and on his road thither he was able to interest Peter the Venerable, abbot of Cluny, in his case. This friend used his efforts on his behalf, and procured an absolution from the holy father. Abélard died at St. Marcel, near Châlon, whither he had gone from Cluny for his health. His body was delivered to Héloïse, and by her interred at the Paraclete, where she herself was afterward buried by his side. In 1792 the Paraclete was sold, and the remains of the two lovers were removed to the church of Nogent-sur-Seine. They were exhumed in 1800 and placed in the garden of the Musée Français in Paris, and in 1817 were deposited beneath a mausoleum in the cemetery of Père la Chaise.—The position

of Abélard in the philosophical movement of his age is well described by M. Cousin: "A hero of romance within the church, a refined spirit in a barbarous age, a founder of a school, and almost a martyr to an opinion, everything conspired to make Abélard an extraordinary personage. But of all his titles, that which gives him a separate place in the history of the human mind is his invention of a new philosophical system, and his application of this system and of philosophy in general to theology. Doubtless before Abélard might be found some rare examples of this dangerous process, although a useful one, even in its errors, to the progress of reason; but it is Abélard who established it as a principle; who contributed more than any other to found scholasticism, for scholasticism is nothing else. After Charlemagne, and even before, there was taught in several places a little of grammar and logic; religious instruction, too, was not wanting, but this instruction was limited to a more or less regular exposition of sacred dogmas; it might suffice for faith, but did not nurture intelligence. The introduction of dialectics into theology could alone produce that spirit of controversy which is the vice and the honor of scholasticism. Abélard is the chief author of this introduction; he is, then, the principal founder of the mediæval philosophy, so that France has not only given to Europe, through Abélard, the scholasticism of the 12th century, but also at the beginning of the 17th century has given, in Descartes, the destroyer of this same scholasticism, and the father of modern philosophy. And there is no inconsistency in this; for the same spirit which had raised the ordinary religious instruction to that systematic and rational form which we call scholasticism, would alone be able to rise above that form, and to produce philosophy properly so called. Thus the same country was able to support, with an interval of a few centuries, Abélard and Descartes. We discover also, through the many differences of these two men, some striking resemblances. Abélard sought to give an account of the only thing which could be studied in his time—theology; Descartes has given account of what it was permitted to study in his time—man and nature. The latter recognized no authority but that of reason; the former undertook to introduce reason into authority. Both doubt, both investigate; they seek to understand all that is possible to man, and to rest only in certainty. This is their spirit in common, which they borrow from the French spirit, and this fundamental feature of resemblance causes many others; as, for example, that clearness of language which springs spontaneously from definite and precise ideas. It may be added that Abélard and Descartes are not only both Frenchmen, but that they belong to the same province, to that Brittany whose inhabitants are distinguished by so lively a sense of independence and so strong a personality. Thence,

in these two illustrious compatriots, with their native originality, with dispositions to admire moderately what was done before their time and in their time, came the love of independence, pushed often into a quarrelsome spirit; confidence in their own strength and contempt of their adversaries; more of logical connection than of solidity in their opinions; more sagacity than comprehensiveness; more of vigor in the temper of their mind and character than of elevation and profoundness in their thought; more of ingenuity than of common sense, satisfied with the perfection of their own views rather than rising to universal reason."—The works of Abélard were collected by François Amboise and André Duchesne, and first published at Paris in 1616. The best edition of his works is that of Cousin (Paris, 1850), who has accompanied the principal writings of the author with admirable critical and expository notices. The narrative of his life is contained in his autobiography entitled *Historia Calamitatum suarum*. Pope has versified some of the supposed letters between the lovers. The most important modern works on the biography of Abélard are by Fessler, *Abälard und Heloise* (2 vols., Berlin, 1806); Mme. Guizot, *Essai sur la vie et les écrits d'Abailard et d'Héloïse* (Paris, 1839); Rémusat, *Abélard* (2 vols., Paris, 1845); Böhringer, *Kirchengeschichte* (vol. iv., 1854); Wilkens, *Peter Abälard* (Göttingen, 1855).

ABELITES, **Abelians**, **Abelonians**, or **Abelonites**, a sect of Christians, probably of Gnostic origin, who, though practising marriage, denounced sexual intercourse as a service of Satan, maintaining that thereby original sin was perpetuated. As Abel had not been married, they took their name from him. Their numbers were recruited by children whom they brought up in pairs of each sex under one roof. They existed about the 4th century, and are mentioned by St. Augustine. They lived near the city of Hippo in Africa.—The name **ABELITES** was given in the 18th century to the members of a secret society, whose professed object was to cultivate the honesty and candor of Abel, whom they took for their model and patron.

ABEN, **Aven**, **Ebn**, **Ibn**, Arabic patronymic prefixes to proper names, corresponding to the Hebrew *ben*, son of. (See **BEN**.)

ABENAQUIS, or **Abnakis** (Men of the Eastern Land), a group of Indian tribes of the Algonquin family, originally occupying the present state of Maine, and comprising the Camibas or Abenaquis proper on the Kennebec, the Etechemins or Malecites as far as the river St. John, and, according to some, the Pennacooks on the Merrimack and the Sokokis west to the Connecticut. They were approached early in the 17th century by the English and French, but adhered to the latter, whose missionaries converted most of them to Christianity. They figure constantly in the New England border wars under the name of Tarranseens, but were finally overthrown and their missionary Rale

killed at Norridgewock in 1724. Many had emigrated to Canada, where two villages still remain, bearing the name Abenakis, at St. Francis and Beaucour. The remnants in Maine are called Penobscots and Passamaquoddies, from the rivers on which they reside. Another remnant is in New Brunswick, near Fredericton. During the American revolution they embraced the cause of the colonies under their chief Orono. Their language was thoroughly studied by Father Sebastian Rale, whose dictionary is still highly important. Their history has been written by the Rev. E. Vetroville (New York, 1866), and more fully by the Rev. J. A. Maurault (Sorel, 1866).

ABENCERRAGES (Arabic, *Ibn Serraj* or *Zerragh*), the name of a distinguished Moorish family, whose mortal feud with the Zegriss, another noble family of Granada, contributed to the fall of the Granadian monarchy. The quarrel originated in the varying fortunes of Mohammed VII. of Granada, in the earlier part of the 15th century, who was alternately a monarch and an exile, and whose cause the Abencerrages espoused with unswerving fidelity. It is told that one of the youths of the Abencerrages, having loved a lady of the royal house, was climbing to her window when he was discovered and betrayed, and the king, in revenge for the outrage on the sanctity of his harem, shut up the whole family in a tower or court of the Alhambra, and, letting loose the fury of their hereditary enemies, had them butchered in cold blood. This tragical tale has been the foundation of many poetical productions. The inexorable criticism of our century has, however, demonstrated the fictitious character of the romantic story. (See *Conde's Historia de la dominacion de los Arabes en España*, Madrid, 1829.)

ABENDBERG, one of the secondary elevations of the Bernese Alps, rising from the plateau of Interlachen or Bernese Oberland, in the canton of Bern, Switzerland, S. W. of the village of Interlachen, its northern base abutting on the lake of Thun. It rises about 3,500 feet above the plateau, and 5,300 above the sea level. Its southern slope is very fertile, and the lower portion heavily wooded. It is regarded as one of the most salubrious regions of the Alps. In 1842 Dr. Lou's Guggenbühl selected a site on the southern slope, several hundred feet below the summit, for an asylum for cretins, whom he hoped by careful treatment and the health-giving influences of the climate to restore to reason and healthful development. The institution did not accomplish all that was expected from it, and, after being maintained for 18 or 20 years, was on the death of its founder given up. (See *GUGGENBÜHL, LOUIS*.)

ABEN EZRA, properly *Abraham ben Meir ben Ezra*, one of the most esteemed biblical commentators among the Jews of the 12th century, born in Toledo, Spain, in 1093, died in Rome in 1167 or 1168. He was also distinguished as

a physician, mathematician, astronomer, poet, and grammarian. He was poor, and travelled extensively, lecturing before large audiences. His writings, some of which have been translated into Latin, are numerous, and evince originality, boldness, and independence. His style is pithy and often epigrammatic.

ABENSBERG, a small town of Lower Bavaria, 18 m. S. W. of Ratisbon; pop. about 1,600. It is believed to have been the Abasinum of the Romans. It has a thermal spring, and contains the ruins of a fine castle. On April 20, 1809, Napoleon fought and defeated the Austrians near Abensberg, who lost 12 guns and 20,000 men, including the prisoners made on the following day. This was the precursor of the victories of Landshut and Eckmühl.

ABERBROTHWICK. See *ABERROATH*.

ABERCROMBIE, James, a British general, born in Scotland in 1706, died April 28, 1781. He was commander-in-chief in America in 1756, and again in 1758, on the retirement of Loudoun. He attacked Ticonderoga July 8, at the head of 15,000 men, and was repulsed with a loss of nearly 2,000 killed and wounded. He then retreated to his fortified camp on the south side of Lake George. He was superseded by Sir Jeffery Amherst, who retook Ticonderoga and Crown Point. In 1759 he returned to England, and was afterward a member of parliament and deputy governor of Stirling castle.

ABERCROMBIE, John, M. D., a Scottish physician, born in Aberdeen, Nov. 11, 1781, died in Edinburgh, Nov. 14, 1844. He contributed valuable papers to the "Edinburgh Medical and Surgical Journal." His principal works are: "Pathological and Practical Researches on Diseases of the Brain and Spinal Cord" (Edinburgh, 1828, 1830); "Inquiries concerning the Intellectual Powers of Man and the Investigation of Truth" (1830); "Philosophy of the Moral Feelings" (1833). The university of Oxford conferred on him the honorary degree of doctor of medicine, and in 1835 Marischal college elected him its lord rector. He was considered the first physician in Scotland.

ABERCROMBY, Sir Ralph, a British general, born in 1738, died March 28, 1801. He was descended from a good Scottish family, entered the army, and became major general in 1787. In 1793 he went to Holland in the unsuccessful Walcheren expedition, and gained universal esteem by his humanity and soldierlike qualities. He was now made commander-in-chief in the West Indies, and took several of the French West India islands. After his recall he was made lieutenant governor of the Isle of Wight, and showed his judgment and presence of mind in suppressing a mutiny of the Highland regiments, who had revolted because they were required to serve as marines. On the breaking out of the rebellion of 1798 in Ireland, he was sent there as commander-in-chief, but his distaste for the service was so decided that he was removed to Scotland. In 1799 he again served in Holland. In 1800 he

was sent to Egypt to act against the French invasion of that country, and on March 8, 1801, he made good his landing at Aboukir in the face of a hostile force, but with considerable loss. He encamped near Alexandria, and was attacked by the French, and on the 21st the battle of Alexandria was fought. Sir Ralph was severely wounded early in the action, but concealing his wound, he continued on the field, giving his orders, until after the action was over, and the French had been entirely defeated. His dangerous condition was then made known. He died a week afterward, and his remains were conveyed to Malta and there interred. His widow was created a peeress as Baroness Abercromby, with succession.

ABERDARE, a town and parish of Glamorganshire, S. Wales, at the junction of the river Dare with the Cynon, 20 m. N. N. W. of Car-

diff, and 4 m. S. W. of Merthyr Tydvil; pop. of the parish (25 sq. m.) in 1861, 32,299; in 1871, about 40,000. In 1841 the population was but 6,471. The increase is due to the great extension of coal and iron mining. The coal is largely consumed in the iron mills of the town, and a considerable amount is exported. There are many fine public and private buildings, good water works, and a public park.

ABERDEEN. **I. New,** the capital of the county of Aberdeen, Scotland, situated between the rivers Don and Dee, and near the mouth of the latter, 512 m. from London, and 114 m. N. by E. from Edinburgh; pop. in 1871, 88,125. It was styled New Aberdeen after its restoration in 1336, having been burned by Edward III. It is incorporated by royal charter granted by William the Lion in 1179. The public edifices, chiefly of granite, are the East and

Aberdeen from the Cross.

West church, the Marischal college, the royal infirmary, the town house and tolbooth or jail, the post office, mechanics' hall, and several others erected within the last few years. There is a fine one-arch bridge of 132 feet span over the river Dee, opening into Union street, which is 70 feet wide and a mile long, and is the chief thoroughfare of the city. Over the Don, at the N. end of the town, is a bridge of five arches and 75 feet span. There are about 50 religious edifices of all denominations, the largest number being Presbyterian. The East and West church is a noble pile 170 feet long, with a spire 150 feet high. The town house and tolbooth are situated in Castle street, and have a spire 120 feet high. Marischal college, founded by George Keith, earl of Marischal, in 1593, has an observatory and good collection of instruments, a museum, and a fine library. Since 1858 it has been incorporated

with King's college as the university of Aberdeen, which has now 21 professors and over 600 students. Gordon's hospital, founded in 1729 by Robert Gordon, is a school for boys, who are admitted from 8 to 11, and kept until 15 years of age, and on quitting the foundation are entitled to receive an apprentice fee of £10 or £7. The other charitable institutions are the royal infirmary and lunatic asylum, the general dispensary, two ophthalmic institutions, the Cruickshank asylum for the blind, Dr. Carnegie's hospital for destitute female children, the Midbellie fund for granting pensions of £5 to £15 to widows, and the female orphan asylum, which is supported by voluntary contributions, and whose inmates are trained for domestic service. The cross on the east of Castle street is a monumental structure of remarkable beauty. The market is commodious, built in two floors, with galleries

running around the whole. The commerce and manufactures of Aberdeen are extensive. Ships of 1,000 to 1,500 tons are built here. Cotton manufactures employ 4,000 hands, linens and woollens each as many more. The Aberdeen granite is used all over Great Britain, and largely exported. Aberdeen is actively engaged in the northern whale fishery. The Victoria dock has a water area of 40 acres. There are water works which supply the town from the river Dee. There is railway communication direct with London. The town is governed by a provost, four bailies, a dean of guild, and a treasurer, with 12 other members of council. **II. Old**, a town of great antiquity, situated one mile N. of the new town, near the mouth of the Don; pop. about 2,000. King's college, founded in 1494, is situated here.

ABERDEEN, Earls of, viscounts of Formartin and barons of Haddo, Methlie, Tarvis, and Kellie in the Scottish peerage, and Viscounts Gordon in that of the United Kingdom. The family is an offshoot of the ancient Scotch family of the Gordons.—**SIR JOHN GORDON** of Haddo was created a baronet in 1642 by Charles I., as a reward for his services in the battle of Turriff between that monarch and the parliamentary forces. Being taken prisoner after a desperate defence of the house of Kellie, he was long imprisoned in the nave of the ancient cathedral of St. Giles at Edinburgh, which from him took the familiar name of "Haddo's Hole," and was at length beheaded in 1645. His estates remained under sequestration till the restoration of Charles II., when they were restored to his eldest son, Sir John Gordon, who died in 1665.—**SIR GEORGE GORDON** of Haddo, lord high chancellor of Scotland, was in 1682 elevated to the Scottish peerage, by the titles above mentioned. On the revolution the new earl resigned office, and declined taking the oaths of allegiance to William of Orange, but he appeared again at court in the reign of Queen Anne. He opposed the union of Scotland and England from his seat in parliament, and died in 1720, aged 83.—**GEORGE HAMILTON GORDON**, 4th earl, born in Edinburgh, Jan. 28, 1784, died Dec. 14, 1860. He was educated at Harrow, and at St. John's college, Cambridge, where he graduated in 1804. While still a young man he founded a club, the members of which must have made a journey to Greece. In 1806, though only 22, he was elected as one of the 16 Scottish representative peers, and so remained until he was created a peer of the realm in his own right in 1814, as Viscount Gordon of Aberdeen. In 1813 he was sent to the court of Vienna as a secret envoy to detach Austria from her enforced alliance with Napoleon. He succeeded, and was soon afterward again sent to Vienna, and arranged the preliminaries between the emperor Francis and Joachim Murat, king of Naples, for the restoration of the Bourbons to the throne of Naples. During Canning's ministry he was in

opposition. In 1828, the duke of Wellington having formed a ministry on high tory principles, Aberdeen became secretary of state for foreign affairs, remaining in office till November, 1830, and opposing the Greek war of independence, but favoring the abolition of the test and corporation acts, and the Catholic emancipation act, while resisting the movement for parliamentary reform. On the death of George IV. Aberdeen resigned with his colleagues. He afterward took a conspicuous part in endeavoring to reunite the Scottish national church. From 1841 to 1846 he was again secretary for foreign affairs, in the ministry of Sir Robert Peel, and participated in settling the northeastern and Oregon boundary questions with the United States. On Dec. 28, 1852, he became prime minister, but was compromised in public opinion by his attempt to evade the Crimean war, and by its blunders after it was begun, and was compelled to resign Oct. 7, 1855, when he was made a knight of the Garter. He had been president of the society of antiquaries, and in 1822 published "An Inquiry into the Principles of Beauty in Grecian Architecture."—**GEORGE HAMILTON GORDON**, 6th earl, born Dec. 10, 1841, lost at sea Jan. 27, 1870. He succeeded to the title in 1864. In 1866 he embarked in a sailing vessel from Aberdeen for St. Johns, N. B., and during the voyage volunteered to fill the place of a disabled seaman. This occupation he resumed after some time spent in travel, made several short voyages under the name of George Henry Osborne, acted as a commercial agent at Pensacola, and was licensed as a mate in New York in 1867, and as a captain in 1868. In January, 1870, he shipped as mate of the three-masted schooner Hera, bound from Boston to Melbourne, and on the fourth day out was swept overboard in a storm. He had for some time kept his family advised of his wanderings, but as all replies to his letters miscarried, he ceased writing. An agent sent out in search of him succeeded with great difficulty in tracing his subsequent career.

ABERDEENSHIRE, a county of Scotland, on the N. E. coast, between lat. 56° 52' and 57° 42' N., and lon. 1° 49' and 3° 48' W.; length, 87 m.; greatest breadth, 36 m.; area, 1,985 sq. m., or 1,270,740 acres, being about one sixteenth of all Scotland; pop. in 1871, 244,607. It contains 83 parishes and parts of six others, and is divided into the districts of Mar, Formartin, Buchan, Garioch, and Strathbogie. On the S. and S. W. borders of the county are the Grampian hills. The Highlands of this district include some of the highest mountains in Scotland, Ben Macdui, Cairntoul, Ben Avon, and Cairngorm, from which last the fine yellow pebble so much used in Highland dress and ornaments takes its name. The Scottish kings used to hold formidable gatherings to hunt the red deer in the wilds of Braemar; and the abundance of carefully preserved game makes the district still a

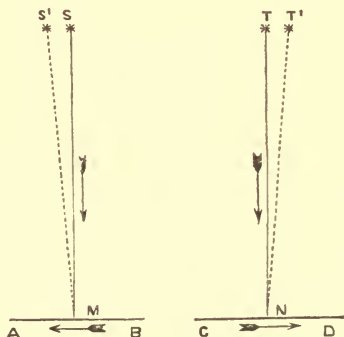

favorite rendezvous of sportsmen. The Bullers of Buchan, near Peterhead, are also an attractive object to the tourist. The chief rivers are the Dee and the Don. The climate, except in the mountain districts, is mild, and wheat prospers. Cattle, sheep, pigs, eggs, and butter are transported by steam from Aberdeen to London, to the value of about £1,000,000 annually. Granite is the most important mineral production. Besides the queen's estate of Balmoral, Aboyne castle, belonging to the earl of Aboyne, Haddo house, seat of the earl of Aberdeen, Huntly lodge, of the duke of Richmond, and Forbes castle are noteworthy.

ABERDEVINE (*carduelis spinus*), also called the siskin, a small European song bird, which breeds in the north of Europe, and visits England, France, and Germany during the winter season only. It somewhat resembles the green variety of the canary bird, with which it is so far connected that it will interbreed with it in confinement, when the produce is what are known by bird fanciers as mules. Its length is about $4\frac{3}{4}$ inches, its tail short and forked. Its upper parts are variegated with olive brown, yellow, and pale green, the feathers being edged with yellow; its bill and legs are light horn brown. Its note is soft and pleasant. It builds in the topmost branches of pine trees, and lays four or five bluish white eggs, speckled with purplish red. Its Latin name *carduelis* expresses its fondness for the seeds of the thistle.

ABERNETHY, John, an English surgeon, born either in Scotland or Ireland in 1764, died at Enfield, April 18, 1831. He was a pupil of Sir Charles Blick, surgeon to St. Bartholomew's hospital, London, and afterward of the celebrated John Hunter. Early in his career, in a work entitled "The Constitutional Origin and Treatment of Local Diseases," he established the fundamental principles upon which surgical operations have since been conducted. His bold and successful operations of tying the carotid and external iliac arteries established his reputation, and almost revolutionized surgery. He acquired great distinction as an anatomist and physiologist, succeeded Sir Charles Blick at St. Bartholomew's, was appointed surgeon to Christ's hospital in 1813, and in 1814 professor of anatomy and surgery to the royal college of surgeons. His works became text books in nearly all the medical colleges in Europe and America. He contributed the anatomical and physiological articles to Dr. Rees's "Cyclopædia" from A to C, and published numerous tracts, treatises, and surgical and physiological essays. One of the most popular and well known of his works was his "Surgical Observations," the perusal of which he almost invariably recommended to his patients. His last production (issued a few months prior to his death) was a collected and revised edition of his "Lectures on the Theory and Practice of Surgery." His writings are remarkable for clearness, concise-

ness, and simplicity. His simple and impressive style of lecturing never failed to enchain his audience, despite his dogmatism and contempt of others' opinions. His private character was admirable, but in public his manners were uncouth, churlish, and capricious. Many anecdotes of his eccentricities are current.

ABERRATION. I. Aberration of Light, the alteration of apparent position in a heavenly body, due to the fact that the observer is carried along by the earth's motion, the velocity of which is a measurable quantity in relation to the velocity of light. The aberration of light is therefore due to the combined effect of the transmission of light and of the earth's motion. The solution of all problems to which it gives rise is due to the astronomers of the last century; their calculations are in perfect accord with the minutest practical observations, made with the most elaborate and largest astronomical instruments constructed in some observatories chiefly for the purpose of measuring this amount of aberration. If, at a time when rain drops were falling in a perfect calm perpendicular to the earth's surface, we were standing on a platform car on a railroad track, and rapidly moving forward or backward, the drops would strike us under an angle deviating from the perpendicular in proportion to the swiftness of our motion. The direction of this deviation would in either case be toward the side we are moving to, and this is exactly the case with the light coming to us from the heavenly bodies. This is evident when we compare the direction of the rain drops with that of the light, and that of the car with the motion of the earth in its yearly orbit. If now the direction in which light reaches us be changed, the apparent position of the body from which the light proceeds must be changed also. Let A B

Aberration of Light.

represent a small portion of the earth's orbit, and S M the ray of light from a fixed star S; the motion of the earth from B toward A will cause the light to come in the direction S' A, and the star will appear to stand in S'. If CD represents a small portion of the earth's orbit half a year later, thus moving in an opposite direction, the star T will for the same rea-

son appear to stand in T'. If the velocity of our earth was so much slower as to be for our most delicate instruments incomparable to the velocity of light, no apparent influence would be exerted on the apparent direction, and there would be no appreciable aberration; but the relation happens to be within the pale of actual measurement. Taking the length of the earth's yearly orbit in round numbers at 600,000,000 miles and the length of the year at 31,556,931 seconds, the velocity of our earth is nearly 19.2 miles per second; and light being transmitted at the rate of 192,000 miles per second, it is clear that it travels about 10,000 times faster than the earth. If now we consider that an equal velocity would change the direction of the perpendicular, or 90°, into its half, or 45°, we see that a velocity of only $\frac{1}{10,000}$ would deviate the angle approximately $\frac{1}{10,000}$ of 45°, or about 16 seconds. This, however, is a rough estimate; trigonometrically calculated, we obtain more, namely, 20 seconds. This now must be the maximum aberration produced by the yearly motion of the earth on the position of all stars observed at right angles to the direction of that motion. They must all appear displaced to an amount of 20" forward, and this is in fact observed in all heavenly bodies at right angles to the plane of the ecliptic. As after six months the earth moves in an opposite direction at the other side of the sun, this displacement must be observed in an opposite direction after the lapse of every half year, making a total displacement of 40" in the position of all the stars situated near the poles of the ecliptic; therefore they appear to have a yearly movement in small ellipses of 40" mean diameter, or about one fortieth the diameter of the moon. **II. Aberration in Optical Instruments.** As white light is composed of colored rays of different refrangibility, any kind of refraction must split it up into rays of different colors. This is called dispersion. As the convex lenses used in telescopes, microscopes, and other optical instruments refract the light to focal points, this dispersion causes an infinite number of foci. Those consisting of the most refrangible rays, the violet, are the nearest to the lens, and they follow in the order of their refrangibility—blue, green, yellow, orange, and red; the focus of the last is the furthest distant from the lens. This grand defect, called chromatic aberration, is corrected by the construction of achromatic lenses.

Chromatic Aberration.

(See ACHROMATIC LENS.) The course of the rays producing chromatic aberration is repre-

sented in the adjoined figure, in which A B is the lens, V the focus of the most refrangible or violet, and R that of the least refrangible or red rays.—Another defect, called spherical aberration, arises from the nature of the curve used in making lenses and reflectors. Geometry proves that parallel rays can only be refracted and reflected to a single focus by a parabolic curve; however, lenses and reflectors are ordinarily ground as parts of a sphere, which differs from a parabola in the fact that in the latter the amount of curvature increases toward the centre or axis. The consequence is that a section of a sphere, not having curvature enough toward this point, has an infinite number of foci at different distances; those formed by parts nearest to the axis will be the furthest off, while those formed by the refractions or reflections near the circumference of the lens or mirror will be the nearest. The two figures

Spherical Aberration.

given here represent the case of this aberration by refraction and reflection: C D is the lens, of which the rays passing near the centre P are united in F, while the rays passing near the circumference D C unite nearer to the lens in E. G H is the curved mirror or reflector which reflects the rays U I and W K falling on it near its centre in N, while the rays S G and T H, falling on it near the circumference, are brought together much nearer in M. When the aperture of the lens or mirror is small, for instance only 5° or about $\frac{1}{10}$ part of the circumference, these differences are practically inappreciable; but when the aperture must be large, as is the case with astronomical telescopes, peculiar arrangements are contrived, so that in making the lenses or reflectors a curve is obtained as nearly as possible of the parabolic form.

ABERYSTWITH, a seaport town of Cardiganshire, Wales, near the outlet of the Ystwith and Rheidol, 39 m. N. E. of Cardigan; pop. in 1871, 6,896. It is a bathing place, and has considerable commerce and extensive fisheries. In the vicinity are many lead mines.

ABEYANCE (law Fr. *abbayer*, to expect, wait for; Fr. *bayer*, to gape), a law term implying expectation, suspense, though by the signification preferred by the best authors the thing in abeyance is conceived to be in the remembrance or consideration of the law. The title to a ship captured in war is said to

be in abeyance until condemnation to the captor by the prize court. So an estate of inheritance or the fee was said to be in abeyance when there was no one in being in whom it could vest, as in the case of a grant to A for life, remainder in fee to the heirs of B, who was then living: as there can be no heir of a living man, the fee was said to be in abeyance until B's death. Mr. Fearn, an acute writer upon the law of real property, denounced the theory of an abeyance as an absurd fiction; and he contended with great ability that in the case just supposed the estate of inheritance was not in abeyance during B's life, but remained in the grantor of the life estate until the happening of the condition on which it might pass to B's heirs divested him of it. The principle of abeyance, however, has always stood fast in the law, and has carried with it very practical results. The plan of the feudal system, which required that there should always be some one ready to render the military and other feudal services to the lord, fixed the rule of the feudal, and later of the common law, that there must always be a tenant of the freehold, and that that must never be in abeyance. It was difficult for a long time, however, to get rid of the abeyance of the fee, that is, of the absolute ownership of the estate, distinguished from mere portions of it like a freehold life estate. But the recognition of the rule caused great embarrassments; for during the suspension of the fee there was no one to defend the title, or take any of those remedies in respect to the property which depended on the absolute ownership. The doctrine, therefore, came to be regarded with more and more disfavor, and its inconveniences inspired from time to time some of the most important reforms of the law. Blackstone says in one of his arguments, that the famous rule in Shelley's case owed its origin and adoption to the aversion of the common law to the suspension of estates through the operation of abeyance; and the same spirit of the law helped to break down the limitation or creation of remote and contingent remainders.

ABIAD, Bahr el. See NILE.

ABIATHAR, a Hebrew high priest, the son of Ahimelech, who was slain by Saul for receiving David when a fugitive. He was for a long time faithful to David, especially during Absalom's rebellion, when he accompanied the king. He afterward, however, took part in the rebellion of Adonijah, and was in consequence deprived of the priesthood and banished from the capital by Solomon.

ABIB (properly, *Hodesh haabib*, the month of the ears of corn), the first month of the Mosaic Hebrew year, corresponding nearly to our April. After the Babylonish captivity this month was called Nisan, month of blossoms or flowers. (See NISAN.)

ABICH, Wilhelm Hermann, a German-Russian naturalist, born in Berlin, Dec. 11, 1806. He graduated in 1831 at the university of Berlin,

visited Italy and Sicily, and published *Erläuternde Abbildungen von geologischen Erscheinungen, beobachtet am Vesuv und Actna 1833 und 1834* (Berlin, 1837), and *Ueber die Natur und den Zusammenhang der vulkanischen Bildungen* (Brunswick, 1841). In 1842 he became professor of mineralogy in the university of Dorpat, and in 1853 a member of the St. Petersburg academy of sciences. He has explored the mountain ranges of the Caucasus, Russian Armenia, northern Persia, and Daghestan, and published in the German and French languages many works relating to the palaeontology, geology, &c., of those regions, besides his contributions to the bulletins and memoirs of the St. Petersburg academy since 1843.

ABIMELECH. **I.** A Philistine king of Gerar, into whose dominions Abraham removed after the destruction of Sodom. The latter, from motives of prudence, pretended that Sarah, his wife, was his sister, whereupon Abimelech took her from him, intending to make her his concubine. By divine command, however, he restored her, rebuking Abraham for his fraud. Another Philistine king of Gerar of the same name was similarly deceived by Isaac in regard to Rebekah, and also rebuked him. **II.** A son of Gideon by a Shechemite concubine, who made himself king after murdering all his 70 brethren except Jotham, and was killed after a reign of three years while besieging the tower of Thebez. (See HEBREWS.)

ABINGER, James, Lord, an English lawyer, born in Jamaica about 1769, died in London, April 7, 1844. He is better known and remembered as Sir James Scarlett. He was a member of parliament for Peterborough from 1818 to 1830, afterward for Maldon, Colchester, and Norwich. He was at first a moderate whig, but gradually became a staunch Tory. As an advocate he was one of the most popular men of his day, and his practice was immensely lucrative. His oratorical powers were of the most persuasive character; his speech usually assumed almost a conversational tone with the jury, and he had the art of appearing to address himself to each of his auditors individually. He was attorney-general from April, 1827, to January, 1828, and again from May, 1829, to November, 1830. In December, 1834, he was appointed lord chief baron of the exchequer, and on Jan. 12, 1835, he was raised to the peerage as Baron Abinger.

ABINGTON, Frances, an English actress, born about 1731, died in London, March 4, 1815. Her father was a common soldier named Barton. She was employed as a child in running errands, and afterward as a flower girl. Her first appearance as an actress was on the boards of the Haymarket in the character of Miranda in "The Busybody," 1755. She had previously married Mr. Abington, her music master, from whom she separated in a few months. At Dublin she was a great favorite, and when Garrick in 1765 invited her to London, she soon became the first comic

actress of the day. She bade adieu to the stage April 12, 1799, and left at her death a legacy to each of the theatrical funds.

ABIPONES, a tribe of South American Indians who inhabited the district of Chaco in Paraguay, but now occupy the territory lying between Santa Fé and St. Jago, east of the Paraná river. Our accounts of this singular people are mainly derived from Dobrizhoffer, who lived among them seven years at the end of the last century. His volumes were translated from the Latin by Miss Coleridge (3 vols. 8vo, 1822). The whole tribe at that time did not number above 5,000. They practise tattooing. The men are of tall stature, good swimmers, and expert horsemen. The women practise infanticide to a great extent, but suckle those infants they permit to live for the space of two years. In counting they can go no further than three. See A. d'Orbigny, *L'Homme Américain*, vol. ii.

ABJURATION, Oath of, usually, an oath by which one renounces allegiance. But anciently in England, and before 21 James I., ch. 28, § 17, one who had been guilty of a felony, and who had fled for safety to the sanctuary of a church or churchyard, might upon confession of his crime take an oath before a coroner that he would abandon or renounce the country for ever, and thereupon he was permitted to leave it in safety. The statute just named took away the privilege of sanctuary, and with it this privilege of abjuration. Formerly too, in England—for example, under the statute of 35 Elizabeth, ch. 1—any person above the age of 16 years who refused to hear divine service or incited others to abstain from attending it, and by speech or in writing denied her majesty's authority in causes ecclesiastical, was required to conform and make submission to the church, or else to abjure the realm forthwith and for ever, before the justices at the assizes or in sessions.—The oath of abjuration in respect to the sovereign came into use in England after the restoration, and was changed from time to time until in the 6 George III. it took the form which it retained till 1858. All clergymen and public officers were required to take it on coming to their places, together with the separate oaths of allegiance and supremacy. The statute of 21 and 22 Victoria, ch. 48 (1858), displaced these three oaths by a single one which embraced the elements of all of them. It ended with the words, "and I make this declaration on the true faith of a Christian." In ordinary cases Jews had been excused from adding these words, but until 1858 no statute authorized their omission from the parliamentary oath; so that when in 1850 Baron de Rothschild, and in 1851 Mr. Salomons, had come into the house and refused to take the oath in its full form, they were declared incapable of sitting as members. The statute of 21 and 22 Victoria, ch. 49, however, authorized the houses to dispense with the obnoxious words in the case of Jews, and this au-

thority was thereupon exercised in favor of Baron de Rothschild; and in 1860 a standing order on the subject was made to avoid the inconvenience of special resolutions in separate instances. But the statute of 29 and 30 Victoria, ch. 19 (1866), removed all difficulty by dropping the embarrassing clause altogether from the parliamentary oath.—Under the United States statute relating to naturalization, the subject of a foreign state who seeks to become an American citizen is required to declare on oath or affirmation, before the court to which he applies, that he absolutely and for ever renounces and abjures all allegiance and fidelity to every foreign power, authority, or sovereignty whatever, and particularly, and by name, to the foreign prince or potentate, state, or sovereignty of which he has been hitherto a subject.

ABKHASIA, or *Abchasia*, the country of the Abkhasians, a warlike tribe between the Black sea and the Caucasus, which has been conquered by the Russians. It is bounded N. and N. E. by the land of the Circassians, E. by Suanethi, S. E. by Mingrelia, and S. and W. by the Black sea. Its area, vaguely limited, is about 10,000 sq. m. Under the Roman emperor Justinian the Abkhasians became Christians, but subsequently they adopted Mohammedanism, to which religion they still nominally belong, though their religion in fact consists of a barbarous mixture of Christian, Moslem, and heathen notions and usages. The country was formerly divided into ten communities, the most important of which were Abkhasia proper (with 80,000 inhabitants), the Tziebelda (8,000), Samurzakan (9,800), and the country of the Jigets or Zadzes (10,000). Abkhasia proper has again had since 1771 an hereditary dynasty of its own, that of the Shervashidze, which since 1824 has been under Russian sovereignty. The residence of the prince is at Soyuk-Su (pop. about 5,000). On the coast the Russians have fortified several places, the most important of which is Suklum Kaleh, or Baglata (pop. 300), supposed to be the site of the ancient Dioscurias, where according to Pliny 300 different tribes used to trade. About 15,000 Abkhasians have of late emigrated from Russia to Turkey.

ABLUTION, a religious ceremony in many portions of the world. In the Catholic church it means the cleansing of the eup after the Lord's supper, and is applied to the wine and water with which the priest who consecrates the host washes his hands.

ABNER, the son of Ner, cousin of Saul and the general of his troops. He was greatly loved by Saul, and faithful to him until his death, and then transferred his allegiance to Ishbosheth, Saul's son, to whom he preserved the throne of Israel for seven years against the rival claims of David. At length, Ishbosheth having accused him of improprieties with one of his father's concubines, he went over to the cause of David. But the aid he might have rendered to that king was cut off by his sudden

death at the hand of Joab, David's captain, who was probably moved with jealousy at the influence of so powerful a rival for the king's favor, though Joab alleged that the object of the assassination was to avenge the death of his brother Asahel. David was, or, as intimated by Josephus, pretended to be, deeply afflicted at the death of Abner, and lamented him in a sort of funeral dirge.

ABO (Swed. *Åbo*), a city of Russia, in Finland, capital of the government of Abo-Björneborg, built on both sides of the Aurajoki, not far from where it flows into the gulf of Bothnia, 260 m. W. by N. of St. Petersburg; pop. in 1870, 21,830. It was founded in 1157 by the Swedes, and was the capital of Finland till 1819. A bishopric was established here in the 13th century. In 1827 the greater part of the city was destroyed by fire, including the university buildings and the library, containing 40,000 volumes. The university was rebuilt in Helsingfors, the new capital of the province. Abo is still the seat of considerable trade.—The peace of Abo, concluded Aug. 17, 1743, between Sweden and Russia, terminated the struggle between those countries commenced in 1741, at the instigation of France, in order to prevent Russia's participation in the war of the Austrian succession. During this contest, the blunders of the Swedish generals enabled the Russians to take possession of Finland. The empress Elizabeth offered to restore the greater part of the province, on condition that Sweden should elect Prince Adolphus Frederick of Holstein-Eutin successor to the throne. This demand Sweden complied with July 4, 1743.

ABO-BJÖRNEBORG, one of the governments of the grand duchy of Finland, situated on the Finnish and Bothnian gulfs; area, 9,869 sq. m.; pop. in 1867, 319,784, nearly all Lutherans. Capital, Abo.

ABOMEY, the capital of the kingdom of Dahomey, Africa, in lat. 7° 59' N., lon. 1° 20' E., 100 m. N. N. W. of Badagry; pop. about 50,000. It is about eight miles in circumference, surrounded by a ditch, and entered by six gates, all of which are ornamented with human skulls. It contains three royal palaces of two stories each. Within the palaces are barracks, in which the 5,000 Amazons of the king's army live in celibacy, guarded by eunuchs.

ABORIGINES. See AMERICAN INDIANS.

ABORTION (Lat. *abortus*, a miscarriage), the premature expulsion of the fetus or embryo, at so early a period that it is incapable of living, and the pregnancy is consequently unfruitful. In the human species, a child may often continue to live and be reared if born as early as the seventh month of pregnancy; and these accordingly are said to be cases of "premature birth." Nevertheless, if a child born after the seventh month and before the natural term of parturition should at once die in consequence of such premature birth, this would also be a case of abortion. In the earlier and

middle periods of pregnancy, the death of the fetus sometimes takes place from internal causes, and it is soon afterward discharged from the uterus, to which it has become a source of irritation. Thus, whether the fetus die in consequence of premature delivery, or whether the premature delivery be a consequence of the death of the fetus, all such cases are generally included under the term abortion. Abortion is sometimes produced, by various means, with the criminal intent of getting rid of the product of conception, and thus preventing the birth of a living child. All such means are dangerous to the mother, and may readily lead to a fatal result. The production of abortion for this purpose is therefore doubly criminal, since its first object is the destruction of the life of the fetus or child; and this object is furthermore accomplished at the risk of death to the mother.—The legal and medical sciences are not quite in accord upon the matter. The increasing frequency of this practice of abortion in the most enlightened communities at the present day has attracted to it the particular attention of physicians; and they urge that the evil cannot be suppressed without the enactment of laws not only more severe but of a different character from those which have hitherto existed. They insist that, as the first and most essential step in the course of a reform of the law, the legislature must not only abandon the old idea that the quickening of the child is the commencement of its life, but must proceed directly upon the fact, especially emphasized by modern medical science, that the life of the future human being begins at the very instant of conception; that not only therefore must the old criteria of criminality which depended upon quickening be abandoned, but the protection of the fetal life must be the direct object of the law, no less than the protection of the life or well-being of the mother, or the general conservation of public morality and decency. It will be seen on an examination of the later statutes that a substantial advance toward these positions has been made by legislation during the last 20 years.—For the purpose of an intelligent view of the existing law, and in anticipation of still further legislation, some facts upon the physical side of the subject may be well kept in mind. The fetus cannot be properly regarded at any period of its existence as merely *pars viscerum matris*, as the phrase is; that is to say, as an essential constituent part of the mother. The ovum does not originate in the uterus, but after impregnation is lodged there, being totally disconnected from the organism of the mother during the transition; and it is attached to the uterus for the simple purposes of shelter and nutrition. The human form is developed and is visible in the fetus even before the period of its quickening. This term quickening is the name given to those phenomena of different sorts by which action in the fetus is manifested to the mother.

This mere incident of progressive development appears at no absolutely certain time, but usually between the 115th and 130th days after conception. Viability of the fœtus does not depend necessarily on its age, though it is usually not viable, or capable of living, before the lapse of seven months after conception; yet it may be at undeterminable periods before that time.— Though the legal offences relating to abortion depend almost entirely upon positive statutes, yet it is sometimes material to determine whether an act of this character is criminal at common law, as the phrase is; or, in other words, by the general, customary, and unwritten law. It is said by some of the best writers that there can be no doubt that at common law the wrongful destruction of an unborn child was a high misdemeanor, and that at an early period in England it was deemed murder. There are no reported cases confirming this view, but two passages of Bracton and Fleta ought not to be overlooked. Though they are in some respects of obscure meaning, yet they are noteworthy, not only as being the earliest declarations on the subject contained in English law books, but because the rules they lay down are so far advanced beyond those of the English law even of to-day. Both books were written in Latin, the former in the reign of Henry III. (1216–1272), the latter in that of Edward I. (1272–1307). Bracton says: “If any one shall have given blows or drugs to a pregnant woman, in consequence of which she shall have aborted, if the child were already formed and animate, and especially if animate, he is guilty of homicide.” The author of Fleta says: “Whoever shall have done violence to a pregnant woman, or shall have given her drugs or blows so as to produce an abortion, or to prevent conception (*ut non concipiat*), if the fœtus was already formed and animate, is a homicide; and likewise, whoever shall have given or taken drugs with the intent to prevent generation or conception (*conceptionis*). So, too, the woman is guilty of a homicide who has destroyed her animate child in her womb, by potions or things of that sort.” These passages, it will be noticed, pronounce the mother’s destruction of her unborn quick child a homicide. The present law of England declares that any woman being with child, and whether quick or not is indifferent, who uses drugs or any other means to procure her miscarriage, is guilty of a felony, and is punishable by imprisonment only. Coke, who lived in the 16th century, says in his third Institute that “if a woman be quick with child, and by a potion or otherwise killeth it in her womb, or if a man beat her whereby the child dieth in her body and she is delivered of a dead child, this is a great misprison and no murder.” In this passage occurs the reference to the quickening of the child, which has always down to a very recent period been made an essential element in the degree of criminality in English acts relating to abortion. With

reference to the common law on the subject, it has been held in Massachusetts, Maine, and New Jersey, that it is not, apart from statutes, an indictable offence to use means upon a pregnant woman, with her consent, for the purpose and with the effect of procuring an abortion, unless the mother were quick with child. It is not to be understood, however, from this that very grave and even capital offences may not be involved in such an act as that referred to even at common law; for in such a case, as Chief Justice Shaw remarked, if the woman’s death ensued, the party making the attempt would be guilty of murder, and this whether the woman consented or not; for the act is done without lawful purpose, is dangerous to life, and the consent of the woman no more annuls the legal imputation of malice than it does in the case of a duel. And furthermore, as to the child produced by a criminal abortion, if it fairly live after birth and then die from injuries received in the body of the mother before its birth, it is clearly a case of homicide. In Pennsylvania the courts dissent from the view as to the common law which is taken in the states first mentioned. It was there declared that miscarriage, both in law and in physiology, means the bringing forth of the fœtus before it is perfectly formed and capable of living, and that it was of itself a flagrant crime at common law to attempt to procure the miscarriage or abortion of a woman; that it was a crime against nature which obstructed the fountain of life, and therefore it was punishable. To the objection on the part of the prisoner that the indictment was defective, because it ought to and did not allege that the woman was quick with child, it was answered by the court that that was not the law in Pennsylvania, and ought not to have been anywhere; that it was not the murder of a living child which constituted the offence, but the destruction of gestation by wicked means and against nature; and that the moment the womb is instinct with embryo life and gestation has begun, the crime may be committed.—But practically the actual law on the subject exists only in the statutes. The principal English acts of modern times are those of 43 George III., ch. 58, § 2; 9 George IV., ch. 31, § 14; 7 William IV.; and 1 Victoria, ch. 85, § 6; all of which are displaced by the present law of 24 and 25 Victoria, ch. 100, §§ 58, 59. The first of these acts, known as Lord Ellenborough’s act, provided that any person who should wilfully, maliciously, and unlawfully use means . . . with intent to cause and procure the miscarriage of any woman being quick with child was a felon, and should suffer death; and the act further provided that in any such case, if the woman was not found to be quick with child at the time of the commission of the act, the offender should be guilty of a felony and liable to fine, imprisonment, pillory, transportation, &c. The statute of 9 George IV., ch. 31, known as Lord

Lansdowne's act, did not differ substantially from the former, but further provided against the use of instruments. The next statute provided that whosoever, with intent to procure the miscarriage of any woman, should use unlawful means, &c., should be guilty of felony and liable to transportation for life or not less than 15 years. The present statute provides that every woman being with child who, with intent to procure her own miscarriage, shall unlawfully administer to herself drugs, or use instruments, and whosoever with similar intent, whether the woman be or be not with child, shall use the like unlawful means, shall be guilty of felony, and liable on conviction to penal servitude for life or not less than three years, or to imprisonment. Supplying or procuring anything knowing that it is to be used with intent to procure the miscarriage of any woman, whether she be or be not with child, is a misdemeanor.—Of the more recent statutes in the United States, that of Maine (revision of 1871) provides that whoever administers, &c., to any woman pregnant with child, whether such child be quick or not, &c., if the act is done with intent to destroy the child, and the child is destroyed before birth, shall be punished by imprisonment not more than five years or by fine not exceeding \$1,000; and if done with intent to produce the miscarriage of such woman, by imprisonment not more than one year and by fine of not more than \$1,000. The statute of Illinois of 1869 enacts that any person who by any means shall cause any pregnant woman to miscarry, or shall attempt to procure or produce such miscarriage, shall be liable to imprisonment not less than two nor more than ten years; and if by any such attempt the death of the woman shall be caused, the party offending shall be guilty of murder, and be punished as the law requires for that offence. But this crime may be committed, as has already been shown by the opinion of Chief Justice Shaw, independently of any statutory provision to that effect. In Missouri (revision of 1870) the wilful killing of an unborn quick child by any injury to the mother which would be murder if it resulted in the death of the mother, is manslaughter in the first degree; and every person who shall use means, &c., on a woman pregnant with a quick child, with intent thereby to destroy such child, unless the act is necessary to preserve life, &c., shall, if the death of such child or mother ensue from the means so employed, be guilty of manslaughter in the second degree; and every person who shall wilfully administer to or use means on any pregnant woman with intent thereby to procure an abortion, unless necessary to save life, or advised by physicians to be so necessary, is guilty of a misdemeanor, and is punishable by imprisonment for one year or by fine of \$500, or by both. In Pennsylvania the statute (1860) provides that if any person shall unlawfully use means on any woman pregnant or quick with

child, or supposed to be so, with intent to procure the miscarriage of the woman, and she, or any child of which she may be quick, shall die in consequence of such unlawful acts, the offender is guilty of a felony, and is liable to fine not exceeding \$500 or to be imprisoned not exceeding seven years; and it is further provided that if any person, with intent to procure the miscarriage of any woman, shall use unlawful means upon her, he shall also be guilty of felony and subject to a fine not exceeding \$500 and to imprisonment for not more than three years. The latest statutes—for example, those of New Jersey, Illinois (1869), Kansas (1868), and New York (1869)—do not require that the woman be quick with child, but only that she be “pregnant” or “with child.” The Ohio statute of 1867 is to the same effect, but differs in its phraseology from the statutes of any of the other States. It provides that any person who shall administer or advise to be administered to any woman pregnant with a vitalized embryo or fetus, at any stage of utero-gestation, any medicine or substance, or employ any other means, with intent thereby to destroy such vitalized embryo or fetus, unless necessary or advised by physicians to be necessary to save the life of the mother, shall, in case of the death of such embryo or fetus or mother in consequence thereof, be guilty of a high misdemeanor, and punishable by imprisonment from one to seven years. In Massachusetts, by the present statute, the offender is guilty of felony if the mother die in consequence of the act, and is liable to imprisonment from five to twenty years; and if she does not die, is guilty of a misdemeanor and punishable by fine and imprisonment not more than seven years. The present statute of New York was enacted in 1869, superseding that of 1846. This earlier act declared that every person who should administer to any woman pregnant with a quick child any drug, or use any instrument or other means, with intent thereby to destroy such child, should in case of the death of such child or of such mother be guilty of manslaughter in the second degree. The act of 1869 omits the word “quick,” saying “with child,” and with regard to the intent substitutes the words “with intent thereby to produce the miscarriage of any such woman;” and it preserves the provision that in case the death of such child or of such woman be thereby produced, the offender shall be guilty of manslaughter in the second degree. It will be observed that the omission of any criterion of quickening, and the provision respecting the death of the child, make the crime possible from the very earliest stage of gestation. Under the former statutes it was also an essential element of the crime that there should be an intent to destroy the child; now that intent is immaterial, and if there was the mere intent to procure the miscarriage, and the death of the child is produced, the crime is committed. The statutes

here selected represent fairly the present state of the statutory law, and especially the more recent legislation on the topic.—In a late case in Massachusetts the court was inclined to hold that an indictment could not be maintained there if the fetus had lost its vitality at the time of the commission of the act, so that it could never mature into a living child. In a similar case in Vermont it was held not essential that the fetus should be alive when the attempt was made. Where the language is general, as for example, "with intent to procure the miscarriage of any woman," it is immaterial whether the woman was or was not pregnant at the time. The "administering" or "causing to be taken," usually mentioned in the statutes, does not require an actual delivery by the hand of the defendant. Thus it has been held that one administered poison to another by mixing it in her coffee and putting it in her way. And these words have been held to be answered by proof that one gave the drug to the woman with directions how to use it, and she did use it, though not in the defendant's presence. In New Jersey, under a statute which provided that if any person maliciously or without lawful justification, with intent to cause the miscarriage of a pregnant woman, should advise or direct her to take any drug, it was held that the actual taking or swallowing of the drug by the woman was no element of the crime; the defendant was guilty within the statute if only he gave the advice with the intent there declared. In this case the court added that the design of the statute was not to prevent the procuring of abortions so much as to guard the health and life of the mother against the consequences of such attempts. The word "malicious" in these statutes does not require proof of cruelty or wantonness or revenge. It is enough that there is no legal justification; and there is no such justification in the consent of the woman, nor though the real motive was to screen one or both of the parties from public exposure and disgrace. The patient in cases of abortion is not technically an accomplice in the offence so as to be disqualified from testifying; but as she is in almost all cases, by virtue of her consent, implicated in the moral wrong, this circumstance would fairly affect her credibility. Where the statute simply requires, as in Massachusetts, that the act shall have been done "unlawfully," the indictment need not charge that it was malicious and without lawful justification; and the word unlawfully precludes any possibility of inference that the act was done for the purpose of saving the life of the woman, or under any other circumstance which would afford a legal justification. The present statute of Ohio (1867) makes it a misdemeanor to print or publish advertisements of drugs for the exclusive use of women, or of any means for preventing conception or producing miscarriage, or to keep any such articles for sale or gratuitous distribution. A similar statute was

passed in New York in 1869, and in Pennsylvania in 1870.

ABOUKIR, an Egyptian port about 12 m. N. E. of Alexandria. In the bay of Aboukir was fought, Aug. 1, 1798, the famous battle of the Nile or of Aboukir, between the French fleet sent out from Toulon under Bruceys with Bonaparte and an army on board, and the English fleet sent in pursuit under Admiral Nelson. Though the French fought desperately, the engagement, which was begun at dusk, ended at daybreak in a great victory for the English. Only four French vessels escaped; the French lost more than 5,000 men; the English killed and wounded were but 895. Nelson was slightly, Bruceys mortally wounded. The story of the battle is filled with examples of individual bravery on both sides.—At Aboukir, on July 23, 1799, Bonaparte, with a comparatively small force, almost annihilated the Turkish army under Mustapha Pasha.

ABOUT, Edmond, a French author, born at Dieuze, Meurthe, Feb. 14, 1828. He was educated at Paris, and in the French school at Athens. His literary talents had already become noted when in 1855 he published *La Grèce contemporaine*, which made him celebrated both at home and abroad. He next produced in the *Revue des Deux-Mondes* a novel entitled *Tolla*, which became the occasion of a controversy, in which he was accused of publishing private papers. After this he brought out novels and plays very rapidly, and contributed much to the press. His *Roi des montagnes* (1856) increased his reputation as a witty, pungent writer. Though not generally successful as a playwright, he made a hit by his play entitled *Risette, ou les millions de la mansarde* (afterward called *Gaetano*), in which sharp political and religious allusions abound. His most popular novels are *Germaine* (1857) and *Madelon* (1863). He has also published *Rome contemporaine* (1863), *Le Progrès* (1864), *L'Assurance* (1866), *LA B C du travailleur* (1868), and *Le Fellah* (1870). As a contributor to the *Gaillois* newspaper (1867-'70) he criticised the ministers of Napoleon III., while he paid court to the emperor himself, who made him an officer of the legion of honor in 1867, and in February, 1870, appointed him member of the council of state. On the outbreak of the war in July, 1870, he accompanied MacMahon's army to Alsace, as correspondent of the *Soir* newspaper; but after the battle of Wörth he barely escaped falling into the hands of the Germans. He continues (1872) his connection with the *Soir*. His marriage in 1864 with Mlle. de Guillerville, of Roncheolles, near Rouen, made him affluent.

ABRACADABRA, a magical word with the ancients, supposed to possess some talismanic properties when inscribed and partially repeated in a triangular form, so as to be read in different directions, upon a square piece of paper or line, folded and worn as an amulet or variously used in incantations.

ABRAHAM (originally **ABRAM**), the first patriarch of the Hebrews. See **HEBREWES**.

ABRAHAM À SANCTA CLARA, a German preacher, whose proper name was **ULRICH VOX MEGERLE**, born at Krähnenheimstetten in Swabia in 1642, died in Vienna, Dec. 1, 1709. He was an Augustinian monk, and preached such witty and powerful sermons that the German emperor appointed him court chaplain. He wrote "Hotch Potch," "Judas the Arch Knave," "Fie and Shame on the World," &c.

ABRANTES, a town in Portuguese Estremadura, at the head of navigation on the Tagus, 80 m. N. E. of Lisbon; pop. in 1863, 5,590. It is surrounded by a very fertile and highly cultivated plain, dotted with villages and villas, but is chiefly important as a military position, commanding one of the frontier roads from Spain into Portugal.

ABRANTÈS. I. Andoche Junot, duke of, a French soldier, born at Bussy-le-Grand, Burgundy, Oct. 23, 1771, died in Montbard, July 29, 1813. He was educated for the law, but in 1792 enlisted in the army as a volunteer, and by his courage won the sobriquet of "the Tempest." He attracted Bonaparte's attention at the siege of Toulon, and a close intimacy sprang up between the two. Junot's devotion to his superior amounting almost to fanaticism. He accompanied Bonaparte to Italy as his aide-de-camp, and won the rank of colonel in the campaign of 1797. He distinguished himself in Egypt, and was made brigadier general. A wound received in a duel with a brother officer, who was not as enthusiastic a Bonapartist as himself, delayed his return to France, and he landed at Marseilles on the day of the battle of Marengo. He was forthwith appointed to the command of Paris, and a few months later married Mlle. Laure de Permon, and was made general of division. But his own as well as his wife's indiscretions were so distasteful to Napoleon, that in 1803 he removed Junot to the command of one of the corps of the "army of England." On the establishment of the empire Junot was promoted to the rank of colonel-general of the hussars, received a pension of 30,000 francs, and a little later the grand cross of the legion of honor; but he could not conceal his disappointment at not having been placed among the first marshals of the empire. His dissatisfaction, his improper behavior and lavish expenditures, coupled with his wife's eccentricities, caused the emperor to send them for a while into honorable exile; and Junot was in 1805 appointed ambassador to Lisbon, where he distinguished himself only by ostentation. In the same year he went to Germany without permission, and arrived in time to participate in the battle of Austerlitz. In 1806 he was again appointed governor of Paris and commander of the first military division; but his follies again compromised him, and in 1807 he was sent to Spain to take command of the army that was to invade Portugal. At the head of 25,000 men, hastily collected and ill

provided, he marched from Salamanca Nov. 12; reached the frontier at Alcántara amid extreme privation and suffering; gained the town of Abrantes, whence his title of duke, Nov. 23; and, without pausing a moment, seized Lisbon (Dec. 1), at the head of only 1,500 grenadiers, most of whom were so worn out that they seemed to be only walking skeletons. Displaying enormous activity, he got possession of the principal fortresses of the kingdom, and reorganized and strengthened his exhausted forces; but his success was soon checked by the arrival of Sir Arthur Wellesley with an English army. Junot was defeated at Vimieira, and constrained by the convention of Cintra, Aug. 22, 1808, to evacuate Portugal. Landed at La Rochelle with his troops by the English fleet, he immediately joined Napoleon, who took him back to Spain, where he was placed in command of the third corps, then besieging Saragossa. He participated in the campaign of 1809 in Germany, and in 1810 was sent back to Spain, where he was severely wounded in the face by a bullet. In 1812 he commanded a corps of the invading army in Russia; but his slow operations did not satisfy the emperor, who, instead of employing him actively the next year in Saxony, appointed him commander of Venice and governor general of the Illyrian provinces. This kind of disgrace, combined with other troubles and the suffering from his old wounds, preyed so much upon him that he became insane, and was taken to his father's house at Montbard, where he threw himself from a window and died from the effects of the fall. **II. Laure Permon Junot**, duchess of, wife of the preceding, born in Montpellier, Nov. 6, 1784, died at Chaillot, near Paris, June 7, 1838. Her mother, a Corsican, claimed descent from the Comnenus family. Her father, M. Permon, made a fortune by provisioning Rochambeau's American troops, but lost it before his death (October, 1793). The mother lived in good style at Paris, and her house was frequented by Bonaparte, Junot, and other distinguished persons. Bonaparte, according to her daughter's *Mémoires*, wished to marry her, though she was old enough to be his mother. Mlle. Permon became the wife of Junot in 1800, the first consul giving her rich presents, both then and many times afterward. This munificence encouraged Mme. Junot in a course of extravagance which, as well as her other indiscretions, eventually proved disastrous to her fortunes. Napoleon's friendship for her was also said to have excited the jealousy of Josephine, while her excessive love of finery and her sharp tongue made him call her *petite peste*. While in Madrid and Lisbon with her husband, her lavish expenditure and her regal pretensions caused astonishment. At Neuilly she hired a palace known as the Folie St. James, where she performed in private theatricals, in which she excelled. Even while following her husband in the Spanish campaign, she kept up her Parisian style of entertainments in the various

encampments of the army. At the same time she bore all the fatigues of the war with great fortitude. While at Lyons she paid a visit to Mme. Récamier, and, courting the society of other persons who were not liked by Napoleon, she incurred his displeasure, and was not permitted to reside in Paris. Her husband, too, having forfeited the good will of the emperor, was banished from Paris, though he was in a dying condition; and the duchess, while attempting to see him at Montbard, where he died, was taken ill. In spite of Napoleon's orders she went to Paris in September, 1813, and her house became once more the centre of distinguished persons, especially after the restoration of the Bourbons, toward which she had contributed. In 1817 she took up her residence at Rome. Having sold the magnificent library and the other valuable legacies of her husband, and being at the end of her resources, she entered into a contract for the publication of her writings. At the time of the July revolution, 1830, she lived in retirement at the Abbaye-aux-Bois, near Paris, and in 1831 began the publication of the *Mémoires ou Souvenirs historiques sur Napoléon, la Révolution, le Directoire, le Consulat, l'Empire et la Restauration* (18 vols. 8mo, Paris, 1831-'34). She also wrote memoirs of her experience in France, Spain, and Portugal, and many novels and stories, besides contributing to periodicals; but her literary fame rests chiefly on her brilliant gossip and overflowing anecdotes relating to the court of Napoleon. Notwithstanding her incessant literary activity, she remained very poor, and died at Chaillot two days after her removal to a private hospital in that place. Louis Philippe sent some money for her relief, but she died before it reached her. Ignazio Cantù published in 1837 *Relazione della duchessa d'Abrantès*, and A. D. Roosmalen in 1838 *Les derniers moments de la duchesse d'Abrantès*. **III. Napoléon Andoche Junot**, duke of, son of the preceding, born in Paris in 1807, died there in March, 1851. Obligated to leave the diplomatic service on account of his scandalous private life, he became known in light literature by a variety of works of ephemeral reputation, the principal among them being *Les boudoirs de Paris* (6 vols. 8vo, Paris, 1844-'5). **IV. Adolphe Alfred Michel Junot**, duke of, brother and heir of the preceding, born at Ciudad Rodrigo, Spain, Nov. 25, 1810, died in July, 1859. He was aide-de-camp of Gen. MacMahon in Algeria (1848), and of Prince Napoleon in the Crimea (1854), served with a high rank in the Italian war, and died from a wound received at the battle of Solferino. **V. Joséphine Junot d'**, sister of the preceding, born in Paris, Jan. 5, 1802, married in 1841 M. James Amet, after having been previously a sister of charity and canoness. She is the author of a number of stories and novels published under her maiden name. The best known of them are: *Histoires morales et édifiantes* (1837); *La duchesse de*

Valombray (2 vols., 1838); and *Étienne Saulnier* (2 vols., 1850). **VI. Constance Junot d'**, sister of the preceding, born in Paris, May 12, 1803, is the wife of M. Louis Aubert, for some time editor of the *National* newspaper, and in 1848 prefect in Corsica. Under the name of Constance Aubert she has been connected with periodical literature as a writer on fashions, manners, and customs. In 1859 she published a *Manuel d'économie élégante*, and in 1865 a little volume on the luxury of women (*Encore le luxe des femmes: Les femmes sages et les femmes folles*).

ABRAVANEL, **Abrabanel**, or **Abarbanel**, **Isaac ben Judah**, a Jewish author, born in Lisbon in 1437, died in Venice in 1508. His family boasted a lineal descent from the kings of Judah. He received an excellent education, and was equally successful in the pursuit of knowledge, wealth, and influence. Alfonso V. of Portugal employed him in state affairs; but his son and successor, John II., not only withdrew all favor from him, but, unjustly suspecting him of intrigues with Spain, caused him to fly to that country, and confiscated his property. He sought consolation in study, but after a time entered the service of King Ferdinand of Aragon. The expulsion of the Jews from Spain, decreed in 1492 by Ferdinand and Isabella, again made him an exile. Repairing to Naples, he was well received by Ferdinand I., and by his son Alfonso II.; but the invasion of the French in 1495 drove him with the Neapolitan court to Messina, whence he repaired to Corfu. In 1496 he established himself at Monopoli in Apulia, where he remained till 1503. The last years of his life he spent in Venice, where he once more engaged in state affairs. His works, the principal of which are commentaries on various books of the Scriptures, partly of a critical and partly of a doctrinal character, and a number of philosophical treatises, are marked by a glowing enthusiasm for Judaism, a comparative independence of spirit, vast research, and elegant Hebrew diction. One of his three sons, **LEONE** (originally Judah) was the author of a philosophical work in Italian, entitled *Dialoghi di Amore*, which passed through several editions.

ABRAXAS (Gr. *αβραξας* or *αβρααξ*), a mystical word employed by the Egyptian Gnostic Basilides to signify the Supreme Being as ruler of the 365 heavens of his system, which number is represented by its letters according to Greek numeration; probably in imitation of the significance attached to the name of the Persian god Mithras (*Μεθραξ*), the letters of which have the same numerical value. Some authorities, however, give the word other derivations and different significations as a designation of the Supreme Being.—Many ancient stones or metallic tablets called Abraxas gems or images, or Basilidian stones, have been found, chiefly in Egypt, Syria, and Spain. They are generally inscribed with the word Abraxas or Abrasax, and sometimes with others, and bear a great

variety of Gnostic and other mystical symbols, occasionally perhaps merely natural markings. They were used as amulets, and supposed to be endowed with miraculous qualities.

ABRUZZO, or the **Abruzzi**, the northernmost division of the former kingdom of the Two Sicilies, now forming part of the kingdom of Italy, embracing the highest and wildest portion of the Apennines. The mountains are the home of a race of shepherds, who are clothed primitively in untanned sheepskins, and the valleys and lowlands are very fertile. The inhabitants live in dirty huts, shared by the donkey and the pig; their chief food is Indian meal, boiled in water and milk; wheaten bread is a luxury. They are musical, hospitable, superstitious, and revengeful. Physically they are a fine race of men, and make excellent soldiers, like their predecessors in Roman times, the Samnites. Fierce brigandage has long found an almost impregnable foothold in this wild region. It is divided into the following three provinces: **I. Abruzzo Citeriore**, bounded N. E. by the Adriatic; area, 1,105 sq. m.; pop. in 1871, 339,961. The mountains of La Majella are the roughest part of the province. The chief productions are grain, oil, and rice. The greatest abundance of wine is furnished by Ortona; the best by Chieti and Vasto. Fruit and kitchen vegetables are chiefly grown at Chieti; swine are reared in the oak forests, and the sea on the coast is rich in fish. The culture of silkworms and of mulberry trees has of late made great progress. The province is divided into the districts of Chieti, Lanciano, and Vasto. Capital, Chieti. **II. Abruzzo Ulteriore I.**, bounded S. by the preceding, and also lying on the Adriatic; area, 1,283 sq. m.; pop. 245,617. The Pizzo di Sevo, 7,860 feet high, is the chief summit. The province grows and exports a large quantity of grain. There are numerous plantations of olives, but the product is of an inferior quality. The culture of wine is rapidly increasing. The province is divided into the districts of Teramo and Penne. Capital, Teramo. **III. Abruzzo Ulteriore II.**, bounded N. E. by the two preceding, N. by Umbria, and S. W. partly by the former Papal States; area, 2,126 sq. m.; pop. 333,791. Three fourths of the area consists of sterile rocks and mountains. The number of large mountain peaks is no less than 176. In the middle of the northern frontier is the highest mount of the peninsula, the Gran Sasso d'Italia, 9,392 feet high. Among the productions are grain, rice, wine, saffron, olives, and many kinds of fruits. The mountains are covered with extensive forests of oaks, beeches, and elms, which harbor bears, wolves, and boars. On the Gran Sasso chamois are still said to be found. Madder grows wild on the Alpine heights, and is cultivated in sandy places. Hams, salted beef, and sausages are exported. The province is divided into the districts of Aquila degli Abruzzi, Avezzano, Cittaducale, and Solmona. Capital, Aquila.

ABSALOM, the third son of David, his only one by Maachah, and especially distinguished for beauty. Instigated possibly by ambition, but ostensibly by the rape of his sister Tamar, he slew Amnon, his eldest half-brother, and subsequently raised a rebellion and obtained a momentary possession of the throne. By the adroit management of Joab he was overthrown and slain. With all his want of filial affection, David loved him, and mourned his death.

ABSALON, or **Axel**, a Danish statesman, soldier, and ecclesiastic, born in 1128, died in 1201. He was educated at the university of Paris. He was related to the royal family, and was the chief minister and general of Waldemar I. (1157-82) and Canute VI.; was elected bishop of Roeskilde in 1158, and archbishop of Lund and primate of Scandinavia in 1178; and was equally distinguished for piety, statesmanship, and military skill and valor. He put down the Wendish pirates who infested the Baltic, followed them up to their island home of Rügen, destroyed the temple of their god Svantevit at Arkona, and forced them to receive Christianity. The code of Waldemar was partly his work, as also the ecclesiastical code of Seeland. On his encouragement, Saxo Grammaticus composed his history of Denmark, the first continuous Scandinavian history ever written. Later he overcame the Pomeranian prince Bogislas, and made him do homage to the Danish king. He constructed a little fort, named after him Axelhuus, for defence against pirates, around which Copenhagen was gradually reared.

ABSCESS (Lat. *abscedere*, to separate), a collection of pus in a circumscribed cavity. (See Pus.) This cavity is usually of new formation, produced by the separation and destruction of the parts by the matter effused, the wall consisting of a layer of thickened tissue. The name is given, however, to collections of pus in some of the naturally existing cavities; *e. g.*, that in the upper jaw. An abscess may be acute or chronic according to the character of the inflammation which produces it. The formation of an acute abscess is indicated by pain, often of a throbbing character; redness, if it be not too deeply seated; swelling; and an increase in the temperature of the part. The patient also suffers from fever. When matter has formed and is sufficiently near the surface, its presence is made known by the feeling of "fluctuation," produced by placing the fingers of one hand upon one side of the swelling and with those of the other giving a smart tap upon the opposite side. The pus usually tends toward the surface, which it reaches by a gradual thinning of the intervening tissues; but if these be very resisting, it may travel in other directions. It is in these latter cases that an early incision by the surgeon is especially called for, before "pointing" has taken place.—If an abscess be threatened, its formation may sometimes be prevented by appropriate treatment, such as rest, the local abstraction of

blood, and cold or warm applications, as the case may demand. Should these means fail, poultices must be used to promote suppuration. The matter may be evacuated by incision, or in certain cases be allowed to make an exit for itself. In a chronic abscess the pain, redness, increased temperature, and fever are often absent, and hence it is also known as cold abscess. In most cases its progress is slow, and it may remain for a long time without increase in size, or any tendency to open through the skin. Indeed, in some instances it may disappear by a process of absorption. Usually, however, it is necessary to open it, which may be done by cutting directly into the cavity, or by what is known as subcutaneous incision, the knife being passed for some distance beneath the skin before it enters the abscess. This latter procedure is made use of in order to prevent the admission of air, which in some cases excites an amount of suppuration sufficient to exhaust the patient. Besides acute and chronic, abscesses are spoken of as being "by congestion" when the matter, usually dependent on caries, makes its appearance at some distance from the diseased part; as "idiopathic," when the cause is not known, &c.

ABSINTH, or **Wormwood**, the tops and leaves of *artemisia absinthium*, a plant of the order *compositæ* and tribe *scenecionideæ*. It contains a volatile oil and a very bitter, resinous substance called absinthine. It has been used as an aromatic, bitter tonic, and anthelmintic. It derives its chief importance from being a constituent of the French liqueur called *absinthe*. This consists of alcohol holding in solution the active principles, mostly volatile oils, of several aromatic plants besides wormwood. The precipitation of these oils, when the liqueur is added to water, produces whitening or clouding. The continued use of absinthe has been found to give rise in man to symptoms of an epileptic character, not altogether attributable to the alcohol it contains. Experiments have shown that the essence of absinth, in a single large dose, may cause epileptiform convulsions in animals. The brain disease produced by this drug is considered incurable, though temporary respites may occur.

ABSOLON, **John**, an English painter, born in London, May 6, 1815. He is a member of the "New Water Color Society," to the annual exhibitions of which he is still a steady contributor. He paints history and genre with equal facility, and is known as an accomplished draughtsman and colorist. He has attempted oil painting with success, but his special field is water-color drawing.

ABSOLUTE (Lat. *absolutus*, absolved, freed from all extrinsic conditions, complete in itself, and dependent on no other cause), a term much used in modern philosophy, especially by Schelling, Hegel, Cousin, and their followers. As used by them it stands opposed to the relative, for independent, unconditioned, self-existent being, or being in itself, which

they contend is the primitive in all thought, and the ultimate in all science, and the object of immediate intuition. In their language the absolute means, or is intended to mean, the Infinite, God himself, regarded simply as pure being, *Das reine Seyn*. Sir William Hamilton denies that absolute and infinite are identical, and that in the sense of the infinite—the unconditioned—the absolute is an object of intuition. He confines all philosophy, therefore, to the finite, the relative, the conditioned. To think, he says, is to condition, and there is no intuition without thought. The absolute and relative can be thought only as correlatives, each connoting the other, and, therefore, only as conditioned. He is answered by those who profess the philosophy of the absolute, that, although the term may be used to express an idea different from that of the unconditioned, or the infinite, and although to think is, in a certain sense, to condition, yet the condition is, in the thought itself, always apprehended as the condition of the subject, never as the condition of the object. Certainly the finite can apprehend the infinite only in a finite mode or manner, but to apprehend it even in a finite mode or manner is still to apprehend the infinite. It is not necessary to the reality of human knowledge that it should be adequate to the object, for if it were there could be no human knowledge at all. They reply further, that the relative is inconceivable without the absolute. What is not, is not intelligible; and since the relative is not and cannot be without the absolute, the conditioned without the unconditioned, there can be no intuition of the former without a simultaneous intuition of the latter, nor are they intuitively apprehended precisely as correlatives, each as conditioned by the other; for in the intuition itself the absolute is apprehended as the cause or creator of the relative, the unconditioned as conditioning the conditioned. There is another controversy even among those who are termed ontologists, and who profess to find in the intuition of unconditioned being the principle of philosophy—whether the pure being, the absolute, the unconditioned being, asserted by Cousin and the German school, and which they identify, or attempt to identify, with God, is real living being, real living God, or after all only a logical abstraction. A class of modern philosophers, among whom may be mentioned Vincenzo Gioberti as the most distinguished, maintain that, as the terms the absolute, the infinite, the unconditioned are evidently abstract terms, the idea they express is and can be only a logical abstraction, formed by the mind operating upon its own conception, and eliminating from them all conception of space, time, bounds, conditions, or relativity. In this case, they say, it is no real being, but a simple generalization of psychological phenomena, and as far removed from the *ens necessarium et reale*, the real and necessary being of the schoolmen, the real living God, in whom the human race be-

lieve, as zero is from being something. Hence, though for another reason, they refuse to concede with Sir William Hamilton that we have intuition of the absolute, the infinite, or the unconditioned, but assert, in opposition to him, that we have immediate intuition of that which in reality is absolute, infinite, and unconditioned. To suppose that we have intuition of being, or God as the absolute, would be to suppose that we know the abstract before the concrete, the possible before the real, and therefore that reflection or reasoning precedes instead of following intuition. They dissent, therefore, from Schelling, Hegel, and Cousin, and deny that we have immediate intuition of the absolute, that is of God, real and necessary being, as the absolute; and maintain that while we have immediate intuition of that which is absolute, infinite, unconditioned, we conceive the intuitive object as such only by a process of reflective reason—the process by which the human mind demonstrates that the object of its intuition is God.

ABSOLUTION, in the Roman Catholic church, the act of the priest in pronouncing the pardon and remission of the sins of a penitent. Absolution *in foro interno* is a part of the sacrament of penance, in which the guilt of mortal and venial sin is remitted. Absolution *in foro externo* is the remission of certain ecclesiastical penalties, for example, excommunication. There are also precatory forms of absolution, which are used during the divine service. Short prayers at the end of each nocturn in the office of matins are also called absolution. In the morning and evening prayers of the English and American Episcopal churches, absolution is a formula of publicly praying for or declaring the remission of the sins of the penitent, used only by a priest; also, in the "Office for the Visitation of the Sick" of the church of England, an authoritative declaration of the pardon of sin, pronounced over a penitent after private confession. Similar forms of absolution are used in the Lutheran church.

ABSORPTION (Lat. *absorbere*, to suck up). **I.** The process by which nutritious and other fluids are imbibed by animal and vegetable tissues, to be appropriated for their growth, activity, or modification. All the organized membranes and tissues of the living body have the property of absorbing, to a certain extent and under favorable circumstances, the fluids which are brought in contact with them. This property continues to belong to the tissues in question even after the death of the body, or after they have been separated from all connection with the neighboring parts, until their natural structure and composition have begun to be altered by the effects of decomposition. Thus a dried ox bladder will absorb water in which it is immersed, and again become moist and supple; and even microscopic cells and fibres will absorb coloring matters with which the vessels of the tissue have been injected. This shows that the

power of absorption resides in the substance of the animal tissue or membrane itself, and not in any property communicated to it from the rest of the system. Nevertheless, although the capacity for absorption still exists in a separated membrane, it is much less active than in the same tissue during life, for the reason that after death it soon comes to an end by the saturation of the membrane by the absorbed fluid; while during life it is kept in a constant state of activity by the incessant renewal of the fluids and the movement of the circulating blood. In the process of absorption, as it takes place in animal organizations, the fluid does not penetrate the tissues mechanically, by openings or orifices, however minute. The existence of such orifices, or open absorbent mouths, was formerly taken for granted, as the most convenient way of explaining the phenomenon; but later and more complete microscopic examination has failed to show their existence, and takes away all reasonable grounds for the assumption. So far as we can decide upon a question of such delicacy, absorption consists in the imbibition of a fluid by the solid tissue in such a manner that the fluid and its ingredients unite, or combine directly with the substance of the tissue; so that the union which results is not simply a mechanical entanglement, but rather an intimate and complete molecular combination of the two.—It is found that different animal substances have the power of absorbing different liquids in different proportions. Thus an animal membrane which will absorb in a given time 100 parts by weight of pure water, will absorb only 65 parts of a saline solution; and this difference will be greater, within certain limits, the stronger the saline solution is made. A tissue which will absorb 100 parts of a saline solution will take up under the same circumstances only 24 parts of an oily liquid. Thus the activity of absorption varies with the same membrane for different liquids, and with the same liquid for different membranes. Chevreul found the following results by measuring the exact quantities of different liquids absorbed by different membranes and tissues in the same time:

100 PARTS OF		WATER.	SALINE SOLU'N.	OIL.
		231 parts.	125 parts.	
} absorb	Cartilage.....	178	114	8.6 parts.
	Tendon.....	148	30	7.2 "
	Elastic ligament.	24	319	3.2 "
	Cartilaginous do.	461	370	9.1 "
	Cornea.....	301	154	
} hours				
	Dried fibrine....			

Thus, if the same membrane be brought in contact with a liquid containing at the same time a variety of different substances in solution, some of these substances will be taken up in greater abundance than the others; and the membrane accordingly will appear to exercise a kind of discriminative power or selection between these different substances. This power of selection, however, is simply the property, dependent on the natural structure and constitution of the membrane, of absorbing par-

ticular substances in certain fixed proportions, which proportions vary for different materials.—The activity of absorption varies also with other conditions. One of these is the freshness of the animal membrane. While still connected with the neighboring parts, or but recently separated from them, the activity of absorption is great, and a comparatively large quantity of fluid is taken up in a short time. Afterward, when the natural constitution of the membrane is already impaired by commencing decomposition, this activity diminishes, and at last disappears altogether. Another condition of some importance is that of pressure. An increased pressure upon the liquid will enable the membrane to absorb it more rapidly. Pressure and motion combined are still more effective. Thus a medicinal ointment or lotion acts more rapidly and powerfully upon the parts if it be made to penetrate the integuments by brisk rubbing than if it be simply laid in contact with the surface of the skin. Temperature also is of considerable importance. A low temperature is unfavorable to absorption; a high temperature, at least within moderate limits, is favorable to it, and increases its activity. A state of complete liquefaction or solution of the material to be absorbed is essential. A substance which is in the solid form cannot be absorbed; it must first be dissolved either in water or some other appropriate menstruum, after which the solvent fluid and the substance dissolved may both be absorbed, though in different proportions. Even the gaseous ingredients of the atmosphere, which are absorbed in the lungs, are first dissolved in the animal fluids which bathe the respiratory passages, and are then absorbed in the liquid form by the pulmonary membrane. The last and most important condition of the continued activity of absorption is that by which the materials already absorbed by the animal membrane are constantly removed from it, so that it is always ready to take up a fresh supply. If an animal membrane have on one side of it a liquid rich in absorbable materials, and on the other a liquid which is poor in these materials or destitute of them, it will take up these substances from the first liquid, and the second liquid will again absorb them from it. Thus the membrane will not become saturated, but will retain its activity of absorption until the second liquid has approximated in composition to the first. In this way a large quantity of material may pass through the membrane, from the first to the second liquid, combining with the substance of the membrane in its passage, but being constantly taken up by it on one side and discharged on the other. This process will be more active and long continued, the larger the quantity of the two liquids and the greater the difference in composition between them. It will also be more active, the greater is the extent of surface over which the liquids reciprocally come in contact with the membrane,

since it is the absorptive power of the membrane itself which is the primary condition of the interchange of substances between them. The most favorable condition for continued and active absorption would be that in which the two liquids were kept in constant motion and incessantly renewed, so that the first one should never be exhausted of its materials, nor the second saturated with the substances transmitted to it. If, at the same time, the intervening membrane maintained its freshness, unaltered by the changes of decomposition, the process of absorption would go on with the most continuous and uniform activity. These are precisely the conditions, in fact, which are present in the living body. In the alimentary canal, for instance, during digestion, there are constantly passing over the lining membrane of the intestine the nutritious fluids which have been extracted from the food. A portion of these are absorbed by the lining membrane; but, on the other hand, they are immediately taken up from it by the blood in its minute vessels. This blood, in the incessant movement of the circulation, is instantly carried away to another part of the body, its place being taken by other portions of the current following each other without intermission. The living membranes themselves are maintained at the same time in their natural condition by the nutritive process, the temperature of the whole is constantly at or about 100° F., the superfluous materials are decomposed elsewhere, or discharged from the body by the excretory passages, and new supplies are incessantly furnished as the gradual digestion of the food is accomplished.—Experiments have shown that absorption will take place in the living body with considerable rapidity even in non-vascular tissues, or where it is not directly assisted by the circulation of the blood. It has been shown by M. Gosselin that if a watery solution of iodide of potassium be dropped upon the cornea of a rabbit's eye, the iodine passes into the cornea, aqueous humor, iris, lens, sclerotic coat, and vitreous body, in the course of eleven minutes; that it will penetrate through the cornea into the aqueous humor in three minutes, and into the substance of the cornea in a minute and a half. In the vascular tissues, however, the rapidity of absorption is often much greater than this. Thus the absorption of oxygen by the blood in the lungs is apparently instantaneous; the change of its color from blue to red, as soon as it arrives in the pulmonary vessels, showing the action of the gas which it has taken up from the atmosphere. This rapidity of absorption in the vascular tissues is due to the dissemination of the blood in a vast number of minute channels, by which the vascular and absorbing surfaces are brought into intimate contact over a large surface; and to the incessant motion of the fluid, by which its effect becomes perceptible at the earliest possible time. It is in some of the glandular organs that this absorp-

tion and reciprocal interchange of fluids has been shown to take place with the greatest activity; for the capillary blood vessels here form an exceedingly intricate and abundant network embracing the adjacent follicles and ducts of the glandular tissue, while these ducts and follicles themselves are arranged in a system of minute ramifying tubes and cavities, penetrating everywhere through the glandular substance. Thus the union and interlacement of the glandular membrane on the one hand and of the blood vessels on the other becomes exceedingly extensive; and the ingredients of the blood are instantly subjected, over a very large surface, to the influence of the glandular membrane, or the fluids which it has absorbed. The rapidity of transudation under these conditions has been shown by the experiments of Claude Bernard and other observers. If a solution of iodide of potassium be injected into the duct of the parotid gland on one side, in a living animal, the saliva discharged by the corresponding gland on the opposite side is immediately afterward found to contain iodine. During the few instants required to perform this operation, therefore, the iodine in solution must have been taken up by the glandular membrane on one side, absorbed from it by the blood, carried by the blood to the heart, again distributed over the body, absorbed from the blood by the glandular membrane of the second gland, and thence discharged with the saliva. It is by this process that all the nutritious elements of the food and drink are taken up from the intestine and finally reach the tissues which they are to nourish. They are absorbed from the cavity of the intestine first by its lining membrane; thence by the blood vessels and the blood contained in them; then transported by the circulation to the distant organs and tissues; and finally absorbed by these tissues from the blood, and united with their own substance. But as each tissue has a special power of its own of absorbing certain materials in preference to others, the same blood will supply its materials to each in different quantities. Thus the bones absorb from the blood a large proportion of calcareous matter, the cartilages a smaller quantity, and the muscles still less. The brain, on the other hand, takes up more water than the muscles, and the muscles more than the bones. Thus every tissue is enabled to maintain its own peculiar constitution, though all are supplied with the necessary ingredients from the same nutritious fluid.—It is now universally acknowledged that the action of drugs, medicines, and poisons takes place in the same way. This action is sometimes said to be local, as where the ingredients of a blister are absorbed by the skin and produce an inflammation of the integument at that spot only; or general, as where opium when introduced into the stomach produces drowsiness or insensibility over the whole body. But in both cases the process is essentially similar. The opium is dis-

solved by the liquids of the stomach, absorbed by its lining membrane, taken up by the blood, and distributed by the circulation all over the body. In this way reaching the brain, it is absorbed by the cerebral substance, and by its action upon the nervous matter causes the narcotism and insensibility which are manifested throughout the system. Thus the general action of an opiate is undoubtedly due to its local action upon the brain, and to the fact that the brain itself, through the nervous ramifications, influences the condition of the whole body. **II. Absorption of Gases by Solids and Liquids.** There are not only porous substances, as earth, charcoal, and animal membranes, which will absorb gases, but solid metals will in many instances do the same. Thus recent experiments have demonstrated the existence of gaseous hydrogen in meteorites falling on the earth, absorbed by them in their wanderings through space, perhaps while passing through some nebula, which the spectroscope has shown to consist of incandescent hydrogen; they bring thence this nebular hydrogen to our earth. The power to absorb hydrogen is especially possessed in a high degree by palladium, which takes up nearly 643 times its own volume of this gas, as proved by Graham, while silver and platinum absorb oxygen, titanium nitrogen, &c. This absorption of gas by metals is called occlusion. Deville and Troost have proved the remarkable fact that red-hot iron and platinum have such a great capacity of absorbing hydrogen, that it passes through these metals as it were through a sieve. The absorption of gases by liquids is still more striking. Water absorbs different gases and holds them in solution, in quantities varying in proportion to the nature of the gas. Thus, at a temperature of a few degrees above the freezing point, it contains when exposed to the air 4 per cent. in volume of oxygen and 2 per cent. of nitrogen; so that the air contained in water is much richer in oxygen than our atmosphere, having in six parts four of oxygen, while the atmosphere contains only one part of oxygen in five of air. The solubility of hydrogen in water is equal to that of nitrogen; while in regard to other gases, one part of water in bulk dissolves under the same circumstances 1.3 parts of laughing gas, 1.8 carbonic acid, 3 of chlorine, 4.4 of sulphide of hydrogen, 5.4 of sulphurous acid, 50.5 of hydrochloric acid, and not less than 1,180 of ammonia. A rise of temperature of some 70° diminishes this power of absorption to about one half, while at the temperature of the boiling point of water most absorbed gases are expelled. With a diminished pressure of say half an atmosphere, about half the gas is expelled; while at an increased pressure of say two atmospheres, more gas can be absorbed. Thus in respect of carbonic acid, for instance, every atmosphere pressure augments the capacity of water to absorb this gas by 1.8 volumes, so that at five atmospheres it absorbs nine times its own volume of the same.

The absorption of gases by other liquids than water is a subject still open for investigation, and has thus far only been determined for a few gases. So Dr. Vander Weyde of New York found in regard to laughing gas, that alkaline solutions absorb more than pure water, and alcoholic liquors most, strong alcohol over five times its volume; solutions of neutral salts in general absorb the same amount as water, except the sulphates, which absorb much less of the gas, while acids absorb the least, especially diluted sulphuric acid, which absorbs only 0.3 to 0.05 of its volume, according to its strength.

III. Absorption of Heat. The capacity of bodies to absorb heat is in direct proportion to their capacity to emit heat. Light-colored, polished, or smooth surfaces possess this capacity in the least degree, while dark-colored and rough surfaces absorb heat very readily. However, according to the late researches of Melloni, this effect depends less upon the apparent color than upon the nature of the coloring material. He also finds that when the heat-giving body is not luminous, the color is without influence; but when it is luminous, the color has great influence. Melloni has also determined the capacity of absorption of heat by different transparent substances. He found that while transparent rock salt absorbed only 8 per cent. of the heat passing through with the light, fluor spar absorbed from 25 to 50, Iceland spar and glass 60, alum 90, and ice 94 per cent.; while for heat emitted from a non-luminous body, the latter substances were totally opaque, absorbing all the heat and transmitting none. Recently Tyndall and Magnus have made researches on the absorbent power of gases, and found that under the pressure of one atmosphere, the source of heat being a copper ball heated to 518° F., the absorption by dry air being accepted as the unit, hydrogen was also 1, chlorine 39, carbonic acid 90, nitrous acid 355, marsh gas 403, sulphurous oxide 710, olefiant gas 970, and ammonia 1,195; which means that the latter two gases absorb respectively 970 and 1,195 times more of the heat transmitted through them than is the case with dry air.

IV. Absorption of Light. The apparent color of all objects is caused by the elective absorption of certain colored rays in the white light, while the remaining are reflected and determine the color of the object. Even the purest white and the most perfectly polished surfaces absorb some of the light. It is the same with the most transparent substances; they all absorb light more or less. In many of these an elective absorption also takes place; colored gems and glass or liquid solutions absorb certain colored rays and let others pass; those which pass determine the color of the substance. Sometimes, besides the absorption of several colors, a color is reflected complementary to that transmitted; in a thin layer of aniline red, red rays are transmitted, while green rays are reflected; a similar action takes place in a solution of litmus and several other sub-

stances. Some crystals possess the power of absorbing different colors when light passes through them in different directions; this is called dichroism and polychroism. Thus the mineral iolite, a gem consisting of alumina, magnesia, and iron, shows different colors according as the light falls along the axis of crystallization or in a transverse direction. Many artificial crystals exhibit the same remarkable property; for instance, the double chloride of platinum and potassium, which appears either deep red or bright green. The investigation of this peculiar kind of absorption of light has recently given rise to the invention of a new modification of the microscope by Haidinger, by which this property may be examined in the minutest crystals; this invention is called the dichroscope and dichroic microscope. **V. Absorption Spectrum.** The elective absorption of transparent gases, liquids, and solids is determined by means of the spectroscopist. This instrument proves indeed that the cause of this absorption is simply the incapacity of the transparent substance to transmit luminous waves of a certain length, and thus that it is opaque for such waves. The result of such partial opacity is the formation of the so-called absorption bands, in case such a substance is placed between the light and the slit of the spectroscopist. The Fraunhofer lines in the solar spectrum are in fact nothing but absorption bands produced by the passage of the light through the solar atmosphere; our own atmosphere also produces such bands, which spectroscopists call the atmospheric lines. The absorption spectrum differs in each substance which we may submit to examination. Thus iodine vapor and nitrous acid vapor produce very characteristic absorption spectra when placed before the slit of the spectroscopist (figs. 1 and 2), while differ-

FIG. 1.—Absorption Spectrum of Iodine Vapor.

FIG. 2.—Absorption Spectrum of Nitrous Acid Gas.

ent solutions of apparently the same color may be unmistakably distinguished from each other by the difference in the absorption spectra

which they produce. The most striking illustration is given by the black absorption bands produced by a perfectly clear and colorless solution of any salt of the rare metal didymium, so that in this way the merest traces of this metal in any solution may be detected, as lately

found by Gladstone and Bunsen. Water, faintly colored yellow with a few drops of blood, may be distinguished from all other solutions of the same color, by showing in the spectro-scope two characteristic absorption bands (fig. 3) in the green portion of the spectrum, not

Fig. 3.—Absorption Spectrum of Blood.

shown by any other substance; and it is even possible to recognize them in a single blood disk, by means of a microscope with spectroscopic eye piece. We add in fig. 4 the absorp-

Fig. 4.—Solar Absorption Lines.

tion bands of the solar atmosphere for comparison; they are used as landmarks to localize the absorption bands of other substances. They were first noticed by Wollaston, but afterward examined with such philosophical refinement by Fraunhofer, that they were named after him, and according to his proposition designated by A, B, C, D, &c. (See SPECTROSCOPE.)

ABSTINENCE, the partial or total deprivation of food. The phenomena which characterize life are connected with chemical changes occurring in portions of the blood or tissues of the body itself; the presence of the substances resulting from these changes being hurtful to the body, they are eliminated from it by the various organs of excretion. This constant loss demands an equivalent supply. If the supply be withheld, the chemical changes still continue and the body wastes; the organism feeds upon itself, and when this is no longer possible, death ensues. The period during which a human being previously in good health can sustain life under a total deprivation of food and drink, is generally stated to be from eight to ten days. This varies, however, under different circumstances. Persons of mature age support abstinence better than those who are younger; women, from the greater development of the fatty tissues, and the less activity of the muscular and nervous systems, better than men; children, in whom all the organic functions are exceedingly active, worst of all. A damp atmosphere which checks exhalation, a moderate temperature, and quiet of body are favorable to the prolongation of life; while muscular exertion, a hot dry air, and a low temperature tend to shorten the period during which it can be preserved. Fodéré (*Médecine légale*) states that some workmen buried in a

damp quarry were extricated alive after a period of 14 days; while after the wreck of the *Medusa*, the sufferers on the raft, exposed to a high temperature and constant exertion, at the end of three days, although they still had a small quantity of wine, were so famished that they commenced devouring the dead bodies of their companions. Water alone tends materially to prolong life. Dr. Sloane (*Medical Gazette*, vol. xvii., p. 389) gives an account of a man 65 years of age, who was rescued from a coal mine after he had been immured 23 days, during the first 10 of which he had a little muddy water. He was so much reduced that he died three days after. The cases of starvation which have been best and most accurately observed, have been those in which the œsophagus has been gradually but at last completely obstructed by cancerous disease. In these cases the deprivation of aliment has been but partial, the patient having been still imperfectly nourished by nutritive injections, which have supported life for a period of five or six weeks. Mental alienation has a marked influence in prolonging the period during which life can be sustained without food. Dr. Willan has recorded a case in which, under the influence of religious delusion, a young man lived 60 days, taking during that time nothing but a little water flavored with orange juice. Dr. McNaughton of Albany (*American Journal of Medical Science*, vol. vi., p. 543) gives a similar instance, during which a young man lived 54 days on water alone. And in a case read in the French academy (*Archives générales de médecine*, tom. xxvii., p. 130), a suicide lived 60 days on nothing but a few mouthfuls of orgeat syrup, before death put an end to his sufferings. Hysterical women often support abstinence in a wonderful manner; but there is in hysteria so much moral perversion, so great a tendency to deceit for the sake of exciting interest and sympathy, that all such cases require to be carefully and closely scrutinized. Most of the instances reported by the old authors, in which total abstinence was endured for months or even years, belong to this category, and are untrustworthy.—The first effect of prolonged abstinence from food and drink under ordinary circumstances, apart from the sensations of hunger and thirst, is pain and distress in the epigastrium, which is relieved by pressure. This subsides after a day or two, and is succeeded by a sense of sinking and weakness in the same region; the thirst at the same time becomes more intense, and is thenceforth the principal source of suffering. Emaciation soon begins to make rapid progress, the eye has a wild glistening stare, the senses are dulled, and the intellect enfeebled; the excretions become rare, scanty, and fetid; the urine is high-colored, often causing a burning pain when passed; often toward the end diarrhœa comes on. The sufferer becomes exceedingly weak, the voice is low and hoarse, the gait slow and tot-

tering, and at length all exertion is impossible; the breath is offensive; the skin is covered with a dirty-looking secretion and exhales a putrid odor. Maniacal delirium often supervenes, and death is sometimes preceded by convulsions. When persons are immured by the falling in of a mine, quarry, &c., they seem subdued by the darkness; but in cases of starvation after shipwreck, or in travelling through an uncultivated country, the worst passions are aroused, and suspicion and ferocity add to the torments of hunger. A high temperature seems to aggravate these passions. "It is impossible to imagine," says M. Savigny, in speaking of the wreck of the *Medusa*, "to what a degree the circulation is quickened under exposure to the burning sun of the equator. The pain of my head was intolerable; I could scarcely master the impetuosity of my movement; to use a well-known phrase, the blood boiled in my veins; all my companions suffered from the same excitement;" and the terrible scenes of blood and crime which passed upon the raft were doubtless owing largely to this cause.—On examination after death the bodies of those dying of starvation are found to be almost bloodless, except the brain which contains its usual quantity, and completely destitute of fat. The various organs, with the exception of the brain, are all reduced in bulk, and the coats of the intestinal canal especially are rendered thinner. M. Chossat (*Recherches expérimentales sur l' inanition*) deprived a number of animals (birds and small mammals) of all sustenance, and carefully observed the phenomena that followed, and his experiments throw much light upon the subject of starvation. The temperature in all the animals was maintained at nearly the normal standard until the last day of life, when it began rapidly to fall. The animals, previously restless, now became quiet, as if stupefied; they fell over on their side, unable to stand; the breathing became slower and slower, the pupils dilated, the insensibility grew more profound, and death took place either quietly or attended with convulsions. If, when these phenomena were fully developed, external warmth was applied, the animals revived, their muscular force returned, they moved or flew about the room, and took greedily the food that was presented to them. If now they were again left to themselves, they speedily perished; but if the external temperature was maintained until the food taken was digested (and from the feeble condition of their digestive organs this often took many hours), they recovered. The immediate cause of death seemed to be cold rather than starvation. The average loss of weight in the animals experimented upon was 40 per cent., varying considerably in different cases, the variation depending chiefly on the relative amount of fat. Weighing the different tissues separately, and arranging them in two parallel columns, according as they lost more or less than 40 per cent., gave the following results:

Parts losing more than 40 per cent.	Parts losing less than 40 per cent.
Fat..... 93.3	Muscular coat of stomach 39.7
Blood..... 75	Pharynx and œsophagus. 34.2
Spleen..... 71.4	Skin..... 33.3
Pancreas..... 64.1	Kidneys..... 31.9
Liver..... 52	Respiratory organs..... 22.2
Heart..... 44.8	Bones..... 16.7
Intestines..... 42.4	Eyes..... 10
Muscles of voluntary motion..... 42.3	Nervous system..... 1.9

Among the most noteworthy phenomena caused by starvation are the offensive effluvia exhaled from the sufferers, the fetor of their discharges, and the rapidity with which the body passes into a state of putrescence. Such a condition of things is peculiarly favorable to the reception of fever and other contagious diseases, and they acquire in such cases an intensity and virulence rarely seen under other circumstances. Thus, as was fearfully seen in Ireland in 1847, pestilence follows in the train of famine. The effects of the prolonged employment of an insufficient diet alone are rarely seen; they are commonly complicated with those of unwholesome air and over-exertion. Of such complication, prisons, work-houses, and charitable institutions have afforded abundant examples on a large scale. One of the most noted of these occurred at the Millbank penitentiary, near London, in 1823. The prison is situated on marshy ground, which is below the level of the adjacent river, but it had previously been reputed healthy. A few months before the outbreak of the epidemic, the amount of dry nutriment allowed each prisoner daily had been reduced from between 31 and 33 oz. to 21 oz., and animal food was almost wholly withheld. The prisoners were at the same time subjected to a low temperature, and to considerable muscular exertion. In a short time they became paler, weaker, and thinner; subsequently, scurvy, diarrhœa, and dysentery made their appearance, and finally low fevers, or headache, vertigo, convulsions, maniacal delirium, and apoplexy. The smallest loss of blood caused fainting. Of 860 prisoners, 437, or 52 per cent., were attacked. Those who had been longest confined suffered in the greatest proportion. The prisoners who were employed in the kitchen, who had an addition of 8 oz. of bread to their daily allowance, were not affected. Another well-marked epidemic, owing to a similar cause, occurred in the establishment for the destitute children of New York, at what was termed the Long Island farms, in the winter of 1839-'40. The diet of the children consisted of bread of an inferior quality, with tea sweetened with molasses, night and morning, and soup made from coarse beef, alternately with the beef itself at noon; in addition the dormitories of the children were crowded and ill ventilated, and they had scarcely any outdoor exercise. "About the middle of December, 1839," says Dr. Morrell, the attending physician of the asylum (New York "Journal of Medicine and Surgery," vol. iii.), "evidences of a constitutional change in many of the children were apparent; they were dull

and inactive, their eyes lacked lustre, and their skins exhaled an offensive odor." Next, many of them were attacked with slight cholera morbus, and afterward an incurable diarrhoea set in, attended with gangrene about the cheeks, the anus, or vagina. In most of these cases sloughing of the cornea took place and the eye was destroyed. When for a length of time the allowance of food, either from its indigestibility or from its limited amount, has been insufficient for the wants of the system, the digestive organs are weakened; the appetite is lost, and the person often loathes food while he is suffering from starvation. In the experiments of Chossat, when turtle doves were placed upon a limited allowance of corn, but with access to water, part of the corn was either rejected by vomiting, accumulated in the crop, or passed unchanged through the bowels.

ABSTINENCE, Total. See TOTAL ABSTINENCE.

ABT, Franz, a German composer, born at Eilenburg, Saxony, Dec. 22, 1819. His early studies were theological, but he abandoned divinity for music, and at the age of 22 became musical director at Zürich. He remained there eleven years, when he became second musical director at the Brunswick court theatre, and was promoted to be first by the grand duke in 1855. He has composed for orchestra, piano, and voice; but it is mainly as a song writer that he has attained his reputation, having composed a great number of songs that have become well known throughout the world. He has also been very successful as a composer of two-part songs, and of four-part songs for male voices. He visited the United States in 1872.

ABUBEKR, the first caliph, born at Mecca about 573, died in 634. Abubekr means "father of the virgin," and this name was given to him when his daughter Ayesha became the favorite wife of Mohammed. His real name was Abd-el-Caaba. He was Mohammed's most trusted adherent, and in 632 succeeded his master in the supreme authority, to the exclusion of the prophet's son-in-law Ali. At the commencement his reign was troubled, first by the relapse of several tribes to idolatry, and then by the springing up of a new sect under Mosseilama. Assisted by the hero Khaled, Abubekr compelled the backsliders to return, and suppressed the rival creed, Mosseilama himself being slain in a battle. He now led his followers to conquest. His generals fell upon the frontiers of the Roman and Persian empires, and their easy success excited the warrior population of Arabia to pour forth. The emperor Heraclius vainly opposed them. Syria and the provinces of the Euphrates were soon overrun and Damascus besieged. Abubekr died in the full tide of conquest, after a brief reign of two years and three months. His tomb is shown by the side of that of the prophet at Mecca. Abubekr was surnamed the Just. His charity was unbounded, while his manner of living was so strict that he pos-

sessed at his death only the one robe he wore, one camel, and an Ethiopian slave. These he bequeathed to Omar, his successor. Abubekr collected the scattered writings and the oral doctrines of Mohammed forming the Koran.

ABUL-CASIM. See ALBUCASIS.

ABULFARAGIUS, or **Abulfaraj,** **Mar Gregorius,** surnamed, on account of his Jewish descent, Bar-Hebraeus, a Syriac and Arabic writer, born in 1226, died in 1286. He was a native of Armenia, and the son of a converted Jew. By his knowledge and virtues he rose to the dignity of bishop of Aleppo, and in 1266 to that of primate of the Jacobite Christians. His best known work is the "History of the Dynasties," treating of the different kingdoms of the world, Jewish, Chaldean, Persian, Greek, Roman, Mohammedan, and Mongol. An edition in Arabic and Latin was published by Edward Pococke at Oxford, 1663, and one in Syriac and Latin at Leipsic, 1789.

ABULFEDA, **Ismail ibn Ali,** a Moslem prince and writer, born at Damascus about 1273, died in October, 1331. He was a descendant of Eyub (or Ayub), the founder of the Kurdish dynasty in Egypt; fought in the campaigns of Sultan Nasir, of Egypt and Syria, against the Tartars; was by him appointed governor of Hamah in Syria, which his ancestors had held in fief, and subsequently acknowledged as sultan of that principality. He was a man of eminent talents as a warrior, a ruler, and a writer. He is chiefly renowned as the author of an extensive historical compilation, in Arabic, embracing both ancient history and the annals of the Moslems, from the time of Mohammed to the year 1328; and of a geographical work, mainly descriptive of Egypt, Syria, Arabia, and Persia, considered the best of its kind in eastern literature. Both have appeared in various editions, in the original as well as in Latin and other occidental translations. Abulfeda also wrote scientific treatises, which have been lost.

ABU SAMBUL. See IPSAMBUL.

ABU SHEHR. See BRSHIRE.

ABU TEMAM, one of the greatest Arabic poets, born in Syria about 806, died at Mosul in 845 or 846. His poems are said to have procured him the favor of the Moslem courts and many thousand pieces of gold, and the Arabs say of him that "no one could ever die whose name had been praised in the verses of Abu Temam." He was also the compiler of three collections of select pieces of eastern poetry, the most esteemed of which, called the *Hamasa*, is praised by Sir William Jones.

ABYDOS. I. An ancient city of Asia Minor, on the narrowest part of the Hellespont, opposite Sestos, originally the possession of the Trojan prince Asius, and later occupied by the Thracians and Milesians. It is celebrated in connection with the army of Xerxes and the immense bridge built by him at this spot. 480 B. C. Here the tragedy of Hero and Leander took place, according to the poetical legend, and here Lord Byron swam across in imitation

Bas-relief at Abydos, Egypt. (From a Photograph.)

of that luckless lover. **II.** An ancient city (originally *This*, now *Arabat el-Matfoon*) of Upper Egypt, on the canal called the Bahr Yusuf, 6 m. W. of the Nile and about 60 m. below Thebes. It was anciently the second city of the Thebaid, the birthplace of Menes, and the reputed burial place of Osiris, and hence a great necropolis. There are numerous very ancient tombs cut in the adjacent hills, but its most remarkable remains are the palace of Memnon and the temple of Osiris. In the latter was discovered in 1818 the celebrated "tablet of Abydos," or Ramses table, at present in the British museum, upon which is inscribed in hieroglyphics a genealogy of the 18th dynasty of the Pharaohs. Dümichen, in his explorations (1864-'5) of the interior of the temple of Osiris, found a new Egyptian table, which Lepsius calls the Sethos table. It is more complete than that of Ramses, contains 65 shields and an uninterrupted record of the kings of the first three dynasties, beginning with Menes, corresponding with the account of Manetho, and is regarded as more perfect than the table of Sakkarah. This discovery is believed to be important in respect to the researches into the most remote eras of Egypt.

ABYLA, one of the pillars of Hercules, at the N. W. extremity of Africa, opposite Calpe (now Gibraltar) in Spain, the other pillar. It was believed by the ancients to have been formerly joined with Calpe, but separated by Hercules, giving entrance to the Mediterranean.

ABYSSINIA (Arab. *Habesh*, signifying a mixture of peoples), a country of eastern Africa, lying S. W. of the Red sea. Its boundaries are not very accurately defined, especially as the name is frequently applied to a much greater extent of territory than that included in Abyssinia proper, which was formerly said

to comprise the three important states of Tigré, Amhara, and Shoa, but from which Shoa has been excluded by some modern geographers. According to Keith Johnston, however, it extends from lat. $7^{\circ} 40'$ to $16^{\circ} 40'$ N., and from lon. $34^{\circ} 20'$ to $43^{\circ} 20'$ E. On the N. and N. W. it is bordered by Nubia and Sennaar, while southward and eastward lie the Galla and Somali countries and Adal. The Samhara land separates Abyssinia proper from the Red sea, which is nowhere less than 90 m. distant from the frontier. According to M. d'Abbadie, the country is called Ethiopia by the natives, who properly employ the word Abyssinia to denote that portion of the population, for the most part professedly Christian, who have lost all idea of tribal differences. Its maximum length is upward of 600 m. and maximum breadth nearly as much; but these estimates are probably approximate, and as the area of the country depends upon them, it cannot be accurately stated. The population is believed to be from 3,000,000 to 5,000,000.—Considered with reference to its physical geography, Abyssinia is an extensive, elevated, and irregular table land, consisting of a series of plateaux of various altitudes, which rise into isolated groups and ranges of flat-topped mountains. This table land runs nearly due N. and S., and slopes from its highest ridge toward the Red sea on one side and the interior of the continent on the other, so as to form an eastern and a western watershed. Toward the swamps and plains of Sennaar and Nubia the descent from this high region is gradual, but it is very abrupt on the east, the seaward slope being about twelve times greater than the opposite slope toward the Nile. The average elevation of the plateaux, which rise terrace-like and with gradually increasing elevation from N. to S., is

between 7,000 and 8,000 ft. Among them, forming river beds sometimes thousands of feet below the general surface of the surrounding territory, wind ravines and gorges of extreme depth, which are among the most striking natural features of the country. Mr. Clements R. Markham, who accompanied the British military expedition to Magdala, classifies the Abyssinian highlands as follows: 1, the region drained by the affluents of the river Mareb; 2, the region drained by those of the Tacazze and Atbara; 3, the region drained by those of the Abai. The first of these is in Tigré, and includes a considerable portion of northern Abyssinia. Here the average altitude of the plateaux is 9,000 ft. above the level of the sea. They enclose numerous extensive valleys, which, although many hundred feet lower, are none of them at an elevation of less than 7,000 ft. A peculiarity of the valleys here is that valley hills

rise from their level tracts, just as mountains rise from the plateaux above. The principal summits of this region are Mt. Sowayra, 10,328 ft., and Arabi Tereeki, near Senafe, 8,560 ft. The next great physical division of the table land comprises the drainage basin of the Tacazze and Atbara rivers. The loftiest district of this region is the rich agricultural plain of Haramat, 8,000 ft. above the ocean level. In the N. W. part of Amhara, which is included in this division of the highlands, the country is lower, not exceeding 6,000 ft. of average elevation; but the province of Semyen contains the highest mountains in Abyssinia, of which the most important peaks are the Abba Jarrat, in lat. 13° 10' N., 15,088 ft., and Mt. Buahat, in lat. 13° 12' N., 14,362 ft. E. of these are the Harat hills and Wadjerat range. The third clearly defined region is that watered by the tributaries of the Blue Nile, comprising

View in the Mountains near Magdala.

the greater portion of Amhara or the former kingdom of Gondar, with an altitude varying in different districts from 5,000 to 7,000 ft. on the plateaux, and attaining a height of 11,000 ft. in the Talba-Waha mountains. The Wadela and Dalanta plateaux, near Magdala, with an elevation exceeding 9,000 ft., are in the W. portion of this region, the river bed of the Jitta, 3,500 ft. deep, running between them. The steep scarped rock of Magdala itself rises to a height of 9,050 ft., its summit being a flat plain 2½ m. long and half a mile wide.—The only important rivers of the country which flow toward the Red sea are the Ragolay, in the north, a perennial stream which loses itself in the sand before reaching the coast, and the Hawash in the south, which forms a portion of the boundary between Abyssinia and Adal,

and is likewise absorbed in the swamps or deserts on its path to the ocean. All the great Abyssinian rivers belong to the Nile basin. Of these the Mareb is the most northern. It rises in the district of Hamasen, flows S. and W. around Serawe, and thence in a N. W. direction through the Nubian province of Taka. In the rainy season its waters reach the Atbara, but during the remainder of the year they disappear in the sand. The Tacazze rises in Lasta from a spring which was first caused to gush forth from the rock, according to tradition, by a blow from the hand of Menilek, son of the queen of Sheba. Its name signifies "the terrible." Flowing northwesterly, it enters, or properly receives, the Atbara at Tomat, in Nubian territory. It is a rapid and impetuous stream, dashing down rocky falls and between lofty pre-

epiceps with a turbulence well denoted by its name. Further S. is the Abai, the celebrated Nile of Bruce, although the Bahr-el-Azrek or true Blue river rises in the Galla country under the name of the Dedhesa, and the Abai is in reality only its largest tributary. The latter rises S. of the Tzana lake, and making a northward circle through it, turns southward and joins the Bahr-el-Azrek near lat. 11° N. This lake, also called the Dembea, is situated in a grain-producing region of great fertility, at a height of 6,110 ft. above the level of the sea. It is about 50 m. long by 25 m. wide, and its depth in some places is said to be 600 ft. There are many other lakes, among which Ashangi, 4 m. long and 3 m. broad, in the country of the Azebo-Gallas, is the most noteworthy as being a fresh-water lake without any visible outlet. Thermal springs occur in many districts.—The characteristic feature of the climate of the Abyssinian highlands—including Tigré, Amhara, and Shoa—is the occurrence of a tropical monsoon or rainy season from the middle of June to the end of September. Otherwise, the climate is strictly temperate. There is a cold season extending from October to February, with an estimated mean temperature of 58.3° , during which the days are pleasant and the nights cold with heavy falls of dew. The hot weather begins about March 1, and lasts until the monsoon sets in, April being the warmest month. The mean temperature of this season at Magdala is 65.5° , and of the wet season about 5° lower. The rainfall of the monsoon extends over all of Abyssinia proper, but is greater in the south and west than in the north and east. The prevailing winds during the rainy season are easterly and southeasterly. Thunder storms are of frequent occurrence.—The chief agricultural productions are barley and oats on the elevated plains, and wheat, maize, millet, rice, cotton, coffee, and a small native grain called *teff*; in the lower districts. Sugar cane, flax, and beans are raised in small quantities, and lemons, oranges, and figs are occasionally produced. The grape thrives in some parts of Tigré, but no good wine is made.—Volcanic rocks constitute the principal formation in the geological structure of Abyssinia, and cover almost the entire table land. The trappean series appears to be divisible into at least two distinct groups. The lower of these is largely composed of red basalts, on which the disintegrating effects of atmospheric action are plainly marked. Blanford names this the Ashangi group, and that above it the Magdala group; which last comprises trachytic rocks containing many feldspar crystals, and is distinguished by the scarped and precipitous forms which it assumes under the influence of the weather. These forms are characteristic of Abyssinian scenery, and the ambas or hill forts, the great strongholds of the country, are rendered almost inaccessible to an enemy by their situation on the horizontal beds of this rock which surmount the summits usually se-

lected for military stations. In the N. E. provinces, however, metamorphic rocks occupy the whole surface, except in several districts of

Hill Fort between Mai and Abaca.

limited extent where they are overlaid by sandstones, limestones, or igneous formations. They extend 150 m. along the meridian of $39^{\circ} 30'$, between lat. $15^{\circ} 55'$ and $13^{\circ} 50'$ N. At Tehelga coal deposits are found, which geologists are disposed to group with these sandstones of Adigerat. Further S., in the Antalo district, a considerable number of fossils have been obtained from the limestones which predominate there, whereby it has been ascertained that the formation belongs to the oölitic period. The present geological aspect of Abyssinia, with its weather-worn battlements of rock and its deeply scored river beds, must be attributed to fresh-water denudation. There is no evidence of marine action anywhere in the interior, although it is believed that at an early epoch the waters of the Red sea and the Indian ocean may have washed the foot hills of the eastern slope. The volcanic formations along the coast belong to an age much more recent than that which gave rise to those of the table land which have already been described. There are no volcanoes in the country. The only metallic products are gold, which occurs rarely and is of an inferior quality, and iron, of which the yield is consumed at home. Extensive deposits of salt occur on several plains in Tigré.—The distribution of Abyssinian animals seems to be regulated by the altitude of the

various portions of the table land above the sea, each zone of elevation being characterized to some extent by its own particular fauna. It is a noteworthy fact that many of the mammals common to other countries are here distinguished by a much bolder demeanor toward man than that which they exhibit elsewhere. Elephants are numerous near the coast, and go up to the highlands, even 8,000 ft. above the sea, in the summer months; though the rhinoceros, only one variety of which (*R. keitlou*) is met with, does not range higher than 5,000 ft. Many of the elephants are tuskless, but they are all active and savage. The rhinoceros is the black, two-horned species, and feeds on foliage, seldom eating grass. Of the cat tribe, there are at least three species in addition to the Abyssinian lion. The spotted hyena (*H. crocuta*) and two species of jackal are exceedingly common. Of the quadrupeds, the great dog-faced baboon (*Cynocephalus hamadryas*) is found almost everywhere. That peculiar little pachyderm, the hyrax, inhabits its favorite haunts among the rocks at almost every elevation in Abyssinia from 2,000 ft. above the sea upward. The ornithology of Abyssinia is rich in species, no fewer than 293 having been described by Blanford. Among the birds of prey are found the eagle, the vulture, and the handsome Abyssinian lammergeyer, as well as numerous falcons and kestrels. Honey birds, starlings of beautiful plumage, crows, pigeons, several varieties of the cuckoo, swallows, larks, partridges, geese, ducks, and guinea fowls abound. With the exception of lizards, there do not seem to be many reptiles in the highlands. A tree snake, a viper, and several other species of serpent occur; two species of tortoise, and frogs and toads in large numbers, are also met with. The crocodile and python inhabit the tropical districts.—The agricultural products of the country have already been enumerated. The vegetation of the coast lowlands consists principally of acacias, which are replaced by sycamores, dahros (*ficus religiosa*), and mimosæ, in ascending toward the interior. In the passes, the beautiful candelabra tree (*euphorbia Abyssinica*) is found. At an elevation of 6,000 ft. occur juniper trees, which here grow tall and large, the jujube, wild olives, and several trees of the fig tribe. This vegetation is sub-alpine, and common to the plateaux. The flora of the higher regions is characteristic of the temperate zone, the only tree being the juniper, which grows merely as a bush on the loftier mountain sides and summits, together with lavender, thyme, gentian, and the wild rose. Large dahro trees are generally found about the villages, and a variety of willow occurs near streams and in damp places; but though there are some trees on the plains below the plateaux, low bushes form the greater proportion of their vegetation. In fact, the only thickly wooded localities are the gorges and ravines.—Each of the three principal polit-

ical divisions of Abyssinia, Tigré, Amhara, and Shoa, is subdivided into numerous smaller provinces. Formerly the rulers of these three sovereignties were subject to the monarch of the country, but on the decline of the central power in the last century they became practically independent. The town of Adowa, with about 8,000 inhabitants, is the metropolis of Tigré. Gondar, the seat of government in Amhara, and formerly the residence of the Abyssinian kings, is situated in the district of Dembea, N. of the Tzana lake, and has a population estimated at 50,000. Ankobar, a town containing about 12,000 people, is the present capital of Shoa. The inhabitants of Abyssinia are usually classed into: 1, the Ethiopic people of Tigré, speaking a corrupt form of the ancient Geez language; 2, the Amharic tribes, living in Amhara and Shoa; 3, the Agows, of Wag, Lasta, and other provinces, who are by some conjectured to be of Phœnician origin. Besides these are the Gallas who have settled in Amhara and Shoa. Coptic Christianity is the prevailing faith, but there are many Mohammedan and Jewish communities. (See ABYSSINIAN CHURCH.) In point of morality, the latter are generally superior to the Christians. Education is confined almost solely to those intended for the church. Superstition is widely prevalent, and the people are strongly addicted to sensuality and bloodshed. Many peculiar customs prevail, and something of a literature once existed; but the effect of the long series of civil wars has been to render Abyssinian civilization unworthy of the name. Latterly the rule of the lesser chiefs throughout the country has been the only government of any stability.—The history of Abyssinia surpasses in interest that of any other country of Africa except Egypt. Its earliest traditions concern the queen of Sheba, who is said to have ruled over the powerful kingdom of Axum, holding her court at the town of that name, whence she proceeded on her celebrated visit to Solomon. All subsequent legitimate rulers of the nation or of the larger states have claimed to be descended from her. About A. D. 320 the patriarch of Alexandria consecrated Frumentius bishop of Abyssinia. Through his efforts and those of his successors, all of whom bore the title of *abuna salamah* (our father of peace), the Coptic church was firmly established. In 522 Caleb, then the reigning sovereign of Axum, led an army into Arabia and subjugated the kingdom of Yemen. The reign of Caleb is described as the golden age of Abyssinian history, during which a high degree of internal and commercial prosperity was attained; but the Mohammedan invasion of Egypt in the 7th century checked the inflow of civilization from the outer world, and brought the progress of the country to a standstill. For nearly 1,000 years Ethiopia was isolated by the surrounding barriers of Islam. About 1492 Pedro de Covilham, who had been sent to the East by King JOHN II. of Portugal in search of the land of

Prester John, arrived at the court of Alexander, who then occupied the throne under the title of *negus* (king). On the death of Alexander, his successor, Negus David, was so young that his grandmother Helena acted for a while as regent, and through a mission to Portugal she secured the visit of an embassy from Lisbon to Abyssinia about 1520, an event which led to the subsequent active interference of the Portuguese in the affairs of the country. Estevan da Gama, the Portuguese viceroy in India and a grandson of the celebrated navigator, was ordered to aid the Abyssinians with a small armed force in their war against the Mohammedans of Adal, which had broken out about 1528, and had already lasted 12 years. Accordingly, in 1541, the first European military expedition into Abyssinia, numbering only 450 soldiers, with six cannon, landed at Massowa under the command of Cristoforo da Gama, the viceroy's brother. He defeated the Turkish forces under Mohammed Gran in many engagements, but finally

Abyssinian Warriors.

his army was routed and he was killed in an important battle fought in 1542, probably near the Senafe pass. At this period began the barbarian incursions of the Galla tribes from the south, which occasioned a long series of wars between the Abyssinians and the more savage but fairer invaders, who finally succeeded in establishing themselves on a strip of territory, which they still occupy, separating Shoa from the rest of the country. The Jesuits never wielded a paramount influence in the state except in the early part of the 17th century. The authority of the *negus* appears to have been maintained unimpaired until about the middle of the last century. The Gallas had by this time become of importance as prospective allies in intestinal quarrels; and to propitiate them, Yasous II. married a Galla woman. This act so incensed the native Christians that they practically withdrew their allegiance from the *negus*, who

lived but a few years after his marriage, and gave it to Ras Michael Suhul, the hereditary chief of Salowa in Tigré, who then became in fact the ruler of the country and governed it as long as he lived, although a nominal *negus* was placed upon the throne after the death of Yasous. It was during the administration of Ras Michael that the English traveller Bruce visited Gondar, in 1770. The authority of the *negus* had already become a nullity, the *ras*, who was ostensibly his minister, being in reality the ruler of the state. Soon the independent chiefs of the other provinces refused to acknowledge his sway. Shoa, Tigré, and Godjam, the S. W. province of Amhara, were virtually separate sovereignties for many years. A line of chiefs descended from a female representative of the ancient royal house ruled over Shoa; while Tigré was governed from 1790 to 1816 by Ras Walda Selassyé, who was visited at Antalo, his capital, in 1804, by Mr. Salt, the first Englishman to enter Abyssinia in an official character. Ras Ali of Amhara was the *de facto* governor of central Abyssinia from 1831 to 1855, although two princes, to whom he was minister, nominally ruled the country during this period. Between these dates the visits of numerous explorers made extensive additions to European knowledge of Abyssinia. In 1848 Mr. Walter Plowden, who had previously visited the court of Ras Ali at Debra Tabor in Tigré, was appointed British consul to Abyssinia. Lij Kasa, subsequently so famous as King Theodore, now appeared as an important character in Abyssinian politics. Born in 1818, he had been educated in a convent, as a scribe, whence a chance foray turned his thoughts to military affairs, and he became the leader of a predatory band of discontented soldiery, which grew to such dimensions as soon to be a power in the state. He then attacked the army of the mother of Ras Ali, who governed the district of Dembea for her son, and being successful was himself appointed to rule over it by the *ras*, who also bestowed upon the young chieftain the hand of his daughter in marriage. But this friendship was short-lived. Kasa recommenced war against his father-in-law, drove him from his dominions, subjugated the chief of Godjam and Dadjateh Ubyé of Tigré, and in 1855 found himself master of Abyssinia. He now caused the abuna to crown him king of the kings of Ethiopia under the name of Theodore. Plowden entered into official relations with the new government, and both he and his friend Bell, an Englishman in the emperor's service, resided in the country till 1860, when they were killed by insurgents. Up to this time Theodore had reigned tolerantly and with discretion; but the death of Bell and Plowden, to whom he was devotedly attached, together with the loss of his first wife, the daughter of Ras Ali, whose influence over him had always been excellent, wrought a great change in his character. His new wife, the daughter of a hos-

tile chief, in reality hated him, and henceforth he became morose, bloodthirsty, and tyrannical. Capt. Cameron, Plowden's successor in the consulate, arrived at Massowa in 1862 with presents from the queen for Theodore, which he delivered in October of that year. Theodore responded in a letter to the queen, proposing to send an embassy to England, which he transmitted through Capt. Cameron. To this the foreign office paid no attention, and the arrival of a messenger from England in 1864, with despatches for the consul but no answer to his letter, greatly incensed the king, who was already indignant at the refusal of the French government to recognize one M. Bardel, whom he had sent to Paris with a similar message to the emperor. In November, 1863, the German Scripture readers residing near the court and the missionaries in Dembea were thrown

into prison, heavily ironed; and on Jan. 4, 1864, Capt. Cameron and his suite were seized and placed in close confinement at Gondar, whence, after having been subjected to brutal tortures, all the captives were removed to Magdala. News of their imprisonment reached England in the spring, and a communication in response to his letter was at once despatched to Theodore in charge of Mr. Hormuzd Rassam, a Mesopotamian holding the office of assistant to the British political resident at Aden. He landed at Massowa on July 23, 1864, but owing to various obstacles did not succeed in delivering the letter to the king till Jan. 25, 1866. It induced Theodore to set the prisoners at liberty and to promise that they should meet Mr. Rassam near the N. W. extremity of Lake Tzana and travel with him to the coast. He was anxious, however, that Mr. Rassam should

The Burning of Magdala during the Attack by the British.

write to England for workmen and await their arrival in Abyssinia; and this desire not being acceded to, he remanded the captives to prison, accompanied by Mr. Rassam and his comrades, who were violently taken into custody at an audience held in the king's tent just prior to their intended departure. Theodore then dictated a letter to Lord Clarendon asking for military stores, workmen, and an instructor in artillery, and sent it to London by Mr. Flad, who reached that city on July 10, 1866. The other Europeans remained captives in Abyssinia. As a communication from the queen, forwarded by Mr. Flad, and demanding the release of the prisoners, met with no response, the British government determined to attempt their rescue by force. A military expedition was organized at Bombay, under the command of Sir Robert Napier, consisting of 4,000 British and 8,000

sepooy troops. Annesley bay having been chosen as a landing place, the army was debarked there, and in January, 1868, commenced the march to the interior through the Senafe pass, and proceeded southward toward Magdala, about 400 m. from the coast, whither Theodore had retreated, and where the European prisoners were confined. On April 9 the English force arrived in front of the fortress, and on the following day were attacked by the Abyssinians, whom they repulsed with a loss of 700 killed and 1,200 wounded, having themselves but 20 wounded. This engagement is known as the action at Arogi, and its result so discouraged the king that he immediately released all the captives. Magdala was stormed on April 13, and captured with a loss of 15 British wounded. As soon as the outer gate fell, Theodore, determined

not to be taken prisoner, placed the muzzle of his pistol in his mouth, fired, and fell instantly dead. The complete success of the undertaking led the government to raise Gen. Napier to the peerage, with the title of Lord Napier of Magdala. The departure of the expedition left the country in a state of anarchy. At the latest accounts a chief of Tigré named Kasa had succeeded in establishing his supremacy over a considerable region. He is said to be a weak man.—A tolerably complete bibliography of works relating to Abyssinia is given in Hotten's "Abyssinia and its People" (London, 1868). The more accessible English books on the subject comprise "Bruce's Travels," of which many editions have been published since the first in 1790; "The Highlands of Ethiopia," by Major W. C. Harris (London, 1844); "Life in Abyssinia," by Mansfield Parkyns (London, 1853); Hozier's "British Expedition to Abyssinia" and Markham's "Abyssinian Expedition" (London, 1869); and W. T. Blanford's "Geology and Zoology of Abyssinia" (London, 1870).

ABYSSINIAN CHURCH. According to the Chronicles of Axum, a work probably written by a Christian Abyssinian in the 4th century, the first apostle of Christianity in Abyssinia was the chamberlain of the Queen Candace of Ethiopia whose baptism is recorded in Acts vii. 27. But the actual origin of the Abyssinian church dates from about 316, when there landed on the coast of Abyssinia an exploring expedition sent out by Meropius of Tyre. Its members were all murdered except the two nephews of Meropius, Frumentius and Ædesius, who were presented to the king as slaves. After the death of the king, Frumentius became the instructor of the hereditary prince and actually regent of the country. When the prince became of age, Ædesius returned to Tyre; but Frumentius, who had previously organized the Roman and Greek merchants residing in Abyssinia into a Christian church, went to Alexandria and was consecrated by Athanasius bishop of Abyssinia. As the king himself with a large portion of the people was baptized, Axum soon became the see of a metropolitan (*abuna*), with seven suffragans. The emperor Constantine vainly endeavored to prevail upon Frumentius and the Abyssinian prince to adopt Arianism. When in the 5th and 6th centuries the Monophysites obtained control of the patriarchal see of Alexandria, the whole Abyssinian church joined this sect. In the 6th century the Monophysite priest Julianus spread Christianity in Nubia, which for several centuries was a wholly Christian country, until in the 16th century Mohanmedanism became predominant. Others of the sect gradually Christianized large tracts of the country. When the Portuguese in the 16th century opened a passage into the country, an attempt was made to bring about a union of the Abyssinian church with Rome. A Roman Catholic patriarch of Ethiopia was appointed, but his

efforts were unsuccessful. The Jesuit missionaries, who first established themselves in the country in 1555, succeeded in 1624 in inducing the heads of the church to submit to the pope; but the union lasted only a few years, and the subsequent labors of the Jesuits and the propaganda in this direction were equally fruitless. Since 1841 Roman Catholic missionaries of the order of Lazarists have renewed the effort to establish a union between the Abyssinian and the Roman churches, and in 1859 King Ubyé of Tigré sent an embassy to make his submission to the pope; but the hopes raised by this event were disappointed, though several villages have been gained for the Catholic church, and placed under a vicar apostolic. In 1830 the first Protestant missionaries, Gobat (subsequently Anglican bishop of Jerusalem) and Kugler, arrived in Abyssinia; they were soon followed by others, among whom Isenberg and Krapf have become best known. They obtained political influence, and in 1841 a pupil of the English Protestant mission school in Cairo, Andraos, was consecrated, under the name of Abba Salama, abuna of Abyssinia by the Coptic patriarch of Alexandria. Through him they hoped to gain the Abyssinian church for an evangelical reformation, and the hope was strengthened when a prince apparently devoted to them became, under the name of Theodore, ruler over all Abyssinia. But Theodore, when his power was fully established, banished or imprisoned the missionaries; and the abuna, who remained friendly to the Protestants, though he did not like to hear of conversions, died a prisoner in 1867.—Having always been Monophysitic, disputes about the nature of Christ have not torn the Abyssinian church into factions; but it is agitated by discussions on what are termed the several natiivities of Christ, of which the leading party at present reckons three. Recently controversies have arisen as to whether Christ possessed consciousness and a knowledge of good and evil while yet in the womb of the Virgin, and whether Christ is now equal or inferior to the Father in authority and power. But the most virulent dispute is whether the Virgin Mary is the mother of God, or only the mother of Jesus, and therefore whether she is entitled to equal honors with her Son. Circumcision is used in the Abyssinian church for both sexes, and precedes baptism. The Jewish sabbath is still observed as well as the Christian Sunday, and dancing still forms part of the ritual, as it did in the Jewish temple. Children are baptized by immersion and adults by copious affusion. The Nicene creed is used, the Apostles' being unknown. Communion is administered daily to the laity in both kinds. Confession is rigidly practised. Candidates for the priesthood must be able to read, to sing, and grow a beard, and they pay two pieces of rock salt as the price of being breathed upon by the abuna, and having the sign of the cross made over them. The orders

in church government are abuna, bishops (*komur*), alaka, who has charge of the revenues, and priests and deacons, who prepare the communion bread. The bishops now have only the duty of keeping the churches and church utensils sacred; the seven dioceses into which the church was formerly divided have become extinct. Priests and monks are very abundant. It requires 20 priests and deacons to do the full duties of one church. The numerous monks are all placed under the jurisdiction of the *etshege*, the superior of the convent Debra Libanos in Shoa. He ranks next to the abuna, and his authority is greatly respected in all matters of faith. He governs not only the numerous convents of his own order, but also those of the second order of the country, that of St. Eustathius. The most celebrated convents are Debra Libanos in Shoa, St. Stephen on Lake Haik in the Yesbu country, Debra Damo and Axum Thion in Tigré, and Lalibela in Lasta. The secular priests are, as in the other oriental churches, allowed to be once married, but the monks, take the vow of celibacy. The churches are small, and their walls are covered with hideous pictures of the Virgin Mary, the saints, the angels, and the devil. Each church has a *tabot* or ark of the covenant, on which its sanctity wholly depends; it contains a parchment bearing the name of the patron saint, and stands behind a curtain in the holy of holies, which only the alaka and the priest who consecrates the elements are allowed to enter. If a man has had four wives and outlives them all, he must go into a monastery or be excommunicated. The husband can break the marriage tie at any time by becoming a monk, and leave his wife to take care of the children. The priests have the power of granting divorces.—There is a version of the Bible in the ancient language of the empire of Axum, usually called the Ethiopian, but by the natives the Geez language. It was probably made from the Greek in the 4th or 5th century, and is still the only one used in the church services, though the ancient Ethiopian language is no longer spoken. The Ethiopian Bible contains all the books of the Roman Catholic canon, with several others, the best known of which is the book of Enoch. The total number of books is 81. A translation of the Old and New Testaments in the living Amharic language was made by Meeka, an Abyssinian, the companion of Bruce.—See Gobat, "Three Years' Residence in Abyssinia"; Isenberg's and Krapf's missionary journals in Abyssinia; Volz, *Die Christliche Kirche Ethiopiens* (in *Studien und Kritiken*, 1869, giving a review of all the information to be obtained from the recent literature on Abyssinia); Stanley, "The Eastern Church," pp. 96-99.

ACACIA, a genus of plants of the order *leguminosæ*, widely diffused over the tropical and sub-tropical regions of the earth; most abundant in Africa and Australia. They are trees

or shrubs, rarely herbs, with small, usually inconspicuous petals and sepals, but with many (10-400) long stamens, which give to the heads or spikes of flowers great beauty. The pods are two-valved, jointless and woody, containing seeds of which some species are edible. The leaves are either pinnate in various degrees, or simply distended leaf stalks (*phyllodia*). In nearly all the species the leaves are pinnate at first, and as the plant grows gradually give place to the phyllodia, often showing all gradations between the two forms. The stems and branches are often armed with spines. The acacias are not only most ornamental trees, with slender branches, delicate foliage, and attractive flowers, but the timber is often of great value, as that of *A. Arabica*, which is much used in India for wheels; and the *A. Koa* has a fine, hard, and variegated grain. The bark contains much tannin. *A. Vereck* yields gum Senegal, and *A. Nilotica* and *Seyal* gum arabic. Other valuable gums of a similar nature are obtained from other species. The flowers of *A. Farnesiana* yield by distillation a delicious perfume, much prized in the East. Many species are easily cultivated under glass. Little is known of the uses of most of the 420 species that have been described.

ACADEMY (Gr. *Ἀκαδημαῖα*), originally the name of a public pleasure ground situate in the Ceramicus (tile field), a suburb of Athens, on the Cephissus, said to have belonged in the time of the Trojan war to Academos, a local hero. In the 5th century B. C. this land belonged to Cimon the son of Miltiades, who beautified the grounds, gave free admission to the public, and at his death bequeathed them to his fellow citizens. They naturally became a favorite resort for all the loungers of the city, and Socrates was wont to hold forth in this delightful place. Plato taught his philosophy in its groves, and his school was hence named the Academic. As the Platonists were also called academists, so wherever an academist started a school, he called that school an academy. The word academy is used in English in two senses. In its unambitious acceptation it means a place of higher instruction for youths, ranking with the gymnasia of Germany. The name is also given to national military and naval high schools in England and America. But the word academy, in its larger acceptation, is employed to designate a society of learned men, established for the improvement of science, literature, or the arts. The first association of this sort recorded in history was called Musæon or Museum, and was founded in Alexandria by Ptolemy Soter, one of the generals and successors of Alexander the Great. This soldier, after he had got possession of Egypt, restricted his energies to maintaining a defensive balance of power and to the cultivation of letters and science. Gathering around him scholars of various attainments, he sought to attach them

permanently to his court by collecting books and treasures of art. Rome had no academies. The Alexandrian example, if lost upon the Romans, was imitated by the Jews in Palestine and Babylonia, and to a degree also by the Nestorian Christians. The Arabian caliphs profited by the lessons taught them by their Jewish and Christian subjects, and improved upon them by founding establishments for the preservation and increase of learning from Cordova to Samarcand. Charlemagne, following the suggestion of the learned Alcuin, encouraged men of culture to assemble in his palace; but after his death nothing was heard of academies until toward the end of the 13th and beginning of the 14th century, when institutions of the kind were established at Florence, Palermo, and Toulouse, chiefly devoted to the cultivation of poetry. It was not till after the downfall of the Byzantine empire in the 15th century, and the revival of classical culture in western Europe, that academies of a more comprehensive kind were established in Italy. The *Accademia Pontaniana*, so called after its principal benefactor Pontano, was founded at Palermo in 1433 by Antonio Beccadella. The *Accademia Platonica*, founded by Lorenzo de' Medici in 1474, lasted till 1521, counting among its members Machiavelli and other illustrious men, who devoted themselves to the study of Plato and of Dante, and to the improvement of the Italian language and letters. This institution became the model of many others. Rome had its Lincei, Naples its Ardent, Parma its Insensati, and Genoa its Addormentati. In other towns were the academies of the Confused, of the Unstable, of the Drowsy, the Dead, the Nocturnal, the Thunderers, the Smoky, and the Vagabonds. Most of these academies were endowed by the state or by some wealthy patron of learning. All those learned associations which are in point of fact academies, but which bear the name of societies, will be treated under that title. We shall now proceed to notice some of the most celebrated academies of the world, ranged according to their nationalities. **I. Italian Academies.** Italy is the mother country of modern academies. Jaceius, who in 1725 published at Leipsic an account of them, enumerates nearly 600 as then existing. We have already mentioned the first two; they did not live long. The most enduring and influential of all was the *Accademia della Crusca* (literally, academy of bran or chaff), so called in allusion to its chief object of purifying and winnowing the national tongue. It was founded in 1582 at Florence by the poet Grazzini. The dictionary of the Academy della Crusca was first published in 1612, and in its augmented form (Florence, 1729-'38) is considered the standard authority for the Italian language. The *Della Crusca* is now incorporated with two still older societies, and thus united they are called the royal Florentine academy. The *Accademia Secretorum Natura* was established

at Naples in 1560 for the cultivation of physical science, but was speedily abolished. This was succeeded by the *Accademia de' Lincei* (of the Lynx-eyed) at Rome, founded by Prince Federico Cesi in 1609, and dissolved after his death in 1632; but the name was revived in 1847 by Pius IX. in the *Accademia Pontificia de' nuovi Lincei*, a scientific association of resident and foreign members, which publishes its transactions. The *Accademia del Cimento*, or of experiment, was also instituted for the prosecution of inquiries in physical science, under the protection of Prince Leopold, brother of the grand duke of Tuscany. A collection of experiments was published in Italian by this academy in 1667, of which a Latin translation was made with valuable notes. The *Accademia degli Arcadi*, or of the Arcadians, at Rome, originated in 1690 from the social gatherings at the palace of Queen Christina of Sweden, and met in the open air, poets and poetesses only being admitted, and each member assuming the name of a shepherd. Its scope was afterward enlarged, and since 1726 it has met in summer in the Posco Parrasio of Mount Janiculum, in winter in the Serbatojo. It publishes a monthly collection of pieces, called the *Giornale Arcadico*, which frequently contains curious archeological information. Pope Leo XII. was elected a member in 1824, and Louis Napoleon, then president of the French republic, in 1850. At Naples the *Reale Accademia delle Scienze e Belle Lettere* was established in 1749, and the *Accademia Ercolanca* in 1755. The purpose of the latter was to explain the remains which were exhumed at Herculaneum and Pompeii. Its first volume appeared in 1775. Further volumes have since been published under the title of *Antichità di Ercolano*. Another existing academy is the *Accademia Etrusca* at Cortona, founded in 1726. The royal academy of Turin, in whose volumes of transactions Lagrange first made himself known, is chiefly remarkable on that account. Padua, Milan, Siena, Verona, Genoa, all have academies which publish transactions from time to time. The earliest academies of fine arts are also Italian. That of San Luca at Rome was established in 1593 by Federico Zuechero, who erected a building for it at his own expense. Academies of fine arts also exist in the principal cities of Italy. **II. French Academies.** The earliest and greatest of the French academies, the *Académie française*, was instituted in 1635 by Cardinal Richelieu, for the improvement and regulation of the national tongue. The number of its members was limited to 40. They met three times a week at the Louvre. The most remarkable claim of this academy to fame is the dictionary of the French language published in 1694, after 50 years consumed in debate upon the words to be inserted as good French. Many additions have been made to this in successive editions, the 6th and latest of which was published

in 1835. This academy was ridiculed by the French wits on account of its subservency to the court and its personal jealousies against rising men of genius. Molière, for instance, was passed over. Boileau and Labràyère were only elected on the absolute command of Louis XIV. The witty Piron wrote his epitaph thus:

Cligit Piron, qui ne fut rien,
Pas même académicien.

The *Académie française* survived until it was abolished by the republican convention in 1793. The next of the French academies in date is the *Académie de peinture et de sculpture*, which was founded in 1648, received letters patent from Mazarin in 1655, and was abolished by the convention in 1793. The *Académie royale des inscriptions et belles-lettres* was instituted by Colbert under the patronage of Louis XIV. in 1663. At first it was called the *Académie des inscriptions et médailles*, consisted of four members of the *Académie française*, and was charged with drawing up inscriptions for the monuments erected by Louis XIV. and for the medals struck in his honor. It was remodelled and enlarged under its present name in 1701, and temporarily suppressed in 1793. The *Académie royale des sciences* was the last in date. It was organized in 1666 and entirely remodelled in 1699. In 1795 all these academies were revived in a new form by the directory, under the name of *Institut national*. Napoleon gave it a new organization in 1803, and called it the imperial institute of France. Louis XVIII., at the restoration, maintained the name *Institut de France*, but revived the old title academy for the component parts of the institute. The institute consisted then of four academies: 1, *l'Académie française*; 2, *l'Académie des inscriptions et belles-lettres*; 3, *l'Académie des sciences*; 4, *l'Académie des beaux arts*. A fifth academy, *l'Académie des sciences morales et politiques*, founded in 1795, was suppressed at this time, but re-established in 1832. As these five academies are the most important of the kind in the world at present, we add a particular description of their constitution. The institute numbers 233 full members, together with 7 secretaries; each of the members has a yearly salary of 1,500 francs, and the secretaries have 6,000 francs each. There are also 43 honorary academicians, who receive no pay, 32 associates, and 215 correspondents. The five academies bear the same relation to the institute that colleges do to a university. The *Académie française* consists of 40 members, elected after personal application, and submission of their nomination to the head of the state. It meets twice a week, and is the highest authority on everything appertaining to the niceties of the French language, to grammar, rhetoric, and poetry, and the publication of the French classics. It distributes two annual prizes of 10,000 francs on the foundation of Count de Monthyon, one

to the author of the best work on public morals, the other to the individual of the working classes who in the course of the year has performed the most virtuous action; an annual prize of 2,000 francs on the foundation of Baron Gobert, for the most eloquent work on the history of France; and every second year a present of 1,500 francs to a poor rising genius who needs encouragement. This last is a bequest of the marquis Maillé-Latour Landry. The *Académie des inscriptions et belles-lettres* consists of 40 members, 10 honorary academicians, and 8 foreign associates; it has 50 corresponding members at home and abroad. It meets once a week. Its concern is with general history, the condition of peoples, laws, and manners, religious and philosophical systems; the study of chronology and geography, medals, inscriptions, and monuments of all sorts; and comparative philology, and explanation of ancient documents. This academy bestows a yearly prize of 2,000 francs for the best memoir contributed to its transactions, and another yearly prize for numismatics. It superintends the publication of the following works: *Mémoires de l'académie des inscriptions et belles-lettres*, the collection of the papers which have been sent to it by learned investigators; *Collection de notices et extraits des manuscrits de la bibliothèque royale et autres bibliothèques publiques*; *Mémoires sur les antiquités de la France*; the continuation of the *Histoire littéraire de France* begun by the Benedictines of St. Maur; the *Collection des histoires de France*; the collection of the *Histoires des croisades orientales, grecques et latines*; edition of the *Ordonnances des rois de France*, also begun by the Benedictines; collection of the charters and documents relating to the history of France, the letters of the kings of France, and the catalogue of the charters. The conduct of the *Journal des savants* devolves chiefly upon this academy, although every member of all the academies can contribute. The *Académie des sciences* numbers 63 members, 8 foreign associates, and 100 corresponding members. It bestows an annual prize of 3,000 francs for productions on natural science; three yearly prizes on Monthyon's foundation, for statistics, mechanics, and experimental physiology; a prize of 10,000 francs, founded by Lalande, for the most important astronomical discovery or observation, and another by the widow of the astronomer Laplace, for the best scholar of the polytechnic school. Many other rewards are in its gift, for scientific and industrial inventions, discoveries, and improvements. This academy publishes three series of *Mémoires*, and, what is peculiar, holds its sessions in public, which are much frequented by the residents of Paris. The *Académie des beaux arts* consists of 40 members, 10 honorary academicians, and 10 foreign associates. It meets once a week. It superintends the competitive examinations for the yearly prizes, in reward of the best achievements in paint-

ing, sculpture, architecture, engraving in copper, and musical composition. It has its memoirs and transactions, and is busied in the discussion of the *Dictionnaire général des beaux arts*. The *Académie des sciences morales et politiques* numbers 50 members, 5 foreign associates, and 40 corresponding members. Its five sections are: philosophy; moral philosophy; legislation, public law, and jurisprudence; political economy and statistics; and general history and philosophy. The whole institute has one regular session in common, on the 2d of May of each year. By an imperial decree of April, 1855, an annual prize of 10,000 francs is placed by the government at the disposal of the institute, for the most useful invention of the last five years.—Academies also exist in many of the provincial cities of France, as at Soissons since 1675, Nîmes (1682), Angers (1685), Lyons (1700), Bordeaux (1703), Caen (1705), Marseilles (1726), Rouen (1736), Dijon (1740), Montauban (1744), Amiens (1750), Toulouse (the first volume of whose transactions is dated 1782), and so on. There was also at Paris the *Académie celtique*, founded in 1807, for the elucidation of the history, customs, antiquities, manners, and monuments of the Celts, particularly in France; also for philological researches by means of the Breton, Welsh, and Erse dialects, and for investigation into Druidism. This is now merged in the *Société des antiquaires de France*, and has published several volumes of interesting memoirs. The French Opéra is styled the *Académie de musique*. **III. Spanish Academies.** A society for the cultivation of physical science, called the *Academia Naturæ Curiosorum*, was established at Madrid in 1652, on the model of the Neapolitan *Academia Secretorum Naturæ*, before described. Of those now existing, three are specially noteworthy, viz.: 1. The royal academy at Madrid, founded in 1714, on the model of the *Della Crusca* and the *Académie française*. It published the first edition of its dictionary in 1726-'39. 2. The royal academy of Spanish history. This commenced as a private association at Madrid, but was taken under royal protection in 1738. 3. The academy of painting and sculpture, at Madrid, dates from 1753. An academy of sciences was founded in 1847. **IV. Portuguese Academies.** An academy of Portuguese history was established at Lisbon in 1720, by King John V. A still more flourishing though more recent institution is the academy of science, agriculture, arts, commerce, and general economy, founded by Queen Maria in 1779. It is liberally endowed by the state, and is divided into three sections: 1, natural science; 2, mathematics; 3, Portuguese literature. The geographical academy at Lisbon has published a map of Portugal since the beginning of this century. **V. German Academies.** The royal academy of sciences and belles-lettres at Berlin was founded in 1700, by the elector Frederick, partly on the model

of the royal society of England, but not opened till 1711. Leibnitz was its first president. In 1744 Frederick the Great gave it a new organization; the king invited to Berlin many distinguished foreigners, and placed Maupertuis at the head of the institution. Formerly the transactions were published in French, but since the revolution they have appeared in German. A yearly medal worth 50 Prussian ducats is distributed. The other noteworthy German associations of the kind are the academies of Göttingen (founded in 1750), Munich (1759), Leipzig (1846), and Vienna (1846), chiefly devoted to historical studies and general scholarship. Prague, Cracow, and Pesth also possess creditable academies. **VI.** In Switzerland, there is an academy of medicine at Geneva, founded in 1715. **VII.** In Belgium, the academy of sciences and belles-lettres at Brussels was founded by Maria Theresa in 1772, suspended during the French revolution, revived in 1816, and reorganized in 1845 as the *Académie royale des sciences, des lettres et des beaux arts*. **VIII. Holland.** The *Academia Lugduno-Batava*, at Leyden, was founded June 18, 1766, and publishes *Annales*. The academy of Amsterdam, founded in 1808, was devoted to fine arts only, but was converted in 1852 into an academy of sciences, literature, and fine arts. Rotterdam, Haarlem, Utrecht, and Middelburg have also learned associations. **IX. Scandinavian Academies.** The royal academy of sciences at Stockholm was instituted by six men of science, among whom was Linnæus. Their first meeting was on June 2, 1739; in that year the first volume of memoirs appeared. On March 31, 1741, they were incorporated under the name of the royal Swedish academy. It is not supported by public patronage like the academies of France, Spain, Italy, and Germany. It has, however, a large fund, the fruit of legacies by private individuals. The transactions are written in the Swedish language, but have also been translated into German. Annual premiums for the encouragement of agriculture and inland trade are distributed by the academy. The prize fund is indebted for its existence to voluntary contributions. Stockholm contains also an academy of belles-lettres, established in 1753; and the literary academy of Sweden, founded in 1786, whose object is the cultivation of the national language. There is an academy of northern antiquities at Upsal, whose researches have done much toward elucidating the early condition and creeds of the Gothic race. The royal academy of sciences at Copenhagen owes its origin to six individuals. The count of Holstein was its first president, and the king of Denmark extended to it his patronage in 1743. It has published 15 volumes in the Danish language, which have been in part translated into Latin. The academy of the fine arts was established in 1733 at Stockholm, by the exertions of Charles Gustavus, count of Tessin; and that of Copenhagen, founded in 1738,

was incorporated in 1754. **X. Russian Academies.** The imperial academy of sciences at St. Petersburg was projected by Peter the Great. He took the advice of Wolf and Leibnitz. Learned foreigners were invited to become members. The death of Peter left the execution of this project to his successor, Catharine I. The academy held its first sessions in December, 1725. A large annual sum was appropriated for the support of the members. The most distinguished of the professors were Bulfinger, a German naturalist, Nicolas and Daniel Bernoulli, Wolf, and the two De Lisle. The academy suffered many vicissitudes until the accession of the empress Elizabeth in 1741, when new life was infused into it. The first transactions of this academy were published in 1728, and entitled *Commentarii Academicæ Scientiarum Imperialis Petropolitane ad Annum 1726*, with a dedication to Peter II. Until 1777 the papers were published in the Latin language only; they are now written sometimes in French and sometimes in German. Several volumes are published every year. Each professor has a house and an annual stipend of from \$1,000 to \$3,000. The celebrated mathematician Euler contributed largely to the mathematical papers of this body. In 1783 an institution on the model of the *Académie française* was established at St. Petersburg, for the cultivation of the national language, but it was soon amalgamated with the imperial academy. The *Académie impériale des beaux arts* of St. Petersburg was founded in 1765 by Catharine II., who endowed it richly. It now sends out pupils to Germany and Italy for education in the fine arts, and supports them during their studies. Mr. Albert Bierstadt, chosen in 1871, was the first American honorary member of this academy. **XI. British and Irish Academies.** In Britain proper, the term society or association is the designation in use for bodies of learned men united in pursuit of some common object. They will be found enumerated under the head of SOCIETIES. The word academy in Britain is reserved for institutions devoted to the cultivation of the fine arts. In Ireland the continental name has been adopted. The royal Irish academy, founded in 1782, at Dublin, has published transactions from time to time since 1788. The present royal academy of arts in London originated in a society of painters, who obtained a charter in 1765, under the title of the "Incorporated Society of Artists of Great Britain." This society took a new form in 1768, and became the royal academy of arts. It consists of 40 artists, bearing the title of royal academicians, of 18 associates, 6 associate engravers, and 3 or 4 honorary members. There is an annual exhibition of paintings, sculptures, and designs, open to all artists. This exhibition is so well frequented that the royal academy draws almost all its funds from the money paid by the public for tickets of entry. The Edinburgh royal academy of paint-

ing was founded in 1754. A similar institution, called the royal Hibernian academy, was established in Dublin about 1832. An academy of ancient music was established in London so early as the year 1710; but a disagreement among its members finally broke it up. Soon afterward the royal academy of music was formed for the performance of operas composed by Handel. Another disagreement broke this up in 1729. The present royal academy of music was established in 1822. It is of great utility as a school of vocal and instrumental music. **XII. Turkish Empire.** The academy established in 1851 at Constantinople is still feeble. That founded at Alexandria in 1859 has published memoirs and bulletins since 1862. **XIII.** The principal Australian academy is located at Victoria. **XIV. Asia.** There are learned associations in all the important British colonies of Asia, and an academy at Batavia (Java), devoted to sciences. **XV. American Academies.** In America, as in Britain, the term academy is not generally used for learned societies. The American academy of arts and sciences, at Boston, founded in 1780, has published several volumes of transactions. The Connecticut academy of arts and sciences was founded in 1799. The academy of natural science, at Philadelphia, founded in 1818, is a flourishing institution, and has splendid collections of fossils, stuffed animals, birds, and Dr. Morton's collection of skulls, the finest on the American continent. The national academy of sciences was incorporated by congress March 3, 1863. It is provided that "the academy shall consist of not more than 50 ordinary members, shall have power to make its own organization, including its constitution, by-laws, and rules and regulations; to provide for the election of foreign and domestic members, the division into classes, and all other matters needful or useful in such institution, and to report the same to congress." Fifty members were named in the original act, a majority of whom met for organization in New York, April 22, 1863. The academy receives no support from the government, and, being destitute of funds beyond a legacy left by the late Alexander Dallas Bache, is not in condition to publish its proceedings; hence the public hear very little of its activity. The Pennsylvania academy of fine arts, established in 1807, holds annual exhibitions at Philadelphia. The national academy of design, at New York, was founded in 1828, chiefly by the exertions of Mr. S. F. B. Morse, its first president. It is composed exclusively of artists, has one of the most conspicuous buildings in the city, maintains a flourishing school of design, and has annual exhibitions. The medical academy of New York is in a flourishing condition; its meetings are well attended, and attract much public interest. New York, following the Parisian example, called her principal opera house the academy of music. This spacious building, erected by an incorporated

society, and capable of containing 4,500 persons, was opened in the autumn of 1854; it was burned in 1867, and replaced by one of considerably smaller dimensions. Philadelphia followed with a similar construction for similar purposes; it was inaugurated as the American academy of music in the winter of 1856-7. Other opera houses with the same designation have since been erected in Brooklyn, Chicago (burned in 1871), and other cities. **XVI.** At Rio Janeiro and in other South American capitals are also academies of learning and of fine arts.

ACADIA, or *Acadie*, the name of the peninsula now called Nova Scotia, from its first settlement by the French in 1604 till its final cession to the English in 1713. In the original commission of the king of France, New Brunswick and a part of Maine were included in Cadie, but practically the colony was restricted to the peninsula. The English claimed the territory by right of discovery. In 1621 it was granted by royal charter under the name of Nova Scotia, and its possession was obstinately disputed. (See *NOVA SCOTIA*.) The quarrels between the two nations were embittered by the desire for exclusive possession of the fisheries. After the final cession the Acadians generally remained in Nova Scotia, though they had the privilege of leaving within two years, and, refusing to take the oath of allegiance, took the oath of fidelity to the British king. They were exempted from bearing arms against their countrymen, whence they were known in the colonies as the neutral French. They were allowed to enjoy their religion, and to have magistrates of their own selection. The French, having lost Acadia, settled the island of Cape Breton and built Louisburg. There they carried on intrigues with the Indians, who kept up an irregular warfare with the English, the blame whereof was thrown upon the neutral French, who in 1755, a few years after the English turned their attention to the colonization of Nova Scotia, suffered for the offences of their countrymen, of which they were doubtless innocent, since they were a simple agricultural people. Because they still refused to take the oath of allegiance, or to bear arms against the French or their Indian allies, to whom they were suspected of lending aid, and because by their peculiar position they embarrassed the local government, it was determined at a consultation of the governor and his council to remove this whole people, 18,000 souls, and disperse them among the other British provinces. For this harsh measure itself there may have been some excuse; for the manner in which it was carried out there was none. The inhabitants were compelled to give up all their property, their houses and crops were burned before their eyes, and themselves shipped in such haste that few families or friends remained together. In a few towns the Acadians discovered and escaped the plot, but most of them were scattered over the continent.

ACALEPHE (Gr. *ακαληφη*, nettle), a class of animals living in sea water, some species of which possess the nettle-like property of irritating and inflaming the skin. The animals are invertebrate, gelatinous, of circular form, often shaped like an umbrella, and all included in the division of *radiata*. (See *JELLY FISIL*.)

ACANTHUS. Under this name have been described by the classical writers three different plants: 1. A prickly tree, with smooth evergreen leaves and saffron-colored berries, believed to be the common holly. 2. A prickly Egyptian tree, with a pod like a bean, supposed to be the *acacia Arabica*, or gum arabic tree. 3. An herb with broad prickly leaves, which dies in the winter, but shoots out afresh in the spring. The idea of the beautiful Corinthian capitals of the Greek columns is said to have been derived from a basket filled with the roots of this plant, set down carelessly by a girl, and covered with a tile; when the leaves, forcing their way through the crevices, and rising toward the light, until met by the under side of the cover, presented the effect of the foliage and volutes simulated by the Grecian chisel. In modern botany *acanthus*

Acanthus mollis.

is a genus of herbaceous plants found in the south of Europe, Asia Minor, and India, the commonest species of which is the *acanthus mollis*, a native of moist, shady places in the south of Europe. It has pretty foliage and large white flowers tinged with pale yellow. This was long supposed to be the classic plant of antiquity; but it has been shown that it does not exist either in the Peloponnesus or in the isles of Greece, and the honor of having furnished the idea of the Corinthian capital is now attributed to the *acanthus spinosus*, which has deeply cleft prickly leaves, and flowers tinged with pink instead of yellow. In England they are both half-hardy perennials, needing protection from frost, and propagated by subdivision of the roots. In America they would probably endure the winter south of Maryland; northward they would be greenhouse plants.—The word *acanthus* also signifies thorn, as in *acanthopterygius*, thorny-finned, applied to an order of fishes.

ACAPULCO, a seaport town of Mexico, on the Pacific, in the state of Guerrero, 180 m. S. by W. of Mexico; lat. 16° 50' N., lon. 99° 48' W.; pop. about 4,000. It has one of the best

harbors on the W. coast, and during the Spanish dominion in Mexico was the focus of the trade from China and the East Indies, and a place of considerable importance. It has since relapsed into insignificance, although previous to the opening of the Pacific railroad the California trade imbued it with a transitory commercial life, in consequence of its having been made the coaling station for the steamers between Panama and San Francisco.

ACARNANIA, a province of ancient Greece, bounded N. by the Ambracian gulf and Amphiloehia, which is by some included in Acarnania, E. by Ætolia, and S. W. and W. by the Ionian sea. It is mountainous, with numerous lakes and tracts of pasture, and its hills are still well wooded. Among its earliest inhabitants were Leleges, Curetes, and colonists from Argos. The Acarnanians were more akin in character and manners to their savage neighbors of Epirus than to the Greeks proper. Up to the time of the Peloponnesian war they were a race of shepherds, continually fighting, but faithful and steadfast. They also figure as pirates. Though possessing several good harbors, the Acarnanians paid little attention to commercial pursuits.—At the present day it forms with Ætolia a nomarchy or province of the kingdom of Greece; area, 3,024 sq. m.; pop. in 1870, 121,693. The country is thinly inhabited, and little cultivated, notwithstanding its fertile soil and treasures of sulphur and coal. Besides the Greek population, there are bands of nomadic Kutzo-Walachs, here called Karagunis (black cloaks), who in the winter descend from the northern mountains of Agraphi and encamp with their herds at the edge of the woods. They speak a dialect akin to the Latin. Different from them are the nomadic Sarakatzanes, who are of Greek origin. A band of the Karagunis embraces from 50 to 100 families, constituting a *stani*, and is commanded by the most wealthy member as chief (*tchelinga*), who farms the pastures and fixes the time of departure. They are skilled in making cotton goods. Capital, Missolonghi.

ACARUS, the name of a genus of insects, commonly called mites. They belong to the spider family. They are all extremely minute, and mostly microscopic insects. Some are parasitic, as the itch insect, *acarus scabiei*. The different species infest brown sugars, meal, cheese, &c. To collections of insects and stuffed birds they do much injury. Camphor tends to keep them off, and corrosive sublimate is a still more effectual protection. (See EPIZOA, and IRU.)

ACASTUS, in mythology, son of Pelias, king of Iolcus. He took part in the Calydonian hunt and the expedition of the Argonauts. He revenged the murder of his father, in which his sisters were the instruments of Medea, by driving Jason and Medea out of Iolcus, and instituted funeral games in honor of Pelias.

ACCAD, one of the four cities in the "land of Shinar" or Babylonia, which, according to Gen. x. 10, were the beginning of Nimrod's kingdom. Among other places, it has been identified with Nisibis. Rawlinson sees in Accad the name of "the great primitive Hamite race" in Babylonia.

ACCELERATION, an increase in velocity of a moving body, either constant and uniform or variable. When the velocity receives equal increments in equal times, it is uniform. This is the case with bodies falling in a vacuum, the increase of which is in every second about $32\frac{1}{2}$ feet, but varies with the latitude of the place and the height above the ocean, or the depth under the surface of the earth. As gravitation is the cause of this acceleration, scientists have accepted the letter *g* for it as a symbol, meaning 31 or 32 or any other number of feet, as the case may be. At the distance of the moon the acceleration is 3,600 times smaller, and *g* is thus equal to about $\frac{1}{3}$ inch; while at the surface of the sun and large planets it is much greater by reason of the greater attraction of large masses. Acceleration is variable when its velocity increases at one instant in a greater or lesser ratio than in another. This is the case with a body falling from a great height toward the earth through the air; the resistance of the latter increasing with the velocity, the ratio of increase must diminish till the accelerating force, that is, gravitation (*g*), balances the resistance of the air, when the body will continue to fall with uniform motion, which motion may then become retarded if the body in its downward course enters strata of air of greater density and thus at greater resistance. The motions of the planets, and especially of the comets, in their orbits around the sun, offer other illustrations of variable acceleration.—**Acceleration of the Moon.** Halley noticed that the comparison of ancient eclipses with modern shows that the moon moves faster now than formerly, and the solution of the problem as to the cause of this acceleration was first given by Laplace, who showed that the slow diminution of the eccentricity of the earth's orbit must produce an acceleration of the moon's motion and a decrease in the period of its revolution. Adams has recently shown that Laplace overestimated the effect of the change of the earth's orbit on the moon by one half, and that his demonstration therefore only accounts for half of the moon's acceleration. The cause of the other half remains to be found out. Delaunay ascribes it to a retardation in the earth's motion of rotation by the influence of the tidal wave raised by the moon, and reacting on the latter. The earth's daily rotation, however, appears to undergo neither acceleration nor retardation; therefore others ascribe it to a resisting medium, filling the interplanetary space and revolving round the sun with the planets, and which thus only can affect their moons, which at every half revolution move

in opposite direction to the general motion, and thus having their centrifugal force checked are drawn nearer to the planet, by which their apparent or angular velocity is increased.—**Acceleration of the Stars.** The so-called stellar acceleration is no acceleration in the true sense, but means only the amount that the apparent daily revolution of the stars gains on that of the sun. It is easily calculated by considering the fact that the starry heavens make per year one revolution more than the sun; therefore the daily gain must be $\frac{1}{365}$ part of 24 hours, which is very near 3 minutes and 56 seconds.

ACCEPTANCE, an agreement to pay a bill when due according to the tenor of the obligation assumed. A bill of exchange or draft is a written instrument by which A requests B to pay C a sum of money at a certain time, unconditionally. A is the drawer, C the payee, and B the drawee; and if B assents to the request, or in other words accepts the bill, he is the acceptor, and his agreement is the acceptance. The bill is usually drawn on the drawee B because he has funds of A in his hands, or is indebted to him to the amount covered by the bill. But the bill does not ordinarily of itself work an assignment of the fund or the debt so that C can claim that specifically of B. An order drawn on B for the payment to C of any particular fund amounts to an assignment of that fund, and B is bound by mere notice of the order to make the payment, and his acceptance or assent to the arrangement is not essential. But a bill of exchange is not an assignment of nor an order on any special fund, but is intended to raise a contract by the drawee which he may satisfy out of any money which he has. This contract, however, does not arise, and the drawee owes no duty to the payee of the bill, until he accepts it. It is therefore the duty of the holder to present the bill for acceptance. This is fairly implied from the form of the instrument; and if the acceptor is not called upon, as the bill directs that he shall be, and then fails, the drawer will be discharged. In some countries, as for example in France, acceptance must be demanded within limits defined by positive laws. But by our law, though there is no fixed time prescribed within which the presentation for acceptance must be made, it ought obviously to be within a reasonable time, considering all the circumstances. What is or is not such a reasonable time is a question of law, and depends, for example, upon the character of the bill, whether payable a certain time after sight, or at a precise date, or whether domestic or foreign; upon the place where it is drawn regarded in connection with the place on which it is drawn; or upon the legitimate commercial negotiation or use which may be made of the bill. If the bill is payable at sight, or so many days or months after sight or after demand, the presentation is necessary in order to fix the time of payment, and it ought to be made with diligence; though if it is payable at a

fixed period after its date, or at a day certain, the holder need not offer it for acceptance until its maturity. Again, what is reasonable time for presentation in the case of a bill drawn in Boston on New York would not be reasonable time in case of one drawn in New York on Calcutta. So delay to present the bill may be excused when an inevitable accident prevents the holder from doing it, such as his illness, or the outbreak of a war which forbids commercial intercourse. The usual course of negotiation of the bill may also justifiably delay its presentation for acceptance, so that what would be reasonable time in the case of a negotiated bill would be unreasonable in the case of one which had never been yet transferred. The principle of the rules respecting presentation for acceptance being that the drawer and other parties may be injured by delaying it, an entire omission to present the bill to the acceptor may be excused when it appears that the drawer had no funds in his hands and had no right to suppose that he had, or when for any other reason it is certain that the omission was not prejudicial to the drawer or other parties. In certain cases no acceptance and therefore no presentation is necessary to charge the drawee; as where a bill is drawn by a person upon himself, or by a partner upon his firm, or by one officer of a corporation on another officer of it or on the corporation itself.—When the bill is addressed to the drawee at a particular place, the demand for acceptance should be made at that place; and if the drawee, though not at the very place named, is within the same town, and perhaps within the same state, he should be sought out. But if he never lived in the place named, or has removed to a distant place, especially if it is out of the state, or his house is shut up and no one is there to answer for him, presentation is excused and the bill may be treated as dishonored. When the bill is drawn on a firm, it is enough to present it to one of the partners. If the presentation is required by the bill to be made at a bank, it must be made within the usual bank hours; or if at the drawee's place of business, then within the usual hours of business; but if it is to be made at his home, it may be made within any reasonable hours of the day; and in all cases the drawee is entitled to have possession of the bill for a day if he require it, in order to decide, on examining his accounts with the drawer, whether to accept or not.—The acceptance may be absolute or qualified or conditional, though the holder is not bound to receive anything but an absolute acceptance. It may be written, or, if no statute interferes, it may be oral. It may be before the drawing of the bill or after it is drawn, or even after its maturity; and it may be by the drawee, or by some one else, for honor of the drawer or other parties to the paper. But the acceptance is usually absolute, in writing, and on the bill itself; and any form is sufficient which indicates the purpose of the drawee to honor the

draft. The usual forms are, "Accepted" or "Honored," or the mere signature of the acceptor written across the face of the bill. In New York, by special statute, the holder may require that the acceptance be written on the bill, and a refusal to comply with such request may be regarded as a refusal to accept, and the bill may be protested for non-acceptance. By the same statute, if the drawee receives the bill and then destroys it, or refuses to return it within 24 hours, accepted or not accepted, he is deemed to have accepted it. This is only a positive enactment of a rule, the principle at least of which is pretty firmly established in the general commercial law. For, though the detention of a bill is not essentially an acceptance of it, yet when it takes place under such circumstances as fairly justify the holder in supposing that an acceptance is intended, or if any other construction of the drawee's act would prejudice the holder without any fault on his part, it is fair enough to fix upon the former the same liability which he would have incurred by an actual acceptance.—The acceptance may be qualified or conditional; as for a part of the amount which the draft calls for; or to pay at a different time or place, or in a different manner from that required; or when the drawee is in funds, or when certain goods in his hands are sold. If the holder accepts any of these variations from the tenor of the bill, he is bound by them. But, as already said, he cannot safely assent to them if they are at all substantial variations, unless he has the consent of the other parties; for their liability is founded on the very terms of the instrument, and they are not bound by any new conditions which the acceptor may propose, unless they expressly agree to them.—The acceptance need not be in writing unless positive statutes require it. But for the purpose of preventing the inconveniences which result from an opposite rule, there are in many of the states positive statutes to that effect, and the best illustration of them is furnished by the statute of New York. It is provided there that no person shall be charged as an acceptor on a bill unless his acceptance is in writing and signed by him-self or his lawful agent. But it is also provided for the benefit of a drawer, that this and the other provisions of the act shall not impair any of his rights against a drawee, on the faith of whose promise to accept the bill the drawer drew and negotiated it. By the same statute it is declared, as indeed it is well established by the general commercial law, that any unconditional promise in writing to accept a bill, though made before it is drawn, amounts to an actual acceptance of the bill in favor of any person who took the bill for valuable consideration on the faith of such promise in writing. Neither of these last rules of the statute, it will be seen, takes away or affects at all a drawer's undoubted right to damages against a drawee for breach of an agreement, made on good consideration with

the drawer, to accept his bills. Under the last cited provision of the statute it has been held in New York that an unqualified authority in writing or by telegraph to draw on one is equivalent to his unconditional promise to accept the bill drawn; and that a letter of credit which confers an absolute authority on the holder to draw bills upon the author of the letter is also an unconditional promise in writing to accept the bills drawn, within the same section of the statute; and in both cases the liability is enforced in favor of the persons who took the bills on the faith of the written authority. With the qualification, perhaps necessary, that the written promise to accept, or authority to draw be given within a reasonable time before or after the date of the bill, or contemplate or in some way fairly include the bills actually drawn, the rule or principle just stated is the general rule of the law.—If the original drawee refuses to accept or cannot be found, and the bill has been duly protested, any other person may accept for honor, or, as it is sometimes said, *supra* protest. It may be for the honor of the drawer or an indorser, or for the honor of the bill generally; and if it is intended to be for the benefit of any one especially, the acceptance ought to point him out. It is a conditional agreement by a volunteer to pay the bill at maturity if the original drawee does not. When one has paid a bill for the honor of the drawer, for example, he may recover against him after proving presentation to the original drawee, non-acceptance or non-payment by him, and notice to the drawer; in short, by doing just what the payee must have done to sustain an action. This rule of the commercial law is well established, though it is utterly anomalous, and forms perhaps the only exception to the principle that no one can make another his debtor without his consent. The holder of a bill is of course not bound to receive such an acceptance; but if he does, he is bound to conform to the new condition of things, so that in order to hold the acceptor for honor he must call on the original drawee before applying to him; and if he wishes to hold the drawee or other party, to whose benefit the acceptance for honor accrues in case of non-payment by the acceptor for honor, he must not only call on the original drawee, but also on the acceptor for honor, protest in both cases, and notify the prior parties.—Every acceptance admits the signature of the drawer; so that an acceptor is liable to an innocent holder for value even though the drawer's signature is forged. So also the acceptor admits the authority of one who has drawn as the agent of another.—In case of non-acceptance of a bill, the holder is bound to give notice of the fact to the drawer or indorsers if he wishes to hold them. Mere failure to notify them will not be fatal to the holder's action against them, if he can show that they have sustained no injury from his omission; but the presumption

of injury is in their favor, and the burden of proof is on him to overset it. The mere fact that the drawer had no funds in the hands of the drawee is probably not sufficient excuse for failure to give him notice of the dishonor of the paper. Perhaps he ought to have had funds if the drawee had kept his account properly, or at all events he may be prejudiced in some way by want of notice, and it is not safe to assume anything against his right to have it, in case of non-acceptance. Foreign bills should be protested in full form. It is customary to protest as to inland bills also, but it is not necessary, unless positive statutes require it. Indeed, where they do not require or authorize it, protest of inland bills is an empty form, of no use whatever.

ACCESSORY, properly, with reference to a felony, one who takes part in the act, but not such part as to be a principal. The law recognizes no accessory in treason, the highest of crimes, nor in misdemeanors, the lowest class of offences; in the former case, because the crime is so great that it will hold all participants equally guilty; and in the latter case, because the crime is comparatively so small that it will not trouble itself to distinguish between the degrees of guilt. In offences of these degrees all are principals. Accessories are familiarly designated as those before the fact and those after the fact. An accessory before the fact is one who participates in the very criminal act of the principal; but an accessory after the fact is guilty of a crime of his own, which is independent of that of the principal, and in which the latter properly has no share. To call him an accessory, therefore, is not quite accurate; at least the word has not the same propriety of meaning that it has when applied to the accessory before the fact. But the description is fixed in the law and cannot be disturbed.—When a crime is committed, he who actually does the specified act is the principal, and, as it is said sometimes, he is the principal in the first degree; and he who is present, and aids and abets the principal in doing the act, is called the principal in the second degree. But he who, though not present at the commission of the act of the principal, yet commands, counsels, or procures it to be done by him, is an accessory before the fact. Here absence is essential; for the same act of instigation and procurement, if done in the presence of the actual offender, and at his perpetration of the offence, would make the participant a principal. Thus in the case of a murder, those who are present, and intelligently aid and abet the killing, are all principals. But if two men meet in the presence of others and fall to blows, and either have a deliberate, malicious intent to kill the other, but the by-standers, being ignorant of this, aid and abet the fighting merely, they are not guilty of murder if one be killed. But again, as to presence, there may be a constructive presence as well as an

actual presence; so that mere physical absence from the scene of the offence will not necessarily save the participant from the guilt of a principal and make him a mere accessory. Thus he is a principal who conspires with a murderer for the doing of the act, but stands at a distance and is absent from it in order to watch against surprise or discovery, or to prevent the escape of the victim. But if A simply command B to beat C, and he does beat him so that he dies, B is the principal in the murder and A is the accessory before the fact. If A, however, command B to commit a certain crime, and B, of his own will and design, commit a different one, A is not an accessory to the offence committed, because he is not guilty of setting in motion the criminal intent which executed the act. But it will be otherwise if B, in attempting to execute A's design, execute it on the wrong person; for in that case A is guilty of setting in motion the very criminal intent which resulted in the crime actually committed.—In an old phrase of the law the accessory is said to attend and follow the principal, as the shadow does the substance; and at common law, and where no statutes have intervened to change the rules on this subject, the accessory cannot be guilty of any other, and at all events of no higher offence than his principal; nor is he guilty at all if his principal is not guilty; if the principal is acquitted, so is the accessory; he cannot be convicted, except jointly with the principal, or after his conviction; and formerly, and until a remedial statute to the contrary, if after conviction of the principal sentence upon him was stayed for any reason, the accessory could not be held. But recent statutes in England and in almost all of the United States have very materially changed the law in these respects. For example, the statutes of Massachusetts and New York provide that any person who, by counselling, hiring, or otherwise procuring the commission of a felony, becomes an accessory before the fact, shall be punished in the same manner as the principal felon. In New York it is also provided that the accessory before or after the fact may be indicted, tried, convicted, and punished, notwithstanding that the principal felon has been pardoned or otherwise discharged before conviction; and in Massachusetts, if for any reason the principal is not amenable to justice. In that state, too, the aider and abettor, who at common law would have been but a mere accessory, may be indicted and convicted of a substantive felony, without any regard to the indictment or conviction of the principal. There are similar statutory provisions in Pennsylvania; and, indeed, probably all the states have statutes of the same character.—An accessory after the fact is one who, knowing the guilt of the felon, whether principal or accessory before the fact, receives or assists him, but, it should probably be added, with intent to hinder his trial, conviction, or punishment;

as, for example, by concealing him or shutting out the officers of the law, or resisting them, or attempting to take him or rescuing him from their custody, or providing him with money or other means of flight, or bribing a jailer to permit his escape from prison. But merely suffering the felon to escape, or simply ministering to his physical necessities, will not make one an accessory after the fact. At common law the guilt of assisting the felon in these unlawful ways was not excused even to those of his own family, so that a father might not thus protect his son, nor the son his father, nor a brother his brother, nor a husband his wife. The single exception was in favor of the wife who sought thus to save her husband, and probably this was on the ground, in part at least, that she was supposed to be under the control of her husband, and to have no choice to do otherwise. But in this respect the modern statutory law has interposed benignantly. In Massachusetts, for example, it exempts those who stand in the relation of parent or grandparent, child or grandchild, brother or sister to the offender; and there are similar statutes in other states.

ACCLIMATION, or **Aclimatization**, the process by which an individual or a species, on being removed to a different climate, becomes modified in constitution and adapted to the changed conditions. The two words, however, are not strictly synonymous. Aclimation is generally used in speaking of particular individuals, and more especially of those belonging to the human species, and refers to the alterations which the system undergoes spontaneously in a foreign climate, by which it at last becomes no longer subject to the maladies peculiar to new-comers. Aclimatization, on the contrary, expresses the artificial care by which man succeeds in naturalizing, under his own supervision, a species of animals or vegetables of exotic origin.—**Aclimation**. Man inhabits all the zones and nearly every region of the earth, and has been enabled in repeated migrations to change the place of his habitation and to occupy new countries. The human species is therefore regarded as cosmopolitan; and yet two facts are important to notice in this respect: First, most of the great migrations, historic or traditional, have been made in the direction of longitude and not in that of latitude; the migrating tribes instinctively or intentionally keeping nearly within the same parallels of latitude, and consequently not suffering very great alterations of temperature, nor meeting in their new homes with a flora and fauna very dissimilar to those of their native country. Secondly, at the present day, although an individual may migrate either westward or eastward, as a general rule, without suffering from the change, a removal into a different latitude is almost always accompanied with peculiar dangers during the first few years of his residence in the new locality. The most marked instance of

this kind is when a person from the temperate zone visits for the first time a tropical or sub-tropical region. The dangers that first beset him are fevers, which are so marked in type and so ready to attack newly arrived immigrants, that they are sometimes called the "strangers' fever." The yellow fever of the West Indies and the southern United States, and the coast fever of western Africa, are well known examples of these affections. They are not absolutely restricted to new-comers, the natives being also subject to them; but the recent immigrant is so much more likely to be affected, and is attacked by the disease in so much larger proportion, it is evident that his system has in it something which offers a peculiar attraction for the febrile poison, and which does not exist, at least to the same extent, in that of the native or the old resident. After passing through a period of general ill health and debility, extending over some years, and perhaps one or more severe attacks of illness, the immigrant approximates in his appearance and habit of body to the older denizens of the place, and is no longer peculiarly liable to the disorders which affected him on his arrival. He is then said to be acclimated. No doubt, part of the immunity enjoyed by old settlers in a tropical or sub-tropical climate is due to the fact that they have learned prudence in regard to exposure, and have come to regulate habitually their mode of life to correspond with the climate of the country. Recent immigrants often neglect these essential precautions, because they have not found them necessary in a temperate climate; and it is only after repeated experience of their value that they come to adopt them habitually and as a constant protection.—**Aclimatization**. Many of the useful animals and plants have been successfully transferred from their original locality and made to thrive in new and unaccustomed places. The horse, the ass, the ox, the sheep, the goat, and the cat have accompanied man nearly everywhere within the temperate and tropical regions, and the dog is his companion even within the arctic circle. This fact has given rise to the hope that acclimatization might be successfully extended to still other species, and the *société d'acclimatation* at Paris has been established with a view of experimental investigation in this direction. Their endeavors have in many instances proved successful, at least in so far that tropical animals are found, when well cared for, to support the cold of a European winter without injury or even inconvenience. The zebra from Africa may be seen quietly resting upon the snow, and the tapir from Guiana swimming for his amusement in the stream which runs through his enclosure, when the temperature of the water is hardly above the freezing point. This, however, by no means indicates a completely successful acclimatization. It is successful so far as the individual is concerned; but acclimatization means the survival and prosperity of the spe-

cies. In order to secure this result, the animals which have been imported must themselves thrive and reach their usual term of existence, and produce offspring; the parent must willingly take the natural care of her young; the young animals must themselves have sufficient vigor to arrive at maturity and again reproduce their kind. Either one of these conditions may fail, and in certain instances have done so, notwithstanding that all the preceding ones had fully succeeded. Finally, in order that acclimatization may be in any case practically useful, the animals of the naturalized species must, in addition, be able in their new habitation to bear the labors or produce the material for the sake of which man has taken them under his care. Plants may be acclimatized to a certain extent, and if slowly accustomed to a change of climate, and well cared for, they will in their offspring undergo changes which will fit them for the new conditions under which they live. Experiments in this direction have in some instances met with unexpected success; and on the ground of this, societies have been formed in some of the principal European cities to accomplish the acclimatization of sub-tropical and some tropical plants to their latitude, and also of those belonging to colder regions.

ACCOLTI, *Benedetto*, an Italian lawyer, born at Arezzo in 1415, died in 1466. He became secretary of the Florentine republic in 1459. He is said to have had so fine a memory that, having heard an ambassador of Hungary deliver a Latin speech before the senate of Florence, he repeated it afterward, word for word. He wrote a work on the first crusade, from which Tasso drew the materials for his *Gerusalemme liberata*.

ACCOMACK, an E. county of Virginia, bordering on Maryland, and forming with Northamp-

ton county, from which it was set off in 1672, the peninsula on the E. side of Chesapeake bay; area, 480 sq. m.; pop. in 1870, 20,409, of whom 7,842 were colored. The surface is level and the soil light and moderately fertile. In 1870 the productions were 530,560 bushels of corn, 336,860 of oats, 97,730 of Irish and 212,507 of sweet potatoes, 7,991 lbs. of wool, and 40,284 of butter. Capital, Accomack Court House, or Drummond Town.

ACCORDION, a musical instrument, invented by Damian at Vienna in 1829, the sounds of which are produced by the action of the wind from bellows upon metallic reeds. It is played altogether by the hands, in which it is held.

ACERA, a country in western Africa, on the Gold Coast, over which England and Denmark exercise jurisdiction. The British division consists of Fort St. James, in lat. 5° 32' N., lon. 0° 12' W., and a very small territory, with a negro population of about 3,000. Crève-cœur, situated about one mile E. of Fort St. James, is an ancient Dutch settlement, which was destroyed by the English in 1782, partially rebuilt in 1839, and ceded to England in 1872. Acera is said to be one of the most salubrious localities on the coast.

ACCRINGTON, a town of Lancashire, England, 19 m. N. of Manchester, divided into Old and New, the latter the larger and of recent growth; pop. in 1861, 19,688; in 1851, 9,747. It is situated in a deep valley, is the centre of the Manchester cotton-printing business, and has besides several cotton factories, dyeing, bleaching, and chemical works, and coal mines. The streets are well paved and lighted.

ACCUBATION, a table posture, between sitting and lying, invented by the Greeks and adopted by the Romans and Jews. About the low dining table were placed two or three long couches, furnished with more or less

Accubation.

sumptuous draperies, on each of which lay usually three persons, on their left side, resting either their heads or elbows upon pillows, the feet of the first being behind the back of the second, and those of the second behind that of

the third. The middle place was considered the most honorable. Though this posture was at first considered immodest for Roman ladies, they soon indulged in it; but it was never permitted to children or persons of mean condition.

ACCUM, Friedrich, a German chemist, born in Bückeberg, March 29, 1769, died in Berlin, June 28, 1838. In 1793 he went to London, where he was appointed in 1801 professor of chemistry and mineralogy in the Surrey-institute. Being accused of purloining books and engravings from the library of the royal institution, he returned to Germany, and in 1822 was appointed professor in the school of industry and the academy of architecture in Berlin. He is known in connection with the introduction of gas lights in London. He wrote "A System of Chemistry" (2 vols., London, 1803), "A Practical Treatise on Gas Lights" (1815), and "On the Adulteration of Food."

ACELDAMA (Chaldaic, *'hahal dema*, field of blood), the name given to the potter's field which was purchased with the money for which Judas betrayed Christ. It was afterward used as a place of burial for strangers.

ACEPHALOCYST (Gr. *a* privative, *κεφαλη*, head, and *κυστις*, bladder; literally, a cyst without a head), a vesicular or hydatid growth, sometimes found in the substance of the liver, kidney, or other of the abdominal organs, in man and some of the lower animals. It is a globular bag or sac, having its walls composed of a condensed albuminous substance, of a laminated texture, and containing in its cavity a clear, colorless fluid, with albuminous or gelatinous ingredients. The main cyst produces smaller secondary cysts by a process of budding or outgrowth from its walls, and these secondary cysts are sometimes very numerous. They are developed between the layers of the principal cyst wall, and project sometimes internally and sometimes externally. Those species in which the young cysts project internally, and are thrown off into the central cavity, are called endogenous, and are found principally in the human subject; those in which they project externally are called exogenous, and are found in the ox and other ruminating animals. Acephalocysts are usually regarded as of a parasitic nature, and belonging to the class of cestoid worms, of which the ordinary tapeworm is the familiar representative. The embryo of these cestoid worms presents at one period a globular body armed with six calcareous hooks, which afterward becomes developed into a tapeworm head, enclosed in an inverted globular membrane. When one of these partially developed tapeworm heads is found by itself, surrounded by a cyst and imbedded in one of the internal organs, it is called a *cysticercus*. When the principal cyst enlarges and throws off a number of secondary cysts containing tapeworm heads, it is called an *echinococcus*. The acephalocyst is believed to be a growth having the same origin as the above, but in which for some reason the tapeworm heads either have not been developed at all, or have become disintegrated and disappeared. Hence its name, indicating the absence of the head, which, if present, would be decisive proof of its parasitic origin.

ACETATES, compounds of which acetic acid is one of the principal constituents. They are generally soluble in water and alcohol, and some of them are deliquescent; those that are least soluble are acetates of mercury, silver, molybdenum, and tungsten. There are three classes of salts, neutral, acid, and basic, all of them destroyed at a red heat or by sulphuric acid, which latter liberates acetic acid, easily recognized by its pungent odor. Heated with a mixture of sulphuric acid and alcohol, they give rise to acetic ether; with lime they furnish acetone, which has a peculiar characteristic odor; and distilled with caustic potash, they yield marsh gas. Their solutions yield a deep yellow color with ferric chloride (sesquichloride of iron), not given by free acetic acid. There are numerous acetates, some largely used in medicine and others in the arts. Among the former may be mentioned the following: potassic acetate, employed as a diuretic; ammoniac acetate, used as a diaphoretic; plumbic acetate (sugar of lead), used as an astringent. Of the acetates employed in the arts the most important are: acetates of alumina, manganese, iron, and zinc, largely used as mordants in calico printing; acetate of copper, verdigris, and a mixture of acetate and arsenite of copper called Schweinfurt green, employed in paints and for wall paper; acetate of lime, prepared as a crude material in the manufacture of acetic acid from the distillation of wood. Many modern chemists divide the acetates into two classes: 1. Metallic acetates, in which the basic hydrogen of the acetic acid is replaced by a metal or group; 2. Acetic ethers or organic acetates, in which the hydrogen is replaced by an alcoholic radical.

ACETIC ACID (Lat. *acetum*, vinegar, of which it constitutes about 6 per cent.) has been known in a dilute form from the remotest antiquity. It can be prepared in two conditions: acetic anhydride, or anhydrous acetic acid, and acetic acid. Anhydrous acetic acid, as obtained by Gerhardt, is a colorless, very mobile liquid, of high refracting power, having a very pungent smell and emitting a vapor which is extremely irritating to the eyes. It gradually absorbs moisture from the air, and becomes converted into the common acid. Acetic acid can be made in a great number of ways: by treating aldehyde, alcohol, and ethylic ethers with oxidizing agents; by fusing sugar, starch, oxalic acid, tartaric acid, or citric acid with potash; by submitting wood, sugar, and gums to dry distillation; by distilling gelatine, caseine, or fibrine with a mixture of sulphuric acid and manganese dioxide. It has been made synthetically by Wanklyn, by passing a current of carbonic acid into a solution of sodium methyl, and appears to exist ready formed in the juices of certain plants, such as the sap of the oak, and in some animal fluids. The product of the fermentation of wine and other spirituous liquids is vinegar, formed essentially of acetic acid diluted with water. (See VINE-

GAR.) The acetic acid employed in commerce is chiefly derived from the dry distillation of wood. The process, as described by the late William Allen Miller, is substantially as follows: Harder kinds of wood, particularly the oak, beech, birch, and ash, are subjected to destructive distillation in iron retorts by means of a heat gradually raised to low redness. The wood is usually placed in these retorts in loose iron cases, by which means the charge can be rapidly introduced without loss while the retort is still hot, and the charcoal can be withdrawn when the distillation is complete. The quantity of acid obtained varies from $1\frac{1}{2}$ to $3\frac{1}{2}$ per cent., and in the crude state is called pyro-ligneous acid, in allusion to the mode of its formation (Gr. *πυρ*, fire, and Lat. *lignum*, wood). During the operation a large quantity of tarry matter comes over, accompanied also by volatile and inflammable bodies, among which wood spirit, methyl acetate, and acetone predominate. These bodies are condensed in suitable receivers, while, in addition to carbonic anhydride, a considerable quantity of combustible gases, composed chiefly of hydrogen and carbonic oxide, is directed into the furnace, where they serve as fuel, and aid in heating the retorts. In about 24 hours, or as soon as the gases cease to escape, the loose iron cylinders containing the wood are withdrawn, and immediately closed with an air-tight cover, so as to allow the charcoal to cool excluded from the atmosphere. The crude acid liquid which has been collected in the condenser is decanted from the tar, and, when submitted to distillation, furnishes wood naphtha, which constitutes the more volatile portions; afterward the acetic acid is collected. The latter, however, is always accompanied by tarry matters. In order to get rid of these, the liquid is neutralized by the addition of the milk of lime or of sodic carbonate; a quantity of tar rises to the surface of the liquid on standing; this is skimmed off, and the solution of crude acid thus obtained is evaporated, and the dry residue, if the sodium salt be used, cautiously roasted at a temperature of about 500° F. (260° C.) to expel the tarry matters. It is afterward redissolved in water, decanted from the carbonaceous particles, which are allowed to subside, then recrystallized, and submitted to distillation with sulphuric or with hydrochloric acid, the sulphuric being preferable when sodic acetate is employed, while hydrochloric acid answers best when calcic acetate is used.—*Properties of Acetic Acid.* Normal acetic acid, $C_2H_4O_2$, is liquid at temperatures above 62·6° F. (17° C.); below this point it crystallizes in radiating tufts of plates, and is called glacial acetic acid. The concentrated acid has a sharp aromatic taste and a peculiar pungent odor; it blisters the skin if applied to it for a sufficient length of time. It boils at 242° F. (117° C.), and may be distilled unchanged. Its maximum density is 1·073, corresponding to a mixture of 77·2 per cent. acid

and 22·8 per cent. water. The vapor of acetic acid is inflammable, burning with a blue flame and producing by its combustion water and carbonic acid.

ACETYLENE, a transparent colorless gas, of a peculiar disagreeable odor, perceptible when coal gas is imperfectly burned in the air. It burns with a bright smoky flame. Berthelot formed it by transmitting olefiant gas or marsh gas through red-hot tubes. When copper service pipes are used for distributing coal gas, a dark-red copper compound is sometimes deposited which detonates powerfully on the application of heat or on receiving a sudden blow. Some serious cases of explosions in New York, where the pipes were undergoing repairs, were traced by Dr. John Torrey to this cause. When mixed with chlorine, acetylene explodes spontaneously; it has not yet been liquefied by cold or pressure.

ACHÆAN LEAGUE. The inhabitants of Achaia were a very inconsiderable member of the Hellenic family until about 251 B. C. They formed 12 separate self-governing communities, united together only by the religious bond of a common temple, common festivals, and common ancestry. In the repulse of the Persian invaders, in the Peloponnesian war, and in the resistance to Macedonian conquest, they took little part; and it was not until Athens, Thebes, and Lacedæmon had been subdued or humbled by Macedonian supremacy, that the insignificant Achæans became illustrious. When the Macedonian monarchy was reeling beneath the invasion of the Gauls, four Achæan towns formed a league for mutual protection in 281. Soon afterward Ægium ejected its garrison, and some others forced their tyrants, who governed in the Macedonian interest, to lay down their authority. In 251 Aratus, the Sicyonian, brought round his native town to the Achæan league, and got himself elected head of the confederacy. Corinth was freed from its garrison in 243 by the aid of the league, and was admitted a member. Megara, Epidaurus, Træzen, and the Arcadian cities joined soon after. In 208 Philipæmen, of Megalopolis, succeeded Aratus as general of the league. At this time, and especially after the total defeat of the Macedonian monarch at Cynoscephalæ, it was the only powerful state left in Greece, and the only possible bulwark against Roman power. When Sparta joined the league in 191 it included almost all the cities of the Peloponnesus, together with Athens, and several cities of northern Greece. For 50 years the Achæan confederation maintained the cause of Hellenic independence, and delayed the day of submission to Rome. (See GREECE.) At last the Roman senate succeeded in getting grounds of quarrel with the league, and sent Mummius over to complete the subjugation of Hellas. This was done in 146 by the defeat of Diaeus, the general of the confederates, before the walls of Corinth. All Greece was then made into a Roman province,

under the name of Achaia.—The Achæan league is the best example of the federative system bequeathed to the world by the Greeks. Each state or city, whether large or small, had but one vote, and retained its power of internal legislation, as well as its separate coins, weights, and measures, though the federal government had also its coins, weights, and measures, which were uniform. The right of intermarriage without loss of the children's citizenship, and the right of holding property and of importing and exporting on favorable terms, existed between the several cities of the federation, until taken away by the Romans, by way of punishment for resistance to their policy. The general assembly was held twice a year, but extraordinary assemblies were sometimes called. At the spring meeting the strategus or commander-in-chief, the hipparchus or master of the horse, and ten other functionaries called demiurgi, were elected. Although every citizen who could afford it might attend these assemblies, all the citizens of any one city could only throw one vote, a fact which made the larger cities, such as Corinth, discontented. Such a confederation in the age of Philip would probably have prevented the Macedonian conquest.

ACHÆANS, in ancient history, the name of one of the main divisions of the Hellenic race. Originally they dwelt in Thessaly, whence they migrated to the Peloponnesus, of which they were the ruling nation in the heroic period. Their name is therefore mentioned in the *Iliad* as a generic term for the Greeks. The well-greaved Achæans, the long-haired Achæans, are terms employed to designate the whole Hellenic host before Troy. Their mythological ancestor was Achæus, son of Xuthus, and grandson of Iellen.

ACHÆMENES. **I.** The ancestor and founder of the Achæmenidæ, the noblest family of the Pasargade, and from the time of Cyrus (third in descent from him, according to Herodotus) the royal family of Persia. In Latin poetry, *Achæmenius* is often used as a synonyme for *Persicus*, Persian. **II.** Son of Darius I., and brother of Xerxes, was made by the latter satrap of Egypt in 484 B. C., and accompanied him in his expedition against Greece in 480, when he commanded the Egyptian fleet. He fell in Egypt in 460, in an unsuccessful attempt to quell the revolt of Inarus, a Libyan chief.

ACHAIA, one of the ancient divisions of the Peloponnesus, extending along the coast of the gulf of Corinth; greatest length from E. to W. about 65 m.; breadth, 12 to 20 m. Patras, formerly Patræ, is the only Achæan town that has preserved any importance. The country was originally called *Ægialea*, that is, the coast-land, and inhabited by Ionians, who were dispossessed by the Achæans on the conquest of the Peloponnesus by the Dorians. After the Roman conquest of Greece and Macedonia, the province of Achaia included all Peloponnesus, with N. Greece S. of Thessaly.—In the present

kingdom of Greece it forms a nomarchy or province with Elis; area, 3,090 sq. m.; pop. in 1870, 149,561. Capital, Patras. (See *ACHÆAN LEAGUE*, and *ACHÆANS*.)

ACHARD, **Frauz Karl**, a Prussian natural philosopher and chemist, born in Berlin, April 28, 1753, died April 20, 1821. He devoted himself to the development of the beet sugar manufacture, repeating and improving upon the experiments of Marggraf. The results of his investigations were published in 1799 and 1800, but found neither encouragement nor imitation, upon which account the king of Prussia presented him with a farm in Silesia where he could continue his studies. In connection with Neubeck, he spent six years of laborious endeavor before he discovered the true method of making the sugar.

ACHARD, **Louis Amédée Eugène**, a French novelist, born at Marseilles in April, 1814. The first part of his life was employed in commerce and provincial administration, and he afterward became a journalist in Paris. In 1846 he accompanied the duke of Montpensier to Spain as a reporter. In 1847 he published *Belle-Rose*, a successful novel (5 vols. 8vo.), since which he has produced many others, besides a number of plays.

ACHATES. **I.** The companion of Æneas in his flight from Troy, and in his subsequent wanderings, according to the account given by Virgil. He is always termed *fidus Achates* (the faithful Achates), whence the phrase has passed into a proverb, applied to any faithful confidant in a subordinate position. **II.** In ancient geography, a river in the south of Sicily, between Camarina and Gela, now called Dirillo. According to Pliny, it was the place where the first agate was found; hence the derivation of the word agate.

ACHEEN, an independent sovereignty, comprising the N. W. portion of Sumatra; area, 25,500 sq. m. As early as 1509 the Portuguese visited this country, and in 1602 the English, in order to obtain a continuous supply of pepper, entered into a commercial treaty with the king. The East India company in 1659 established a factory at the capital; but it was eventually removed to Bencoolen, on the S. coast of Sumatra. Sir Stamford Raffles in 1819 secured to the East India company and the British government, by treaty, the right of freely trading to all the ports of Acheen. The government of Acheen is an hereditary monarchy, the power of the king or sultan being limited only by the power of his greater vassals. The kingdom is divided into 190 small districts. This part of Sumatra is comparatively healthy, but the interior is almost entirely unknown. The people are taller, stouter, and darker than the other Sumatrans. They are strict Mohammedans, and write in Malay characters. They manufacture a few silk goods, and a good deal of thick cotton cloth and striped and checkered stuffs.—**Acheen**, the capital, stands about a league

from the sea, on a river that empties at Acheen head, the extreme N. W. point of Sumatra. The roadstead is good, being safely sheltered by several small islands. A bar at the mouth of the river prevents all but vessels of three or four feet draught from entering it. Most of the houses are built of bamboos and rough timber raised on piles, to escape inundation. The city contains many fine buildings, among which are numerous mosques and other public edifices, and the fortified palace of the king. It had formerly about 36,000 inhabitants, but is now on the decline.

ACHELOUS (now *Aspropotamo*), a river of Greece, which rises in Mount Pindus, flows S., separates Ætolia from Acarnania, and falls into the Ionian sea. Homer calls it the "king of rivers." It is the largest stream in Greece, its length being 130 miles.

ACHENBACH. **I.** Andreas, a German landscape painter, born in Cassel, Sept. 29, 1815. He studied at Düsseldorf, under Schirmer and Schadow, and at the age of 18 produced landscapes of merit. He afterward travelled over many parts of Europe in search of subjects, and took particular delight in reproducing the scenery of Norway, the Alps, and the Tyrol. His Italian landscapes are also impressed with a fine feeling for the picturesque. As a painter of the grand and savage aspects of nature, he holds a high rank. His works are widely scattered over Europe, and a number are owned in the United States. **II.** Oswald, brother of the preceding, also a painter of the Düsseldorf school, born in that city, Feb. 2, 1827. Since 1863 he has been professor of landscape painting at the Düsseldorf academy. His best pictures are of Italian scenery. His "Funeral of Palestrina" was rewarded with a medal at the Paris exposition of 1861.

ACHERON, in antiquity, the name of several rivers, all believed to be connected with the lower world. **I.** A river in Epirus, which flowed through Acherusia lake into the Ionian sea. **II.** A river in Elis, an affluent of the Alpheus. **III.** A river in Bruttium, S. Italy. **IV.** The river of the lower world, around which the shades were believed to hover. The name was also used for the lower world in general.

ACHERUSIA, in antiquity, the name of several lakes believed to be connected with the lower world. The principal ones were those in Epirus and Campania, the latter between Cumæ and Cape Misenum. Acherusia was also the name of a chasm in Bithynia, into which Hercules descended to bring up Cerberus.

ACHÉRY, Dom Jean Luc d', a French savant, born in 1609, died April 24, 1685. He was a Benedictine monk, librarian of the abbey of St. Germain des Prés at Paris, and devoted his life chiefly to collecting and editing documents relating to mediæval ecclesiastical history. His principal work was *Veterum aliquot Scriptorum qui in Gallie Bibliothecis maxime Benedictinorum latuerant Spicilegium* (13 vols. 4to, 1655-77; afterward reëdited by Barre, 3 vols.

fol., 1723). He also assisted in the *Acta Sanctorum Ordinis S. Benedicti* (9 vols. fol.).

ACHILLES, properly **Achilleus**, the hero of the Iliad, was the son of Peleus, king of the Myrmidons in Phthiotis in Thessaly, grandson of Æacus, and thus third in descent from Zeus. His mother was the sea goddess Thetis, daughter of Nereus; hence he is often called Pelides, Peleïades, and Æacides. The story of his early life is told in different ways. One account is, that his mother, foreseeing his early death, endeavored to save him by dipping him in the river Styx, whose waters had the property of rendering the human frame invulnerable. The heel by which she held the babe was not wetted, and remained the sole vulnerable point of the hero. He was educated by Phœnix, who taught him war and eloquence, and by Chiron the centaur, who taught him the healing art. To keep him out of danger, Thetis disguised him as a maiden, and sent him to the court of Lycomedes, king of Seyros. Here his real character was soon discovered by the birth of a son to him, named Neoptolemus or Pyrrhus, by Deïdamia, the daughter of Lycomedes. The prophecy was that Troy would never be taken in the absence of Achilles, and the crafty Ulysses was sent to discover him. Disguised as a peddler, he offered the Seyrian maidens female trinkets and weapons of war; all of them chose ornaments, but the disguised hero clutched the sword and shield. He went to Troy, accompanied by his tutor Phœnix and his friend Patroclus, and at the head of his Myrmidons, in 50 ships of war. Previous to his dispute with Agamemnon he ravaged the country round Troy, and took and destroyed 12 towns on the coast and 11 in the interior. Briseïs was his favorite female slave and concubine, whom he had captured at the sack of Lyrnessus. The commander-in-chief, Agamemnon, claimed her as indemnity for his slave Chryseïs. Achilles obeys on the entreaty of Minerva, but retires to his tent in wrath and resentment, refusing to take further part in the campaign. The Greeks suffer a myriad of woes in his absence, but no calamity will change his decision. At last his bosom friend Patroclus gains his permission to put on the armor of Achilles, and show himself to the Trojans. Believing that Achilles has come, they flee in panic. Patroclus presses on, and is slain by Hector. Then Achilles, in the desire to avenge his friend, reconciles himself with Agamemnon, receives Briseïs again, gets a new suit of armor from Vulcan, including the far-famed shield, which is brought to him by his mother, and rushes into the fight. He slaughters a great number of Trojans, contends with the river god Xanthus, whose course he has heaped with corpses and defiled with blood, and drives all the Trojans within the walls of their city. Hector alone dares to withstand his course. Achilles chases him three times around the walls of Troy, slays him, and, tying the body to his chariot, drags it into the camp of the

Greeks. He institutes games in honor of his friend, and slays 12 captive Trojan youths on the funeral pyre, to satisfy the manes of Patroclus. Priam, led by Mercury, penetrates to his tent, and prevails upon him to allow the body of Hector to be ransomed. We hear no more of Achilles in the Iliad. The accounts of his death are various. One represents him as falling by the arrow of Paris, directed by Apollo at the vulnerable heel, when he was in the temple of that god, about to espouse at the altar Polyxena, the daughter of Priam. His remains were collected in a golden urn, and a cenotaph was erected to him on the promontory of Sigeum. This monument was always an object of veneration to the Greeks; Alexander the Great performed a pilgrimage to it, and ran naked three times around it.

ACHILLES TATIUS. I. A Greek astronomer, supposed to have flourished in the 4th century of our era, and to be the author of a treatise on the sphere, a fragment of which is extant. II. A native of Alexandria, who wrote a Greek romance entitled "The Story of Leucippe and Clitophon," which has come down to us. He probably wrote near the close of the 5th century. By some biographers these two writers are considered identical.

ACHMET. See AHMED.

ACHMIM. See EKIMIN.

ACHROMATIC LENS (Gr. *a*, without, and *χρῶμα*, color). When light is refracted by any transparent medium, dispersion always takes place; that is, the rays of different color contained in white light are not equally refracted or deviated from their path. It would seem that the amount of this dispersion must always be proportional to the amount of refraction, but experiments have shown that diverse refracting substances differ considerably in this respect. Their dispersing and refracting properties are determined by passing a ray of light through solid prisms of different material, or liquid prisms enclosed between glass plates. The refracting power is then measured by the amount of deviation of the ray, and the dispersive power by the length of the colored spectrum produced. So it has been found that if the relative amounts of refraction of water, crown glass, flint glass, and oil of cassia are expressed by the numbers 133, 152, 162, and 159, the amounts of dispersion or the lengths of their spectra are in ratio of 145, 203, 433, and 1,080. If the angle of a prism is increased, the refracting and dispersing power both increase in the same ratio; and it is evident that two prisms of different material may be made at such angles that they produce the same length of spectrum, or possess the same dispersion, but that then their refracting powers will not be the same. In figs. 1 and 2 two such prisms are represented, the first refracting more than the second, but giving equal lengths of spectra. If now two such prisms are joined in opposite directions, as represented in fig. 3, they will cause a neutralization of the equal spectra, but

not of the unequal refraction, and therefore they will produce a deviation or refraction of

Refraction and Dispersion by Prisms.

the rays without dispersion of the light; no colored spectrum will be produced, but only a pure white spot will be the result of such a combination, which is called an achromatic prism. This is the principle on which the lenses in all our modern telescopes, microscopes, photographic and other optical apparatus are constructed. A convex lens of crown glass brings the rays together to a number of differently colored foci, of which the red rays will be the furthest from the lens, fig. 4. (See ABERRATION, CHROMATIC.) A concave lens will throw the red rays nearer to the axis, fig. 5; but if this concave lens is made of flint glass (a material having a slightly greater refracting

Refraction and Dispersion by Lenses.

but a much greater dispersive power), and ground to such a curve as completely to neutralize the dispersion or coloring of the first lens, while it affects its refraction only so far as to lengthen its focal distance, the combina-

tion will bring the rays to a focus without separating the luminous rays into their colored constituents; see fig. 6. Such a lens is said to be corrected for chromatic aberration. Sometimes the concave correcting lens of flint glass does not quite accomplish the purpose, and then the combination is said to be under-corrected; but sometimes the opposite is the case, when the combination is said to be over-corrected. In this case the chromatic aberration will be the reverse of what it is with a single convex lens. As the different parts of the colored spectra produced by different media have not an exact proportionality toward one another, an absolute achromatism is impossible; but successful attempts have been made to cure it in some degree by the addition of a third lens of plate glass. Attempts to make achromatic lenses by enclosing fluids of different diffractive powers between glass lenses have all failed, by reason of the variability in such fluids; in the course of time portions of higher refractive power will accumulate at the lower sides, and by changes of temperature currents will be set up which disturb the images seen. As the manufacture of flint glass for large achromatic lenses is a very difficult and uncertain operation, and therefore very expensive, their size has been reduced by placing an over-corrected combination of half the size in the middle of the telescope; such an instrument is called a dialitic telescope. Recently the plan of the elder Herschel has been revived, namely, to use no large achromatic objective lenses at all, but reflectors, which of course can have no chromatic aberration, which is the result of refraction.

ACID, a compound of hydrogen, in which that element is united to an electro-negative radical. In common language the term is equivalent to the Latin word *acidus*, meaning anything sour. Oxygen was formerly considered to be the element upon which the existence of the acid character mainly depended, as its name (signifying generator of acids) implies; but later researches have brought to light a number of compounds containing hydrogen possessed of acid properties in which oxygen is not present. Hence hydrogen is now regarded as more truly the generator of acids than oxygen. The usual test for the presence of an acid is its property of changing blue vegetable colors to red. We are already acquainted with several hundred acids, most of them belonging to the organic kingdom, and new ones are constantly discovered by chemists. The juices of plants and the constituents of animal bodies furnish their peculiar acids; and with the changes these undergo new acids are generated by different modes of combination, which processes are now imitated by art so as to reproduce by synthesis a number of organic acids. Some acids, when uncombined, are gaseous, others fluid, and others solid. Their properties also are as various as the conditions in which they exist.

ACILIUS GLABRIO, *Manius*, a Roman general, who became consul in 191 B. C. He was of plebeian origin, but rose by regular gradation. He supported Cornelius Scipio; commanded as consul against Antiochus the Great of Syria, and defeated him at Thermopylæ; and subsequently carried on the war against the Ætolians with equal success. On his return he had a triumph. But this elevation and success of a plebeian gave offence to the patricians of Rome, who stirred up annoyances and accused him of keeping back the public spoils; but he was not condemned. He was the first to whom a statue of gold was erected in Italy. He wrote the annals of Rome in Greek, a narrative full of fables.

ACI REALE, a seaport town on the E. coast of Sicily, in the province of Catania, celebrated for its mineral waters; pop. in 1871, 35,787. It is situated on a hill of lava with a precipice over 650 feet high facing the sea, in the highly picturesque region between Mount Etna and Catania, 11 m. N. N. E. of the latter, at the mouth of the small river Aci; is well built, principally of lava, and has many churches, convents, and towers. Great quantities of diaper are made. Near the town are the famous cave of Polyphemus and the grotto of Galatea.

ACIS, in Ovid, son of Faunus and Symæthis, beloved by the nereid Galatea, and through jealousy crushed to death under a huge rock by Polyphemus. Galatea changed his blood into the river Acis, on which now stands the town of Aci Reale, where the scenes of the legend are still shown.

ACKERMANN. **I. Konrad Ernst**, a German comedian, regarded as one of the founders of the German stage, born in Schwerin in 1710, died in Hamburg, Nov. 13, 1771. In 1740 he made his début as an actor under the auspices of Schönnemann, and afterward organized a travelling company, with which he performed in many places. He is celebrated as the founder of the Hamburg theatre (1765), whose performances inspired Lessing's famous comments on dramatic art. **II. Sophie Charlotte**, wife of the preceding (1749), previously widow of the organist Schröder, born in Berlin in 1714, died Oct. 14, 1792. She was not only distinguished as an accomplished actress both in tragedy and comedy, and teacher of the histrionic art, but also as the mother by her first marriage of Friedrich Ludwig Schröder (see SCHRÖDER), and of two daughters by her second marriage, also very distinguished: **DOROTHEA**, who retired from the stage in 1778 on marrying Prof. Unzer, and **CHARLOTTE**, whose death in 1775, in her 18th year, was generally deplored at Hamburg.

ACLAND. **I. John Dyke**, a British major, son of a baronet, commander of the grenadiers in the battle of Stillwater in the American revolution, Oct. 7, 1777, died in 1778. When overpowered by numbers the British retreated to their camp, which was furiously stormed by

Arnold. Major Acland was shot through the legs and taken prisoner. When Gen. Fraser was brought mortally wounded to the quarters of the baroness de Riedesel, a report reached Lady Harriet Acland (daughter of the earl of Hechester), in a tent near by, that her husband was also mortally wounded. She determined to seek him in the American camp, although she was at the time much debilitated by want of food and rest, and by anguish of mind. She was received with kindness; her attentions restored her husband to health, and the bearing of the Americans toward both made a profound impression on the mind of Major Acland. After his return to England the next year, he was provoked to give the lie direct at a dinner party to Lieut. Lloyd for some foul aspersions on the American name. A duel ensued, and Major Acland was shot through the head, a circumstance which caused his devoted wife the loss of her senses for two years. She afterward married the Rev. Mr. Brudenell, a chaplain in the British army, who had accompanied her in her perilous pursuit of her husband, and died in 1815. She wrote a narrative of the campaigns of 1776-7.

H. Henry Wentworth, M.D., F.R.S., grand-nephew of the preceding, born in 1815, physician to the Radcliffe infirmary, and Lee's reader in anatomy at Oxford, is distinguished as a promoter of sanitary reform. He accompanied the prince of Wales to the United States in 1860 as his medical attendant.

ACLINIC LINE (Gr. *α*, without, and *κλίσις*, to incline), an imaginary line on the earth's surface between the tropics, where the compass needle has no inclination; that is, where the dipping needle is horizontal. This line is also called

the magnetic equator, being about 90° distant from the magnetic poles; it is variable and runs quite irregularly. At present it intersects the geographical equator near the W. coast of Africa, and some 160° E. of that point in the Pacific ocean. In the western hemisphere it is S. and in the eastern N. of the equator.

ACEMETE (Gr. *ακοιμητος*, sleepless), an order of Greek monks who chanted the divine service day and night, without ceasing. This they accomplished by dividing themselves into three reliefs, succeeding one another alternately. Their centre was the cloister of Irenarion, near Constantinople. They flourished in the 5th century; in the succeeding century they were put under the ban of the

church, on account of their leanings toward the Nestorian Christians and their doctrines.

ACOLYTE (Gr. *ακολουθος*, attending), a clergyman in the Roman Catholic church, and in the churches of the East, next in rank to the sub-deacon, whose principal office is to light the candles on the altar, and attend on the priest or other sacred ministers during mass and vespers. The youths who serve at the altar are also called acolytes, though not ordained.

ACOMA, a village of New Mexico, in lat. 35° 24' N., lon. 106° 10' W., supposed by the abbé Domenech to be the Acuco of the ancient Spanish historians, and the oldest Indian town in the territory. It is built upon the horizontal summit of an isolated and almost perpendicular rock 394 feet in height. The greater part of the ascent to it is made by means of a road cut like a spiral staircase in the rock. The village consists of large blocks of houses, 60 or 70 in each block. It is said the Spaniards took the town from the Indians in 1599.

ACONCAGUA. **I.** A central province of Chili; area, about 6,000 sq. m.; pop. in 1868, 130,672. The entire eastern portion is occupied by rugged spurs of the Andes and very fertile valleys, watered by several rivers flowing through the province to the Pacific. This region abounds in copper, silver, and gold mines; the last were at one time very famous. In 1862 there were in working order 8 gold, 9 silver, and 228 copper mines. The western part is irrigated by innumerable artificial water courses, supplied from the rivers, by means of which large crops are produced of excellent wheat and other cereals, as well as of hemp of a very superior quality. Such irrigation is rendered indispensable by the extraordinary scarcity of rain. The province is divided into the five departments of Andes, Ligua, Petorca, Patacuco, and San Felipe. Capital, San Felipe de Aconcagua, situated at the foot of the Andes, in a fertile valley 2,000 feet above the Pacific, 55 m. N. E. of Valparaiso; pop. about 7,000. **II.** A peak of the Andes in the preceding province, N. E. of San Felipe, in lat. 32° 39' S., lon. 70° W., believed to be the highest in this hemisphere. According to the measurement of M. Pissis, to the results of whose labors more credit is given than to those of any other scientific investigator of the Andes, Aconcagua reaches a height of 6,834 metres, or 22,422 feet, above the level of the ocean, being 997 feet higher than Chimborazo and 1,138 feet higher than Sorata, which were formerly considered the most elevated peaks of the Andean chain. Aconcagua has been described as the cone of an extinguished volcano, and the error probably arises from a widely published statement of Darwin, who asserts that when in the Beagle expedition in 1835 it was reported to him that the volcano of Aconcagua was in eruption. Neither its shape nor its external features would indicate an extinguished vol-

cano; it is a colossal, angular, and serrated mass, without any lava or other vestiges of volcanic action, and can only be seen in all its grandeur from the east, because the mountains which surround it on the west impede the view. From Valparaiso a view of the peak only, rising far above the summits of even that gigantic chain of mountains, is obtained.

ACONITE (Gr. *ακονίτιον*, probably from *ακονη*, a stone, because it grows in stony places), a genus of plants of the order *ranunculaceæ*, one of the distinguishing marks of which, the hooded form of the upper sepal, gives the name monkhood to a cultivated species. A plant of this name was known to the ancients, and may have been one of the species now belonging to the genus. The species at present in use as a medicament is the *aconitum napellus*, cultivated in our gardens under the name of monkhood; but several other species possess similar properties in at least an equal degree. Among these are *A. lycotonum* and *A. ferox*. Probably the latter, from which the *bish* root of Nepaul in India is obtained, possesses the most deadly qualities. This was used by the natives to poison their wells on the advance of the British

Aconitum napellus (Monkhood).

army into their territories. Some of the cultivated varieties of *A. napellus*, having leaves of a lighter shade of green, with blue and white flowers, have less acridity than the darker variety, and would probably, if used, be found to possess less medicinal power.—From the roots and leaves of the official species are prepared extracts and tinctures. Those from the root are the most powerful, and are largely used in medicine. The physiological action of this drug depends chiefly, and probably entirely, upon the alkaloid aconitia, though two other alkaloids, aconella and napellina, besides aconitic acid, are among its constituents. Aconitia is a white substance, not volatile at ordinary temperatures, slightly soluble in water, and readily so in alcohol ether, and chloroform. It is probably

not crystallizable, and the crystallized specimens exhibited as such consist partly of aconella, which is crystallizable and inert in doses in which aconitia would be fatally poisonous. This statement derives support from the fact that the French and German aconitia, which is partially crystallizable, is much weaker than the English. This alkaloid is one of the most powerful known poisons. One fiftieth of a grain has repeatedly proved fatal to dogs, and nearly so to man. Its effects, which may be considered equivalent to those of a corresponding dose of aconite or its tincture, are a burning and swelled feeling of lips, tongue, and pharynx, nausea and sometimes vomiting, headache, shooting pains of the face, difficult respiration, general prostration, and, after a slight preliminary rise, a marked diminution of the frequency and force of the heart's pulsations. As the fatal dose is approached the pulse again becomes rapid and feeble. The mind is clear, and there is but little somnolence; the pupil is dilated, but less so than by atropia. Fatal poisoning has taken place, not only from the use of the medicinal preparations of the drug, but from its being mistaken for horseradish or other edible plants, from which with care it can be readily distinguished.—The therapeutic action of aconite is obtained by doses much smaller than those which give rise to the effects just described. A slight tingling of the lips and tongue may be regarded as a sign that the dose is not to be increased. Since its action, after a primary slight stimulant effect, is essentially to diminish the activity of the nervous system, and secondarily that of the heart, it is used in medicine for two objects: first, to diminish pain, as in neuralgia; and secondly, to diminish the activity of the heart in inflammatory diseases. According to some observers, aconite possesses a greater power in the reduction of certain kinds of inflammatory fever than can be accounted for by the effects upon the heart described above; but it is to be remembered that some of the diseases in which aconite is supposed to display peculiar power, tonsillitis for instance, have naturally a very limited duration. It is admitted by most observers that the curative effect of aconite is displayed chiefly in the early stages of inflammations. The list of diseases in which aconite has been used is very large, embracing those in which inflammatory or neuralgic symptoms are prominent. In poisoning by this drug, after evacuation of the stomach, stimulant remedies, such as alcohol, wine, and brandy, and dry heat to the surface, should be used.

ACONITE, Winter (*eranthis hycmalis*), a small tuberous and herbaceous plant, growing without stem, and bearing in early spring bright yellow flowers of cup form. Its leaves are smooth, pale green, many-cut, and peltate; and its scape, only a few inches high, is single-flowered.

ACONITIA. See **ACONITE.**

ACOSTA. I. José de, a Spanish writer, born about 1539, died Feb. 15, 1600. He entered the society of Jesuits at 14, and on completing his course of study was appointed professor of theology at Ocaña. In 1571 he was sent as a missionary to South America, of which, after his return to Spain, he published a history (*Historia natural y moral de las Indias*, Madrid, 1590). This work has been translated into several languages. He also wrote *De Natura Novi Orbis*, and some other works, chiefly of a polemical character. II. **Uriel**, a Jewish writer, born in Oporto, Portugal, about 1590, died by his own hand in Holland in April, 1647, or, according to some accounts, in 1640. He belonged to a family converted to Christianity at the time of the expulsion of the Jews from Portugal, and was educated by Catholic teachers, but soon conceived doubts concerning the Christian doctrines. He finally fled, with his mother and a brother, to Amsterdam, embraced the faith of his ancestors, and exchanged his original name Gabriel for Uriel. He failed, however, to recognize in the rabbinical Judaism of his time the ideal of his independent speculations, and became involved in a passionate controversy with the religious heads of the Jewish congregation of Amsterdam, in the course of which, having suffered excommunication, he published in Portuguese a "Criticism of the Pharisaic Traditions, compared with the Written Law," in which he repudiated the doctrine of the immortality of the soul. He was now arraigned before the magistrates and heavily fined. After many years of exclusion from the synagogue he signed a recantation of his views, but subsequently again provoked the ire of the orthodox, among whom were his own relatives, was a second time excommunicated, and finally submitted to an ignominious public chastisement. Maddened by persecution, he put an end to his life by a pistol shot, leaving an autobiography, which was published in Latin and German in 1687. III. **Joaquín**, a South American historian, colonel of engineers in the Colombian service, died about 1862. In 1834 he explored the valleys of the Socorro and Magdalena rivers with the botanist Céspedes, and in 1841 made researches relative to the Chibchas and other aboriginal tribes. He continued these investigations in the archives of Spain and France, and in 1843 published in Paris *Compendio historico del descubrimiento y colonizacion de la Nueva Granada, en el siglo decimo sexto*. In 1849, in conjunction with M. A. Laserre, he published a new and enlarged edition of the celebrated *Semenario de la Nueva Granada*, with a biographical notice of the author, the learned Caldas, who was shot in 1816. A series of archeological essays were furnished by Acosta, for publication, to the Paris geographical society, 1854 *et seq.*

ACOUSTICS (Gr. *akouein*, to hear), that branch of physical science which explains the phenomena and laws of sound. For the production of these phenomena three conditions are required: 1, a sonorous body; 2, a medium to propagate, and 3, an organism to perceive the sound. From these conditions the science of acoustics is naturally divided into three branches, of which the last belongs entirely to the field of physiology, or rather biology, while in the first two the most intricate and at the same time most successful application of mathematics to mechanical science is to be found. A superficial examination into the cause of sound shows that it originates in vibrations of the sounding body, and is thus a result of its elasticity. The air, being very elastic, is ordinarily the medium by which sound is transmitted to our ears; but most other bodies, solid as well as liquid, transmit sound as well and even better than air, while in a vacuum transmission ceases, as is proved by the well-known experiment of exhausting by means of an air pump the air from around a continuously ringing bell. The phases of the sonorous vibrations are appropriately called undulations or waves; they are communicated to the body transmitting the sound by one or more impulses from the sonorous body, and are transmitted by alternate compressions and expansions of the parts. The velocity of this transmission for air at the freezing point of Fahrenheit is 1,090 feet per second, and about one foot more for every degree above. Very violent sounds, however, travel faster, as proved by Boyden in Boston and Earnshaw in Sheffield, England; the cause of this is the heat developed by strong compression of the air by a powerful wave of sound. Heavy gases transmit sound slower and light gases faster than air: carbonic acid 858 feet, hydrogen 4,164 feet per second. Water transmits sound with about the same velocity as the latter, while alcohol, ether, and turpentine transmit it slower (3,800 feet), and saline solutions in water faster (from 5,000 to 6,500 feet per second). Through metals the transmission is in round numbers as follows: lead, 4,000 feet per second; copper, 11,000; iron and steel, 16,000. If a wave is violent enough to produce a shock against the drum of the ear, a sound is always heard even if there be but a single wave; such is the case with a clap of thunder, the explosion of a gun, or the crack of a whip. But if the waves are weak, such as those produced by the vibration of a string, there must be a succession of them at a certain rate of rapidity, in order to make the sound audible. If these waves succeed one another at regular intervals and thus have equal lengths, we have a musical tone; if irregular, they produce merely a noise.—The lowest tone used in music is produced by an organ pipe nearly 32 feet long, in which the tone is produced on the same principle as in the flute, by blowing a current of air against a sharp edge;

the friction causing a vibration of the air column in the pipe, on the same principle as the friction of a violin bow causes the vibration of a string. The length of the wave produced in an organ pipe is equal to the length of the pipe; and as sound travels through air with a velocity of about 1,090 feet per second, it must pass through a pipe 32 feet long in nearly the 32d part of a second, and thus produce 32 waves per second. If the pipe is 16 feet long, we must have 64 waves per second; for an 8-foot pipe, 128 waves; 4 feet, 256; 2 feet, 512; 1 foot, 1,024; 6 inches, 2,048; 3 inches, 4,096; and $1\frac{1}{2}$ inch, 8,192 waves. These are the correct velocities of vibrations of the tones represented by the note called C, Ut, or Do, from octave to octave, according to the so-called theoretical pitch. In Handel's time the lower C corresponded to 31 vibrations per second, and the Italian opera in London had it in 1859 at 34 vibrations; while the pitch recently established by the French conservatory of music and by a congress of musicians in London agreed to nearly 33 vibrations, corresponding to the Stuttgart pitch. Only the eight octaves mentioned above are used in music. The capacity of the ear, however, extends an octave below the lowest and more than two above the highest of these figures, being between 16 and 38,000 vibrations per second; but there is a difference in this regard between individuals, some persons being perfectly deaf for very low or very high tones distinctly heard by others. The seven different tones of the so-called diatonic scale are interpolated between the octaves given above, and expressed by the customary notes and staff of five lines with clef, or by the letters C, D, E, F, G, A, B, C. They correspond for the lower octave with the velocity of vibrations 32, 36, 40, $42\frac{2}{3}$, 48, 54, 60, and 64 vibrations per second respectively; by multiplying either of these numbers by 2, 4, 8, 16, &c., we obtain the velocities of any other octave. It is seen that some of these numbers bear simple ratios to one another, as C:C = 1:2, C:G = 2:3, C:F = 3:4, C:E = 4:5, E:G = 5:6; these tones harmonize, the others are discordant. The further comparison of the numbers shows that the differences between the 3d and 4th and between the 7th and 8th of the scale are less than those preceding or following. This has given reason for the interpolation of five other tones between those of which the differences are greater, so as approximately to equalize these differences; in this way 12 tones in each octave have been obtained, forming a scale called chromatic. These interpolated tones are inappropriately called semitones, and designated with the same sign as the next note, but preceded by a \sharp (sharp) or \flat (flat). This scale is represented in the velocity of vibrations and in name as follows:

82	84	86	88	42 $\frac{2}{3}$	45	48	51	54	57	60	64
C	C \sharp	D	D \sharp	E	F	F \sharp	G	G \sharp	A	A \sharp	B
C	D	E	F	G	A	B	C				

The keyed instruments give a material representation of this scale. The relation of progression between its tones, when tuned according to the proportions given here, is so irregular, that when transposing the diatonic scale, that is, when commencing it at another tone than C, very impure harmonies are obtained. This is corrected, or rather compromised, by making the mutual proportions of the 12 numbers representing the chromatic scale such as to obtain a regular geometrical series; this is the so-called equal temperament. In order to accomplish this with strict mathematical accuracy, we have only to interpolate 11 terms of such a series between the numbers 1 and 2, which express the relations between a tone and its octave; this is mathematically expressed by the series

$$2^0, 2^{1/12}, 2^{2/12}, 2^{3/12}, 2^{4/12}, \&c., \text{ to } 2^{11/12};$$

or by logarithms: $\log. 1\frac{1}{12}, \log. 1\frac{2}{12}, \log. 1\frac{3}{12}, \&c.,$ to $\log. 2$, which by calculation gives the series 1.000, 1.0594, 1.1225, 1.1892, 1.2599, 1.3348, 1.4142, 1.4983, 1.5874, 1.6818, 1.7818, 1.8877, 2.000. Multiplying each of these numbers by 32, we obtain the velocity of vibration for the lower octave, for the absolute equal temperament:

32-000	33-8903	35-9200	38-0544	40-8163	42-7186
C	C \sharp	D	D \sharp	E	F
45-2544	47-9456	50-7963	53-8176	57-0176	60-4064
F \sharp	G	G \sharp	A	A \sharp	B
					C

It is seen, by comparison with the numbers mentioned before, that this series gives C \sharp , D, G, and G \sharp too low, while the other eighth tones are too high. However, this is only the case when considering the interpolated semitones as sharps; but as we must use C \sharp for D \flat , D \sharp for E \flat , &c., and the calculation for the tones corresponding with these flats gives us different figures, between which and the former the equal temperament is a compromise, the advantages are acknowledged to be with the latter, and it is now therefore universally adopted. (See MUSIC.) A column of air in a pipe will not necessarily vibrate in such a way that each wave will be equal to the length of the pipe. By modifying the manner of admitting the air, either by increased pressure or changing the aperture, the waves may be made one half, one third, one fourth, one fifth, &c., of the length of the pipe. In this way the so-called harmonics and the tones of the French horn are produced. They are called over-tones, if the fundamental vibration producing the lowest tone is still heard at the same time. In order to produce all kinds of shorter waves by means of the same pipe, holes may be made in its sides, closed by the fingers or by proper valves. The opening of these holes is nearly equivalent to a shortening of the pipe. Thus the different tones of the flute, clarinet, haut-bois, bassoon, and several other wind instru-

ments, are produced. In the trombone, the length of the tube is increased and diminished by a sliding arrangement; while in the cornet à piston and similar brass instruments, the same elongation and shortening is produced by piston valves admitting or shutting off the air from side channels of greater or lesser length. In stringed instruments the same results are accomplished by different length of strings. As in the organ every pipe produces only a single tone, so in the pianoforte every string is intended for one tone; while in the harp, by a slight shortening, the pitch of each string may be raised a so-called semitone. In all the other stringed instruments, as the violin, violoncello, and guitar, the different tones are produced by the use of very few strings only, which, however, by proper manipulation with the fingers, may be shortened so as to produce tones of which the vibrations become faster in proportion as the sounding portion of the string is shortened. In regard to the law governing their vibration, it is the same for strings as for pipes. Other circumstances being equal, their velocity is inversely proportional to the length of the pipe or string. The tone of strings also changes by change of tension, and the velocity of their vibration is in the ratio of the square root of the weights which produce this tension. Further, the tone depends upon the thickness of the string, its rigidity, weight, and nature of material. When a string is subdivided into a number of equal parts, these parts will vibrate simultaneously, leaving the points of division at rest, and produce the harmonic tones, after the same law as in the case of a column of air in the French horn. The subjoined five figures give the manner of vibration of a string as a whole, half, third, fourth, and fifth parts, producing different

On the violin these subdivisions may be effected by slightly touching the string on one of the points dividing it into equal parts, and the harmonic upper tones thus produced are called the flageolet tones. In the Æolian harp, in which the strings are put into vibration by the friction of a current of air, these divisions are incidentally and continually changing, and thus a variety of harmonic tones is produced. The division points, where the string happens to be at rest, are called nodal points. An elastic plate of glass, brass, steel, or other suitable material, may also be made to vibrate and emit tones; and when fixed at one point and excited at one of its edges by a violin bow, it may be made to produce a considerable variety of tones, by the fact that it may be subdivided into various systems of nodal lines; the spaces between these lines are the sounding portions, and the vibrations are more rapid or the tones sharper in proportion as these spaces are smaller. These nodal lines may be made visible by scattering dry sand over the plate, and when it is put into vibration with the violin bow, the grains of the sand which are not on the nodal lines will be thrown aside, and not come to rest until they are accumulated upon the nodal lines. Thus many kinds of regular and almost geometrical figures may be formed, which are called, after the inventor of this method, Chladni's nodal sound figures. With different forms of plates, many hundreds of such figures have been obtained. Our figures illustrate only a few of the most remarkable. The first and most simple is produced by the lowest

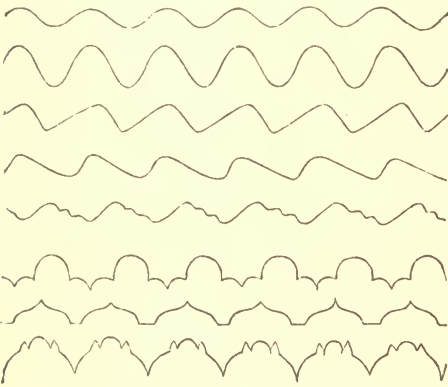

Chladni's Nodal Sound Figures.

tone which can be obtained from the disk; the others belong to higher and higher tones, while the last and most complicated is produced by the highest tone; in this case the smallest parts of the glass disk vibrate for themselves, and produce then the most rapid vibrations. It is thus seen that every tone which may be

tones, the harmonics of the fundamental tone, its octave, fifth above or twelfth, its double octave, and third above that, or seventeenth.

drawn out of a disk produces its own characteristic nodal lines or figures. (See Chladni's "Acoustics.")—Tones may differ not only in the velocity of their succeeding waves, but also in the form of these waves; this determines the character of the tone which the French call *timbre*. By it we distinguish the sounds of different instruments, the voices of different persons, &c. Comparative physiology has determined which special portions of the interior structure of the ear are intended for the different functions in the act of hearing, by finding some parts more or less developed in proportion as the animal possesses the capacity of distinguishing variations of sound. So the dog, with no musical ear, distinguishes the voice of his master better than those singing birds which can learn a tune and thus have a musical ear. (See EAR.) Recently experimenters have succeeded in causing sounds to draw waving lines on slips of moving paper, these waves representing not only the pitch or velocity of vibrations, but by their different forms also the nature of the sounds. In our figures are represented a few illustrations of

Sound Lines traced on Paper by the Phonautograph.

the waved lines produced by this method of registering the nature of diverse vibrations of the same length and pitch. The apparatus with which this is performed is called a phonautograph.—In regard to the application of acoustics to architecture, and the construction of buildings intended for music or public speaking, much learning has been erroneously applied. The elliptical and parabolic forms given to walls or ceilings have not answered expectation, for the simple reason that they concentrate the sound at single points at the expense of others. Experience has however taught a few facts, of which the most important is that an echo is the greatest disturbing influence, and that large smooth walls and ceilings at a distance from the speaker make this disturbance a maximum. Speakers, singers, or musical instruments must therefore be placed as near to such a wall as practicable; and when a high flat or arched ceiling causes reflection or re-

verberation of sound, as is often the case in large churches, a horizontal sounding board of some 20 or more feet in diameter, thus projecting far beyond the pulpit, and placed as low as possible, only a few feet above the speaker's head, has been found the only effective remedy. It is seen in most of the cathedrals and large churches on the European continent.—Among the earlier writers and investigators must be mentioned Euler, Newton, Laplace, Chladni, and Savart; and among the later, Helmholtz, Weber, König, Herschel, Wülner, and Tyndall. See especially Helmholtz, *Die Lehre von den Tonempfindungen* (Brunswick, 2d ed., 1865); Tyndall, "Lectures on Sound;" Peirce, "On Sound," prepared from Herschel's writings; and Wülner, *Experimentalphysik* (Leipsic, 1871, vol. i.).

ACQUAVIVA, Claudio de, a general of the Jesuits, born in Italy in 1542, died in 1615. He regulated the studies of the order of Jesuits in an ordinance promulgated at Rome in 1586, which became famous under the title of *Ratio Studiorum*. He prohibited discussions on the subject of tyrannicide, and his opinions are still regarded as authoritative by the order.

ACQUAVIVA DELLE FONTI, a town of S. Italy, province of Terra di Bari, 18 m. S. of Bari; pop. in 1861, 6,517. It is surrounded by walls, and has a handsome parish church.

ACQUI (anc. *Aque Statiellæ*), a town of Italy, capital of a district of the same name, in the Piedmontese province of Alessandria, on the left bank of the Bormida, 18 m. S. of Alessandria; pop. about 9,000. It is much frequented by invalids for its famous hot sulphur springs, which were well known to the ancient Romans. The remains of a Roman aqueduct are among its curiosities. It contains many handsome buildings, among them a cathedral, convents, a college, and a theological seminary.

ACRE (Lat. *ager*, Ger. *acker*, a cultivated field), a standard measure of land, consisting in England and the United States of 4,840 square yards, or 43,564 square feet. In surveying, it is composed of 10 square chains, the measuring chain being 66 feet long. There are 640 acres in an English statute square mile. The Scotch acre is 1·27 of the English, and the Irish 1·62; the French and Belgian hectare, 2·47, and the arpent 0·99 (Geneva, 1·27); the Swiss faux, 1·62; the Spanish fanegada, 1·06; the Portuguese gueira, 1·43; the Austrian joch, 1·42; the Danish toend, 5·50; the Swedish tunneland, 1·13; the Russian desiatina, 2·70. The morgen of Germany is generally about 0·65 of an acre, but it has heretofore varied in the different states from 0·63 to 2·40; in Holland it is 2·10, and in Poland 1·38. The moggia of Naples is 0·83 of an acre; the giornate of Sardinia, 0·93; the saccata of Tuscany, 1·22. The ancient Roman jugerum was 0·66 of an acre, and the Greek plethron 0·23.

ACRE, or **St. Jean d'Acre** (called *Acca* by the Turks, *Accho* in Scripture, and *Ace* and *Ptolemais* by the Greeks), a seaport town of Syria,

St. Jean d'Acre.

N. of Mt. Carmel, 64 m. S. of Beyrout, in lat. $32^{\circ} 54' N.$, lon. $35^{\circ} 4' E.$; pop. about 5,000. It is on an almost triangular peninsula, and on the land side is surrounded with beautiful new fortifications; remains of the old fortifications still project from the sea. Its harbor is the best on that part of the coast, although very shallow. The place is of the highest antiquity, mentioned in the history of the Jews, Persians, and Ptolemies, and is renowned for its desperate sieges and defences. In 1104 it was taken by the Genoese, from whom Saladin retook it in 1187. The assault upon it by Richard Cœur de Lion in 1191 was one of the most daring feats in the crusades. After its capture by the Christians in that year, it remained in the custody of the knights of St. John, who fortified it strongly, till 1291, when they were compelled to evacuate it by the sultan of Egypt. The Turks occupied it early in the 16th century. In 1799, supported by Sidney Smith and a few British sailors, they kept Bonaparte and the French army at bay for 60 days, when he raised the siege and retreated. In 1832, when Mehemet Ali revolted from the Porte and seized upon Syria, Ibrahim Pasha, after a long siege, took Acre by storm. In 1839 Syria was restored to Turkey, but Ibrahim refused to evacuate Acre till after a bombardment by the combined British, Austrian, and Turkish squadrons, Nov. 4, 1840.

ACRELIUS, Israel, a Swedish clergyman, born Dec. 25, 1714, died April 25, 1800. He studied in Upsal, and was ordained in 1743. In 1749 he was appointed provost of the Swedish congregations on the Delaware, and pastor of Racoon and Pensneck, and subsequently of Christiana. He managed the ecclesiastical affairs of the Swedish colonists, which he found

in great disorder, with zeal and prudence. Ill health, however, compelled him to resign his situation in 1756, and return to Sweden. The king bestowed upon him a large pension, and the lucrative living of Fellingsbro. Besides some articles on American affairs in the Swedish journals, and numerous religious works, Acrelius published a description of the Swedish colonies in America (4to, 1759).

ACROCERAUNIA (Gr. *ἄκρον*, peak, and *κεραυνός*, thunderbolt), in ancient geography, the N. W. extremity (now Cape Linguetta) of the Ceraunian mountains in Epirus, so called from its being often struck by lightning. The name is sometimes improperly applied to the whole range. (See **CERAUNIAN MOUNTAINS**.)

ACROPOLIS (Gr.), the highest point of a city, or its citadel, usually on a rock or hill. The ruins of the most celebrated, that of Athens, still exist for the delight of travellers. It had five gates, the principal a splendid structure of Pentellican marble, and within its bounds still stands the Parthenon or temple of Minerva.

ACT. See **BILL**.

ACTA DIURNA (Lat., daily doings), the name of daily reports issued in ancient Rome, chiefly under the empire. They were published by authority, and contained a brief chronicle of the proceedings at public assemblies, and in the tribunals both civil and criminal, together with a register of births, deaths, marriages, and some other interesting matter. Divorces, being matter of scandal, were a staple item of domestic intelligence in an age when printing was unknown. The circulation must have been very limited, and the transcripts chiefly for the use of the patricians. Reporters (*actuarii*) were employed to procure interesting news not to be found in official registers.

ACTÆON, in Greek mythology, a hunter, grandson of Cadmus, who, for the crime of watching Diana while bathing, was transformed into a stag, and devoured by his own hounds.

ACTA ERUDITORUM (the transactions of the learned), the title of the first literary journal of Germany, founded in 1682 by Otto Meneke, professor in the university of Leipsic, and several associates, and published monthly in Latin. It remained in the hands of the Meneke family and preserved its reputation until, in 1754, it fell under the charge of Professor Bel, who managed it so negligently that it lost character and circulation. The calamities of the seven years' war also operated against it, and it languished till 1782, when the last volume appeared, which, however, only brought up the review to 1776. The whole collection is contained in 117 vols. 4to. In 1782 the title was changed to *Nova Acta Eruditorum*. The work having met the approbation of the critics of foreign countries, and its convenience being undeniable, a numerous race of imitators soon sprung up in France, Germany, and England.

ACTA SANCTORUM, *Acta Martyrum*, **Martyrology**. The ancient church gave the name *Acta Martyrum*, or "Acts of the Martyrs," to the records of the lives and sufferings of the martyrs which were kept for the edification of the faithful. The oldest acts extant are those referring to the death of St. Ignatius of Antioch (107). When to the lives of the martyrs those of other pious men were added, the collections received the name *Acta Sanctorum*, "Acts of the Saints." The deaths of pious men, and the circumstances attending their death, being communicated by the various Christian congregations to each other, an alphabetical list was occasionally hung up in the churches to keep their names fresh in the recollection of the brethren. These lists grew into brief biographies, and at length the institution of canonization and the dedication of particular days to the memory of the saints introduced their names and histories into the breviary and missal. The oldest collection of the acts of the martyrs was compiled by the church historian Eusebius in his two works *De Martyribus Palestinæ* and *Synagoge Martyriorum*. Collections of the most important lives were made in the 6th century by Gregory of Tours, and in the 10th by Simeon Metaphrastes. A more critical treatment is found in the *Sanctuarium* of Boninus Mombritius, and particularly in Ruinart's *Acta Martyrum Sincera* (fol., Paris, 1689). By far the most celebrated collection of the lives of saints is that commenced by the Jesuit Bolland (died 1665), and still continued by a society of Jesuits, called Bollandists. In fact, this collection is so much more important than any other work of the kind, that in the history of literature it alone is understood by the name *Acta Sanctorum*. (See BOLLAND.)

ACTIAN GAMES, in Roman antiquity, solemn games instituted by Augustus in memory of

his victory over Mark Antony at Actium, 31 B. C., held every fifth year, and celebrated in honor of Apollo, surnamed Actius.

ACTINIA (Gr. *ἀκτίς*, ray), a genus of marine radiated animals, commonly called sea anemones, from their resemblance to flowers. They are fleshy polyps, termed *zoanthoria* by De Blainville, and *zoophyta helianthoidea* by Dr. Johnston. The body is regular and somewhat like a flower in form, more or less elongated and very contractile, enabling it to assume a great variety of shapes. It has a sac-shaped digestive apparatus, with an oval orifice, surrounded by tubular tentacles of various forms. In many species the base of the body acts as a sucker, by means of which they adhere to rocks, stones, &c., while the opposite

Metridium marginatum (Fringed Actinia), expanded.

Metridium marginatum, closed.

extremity presents a disk with a central orifice. This is surrounded by tentacles either in a single row or in several rows, which act as so many arms by which the animal seizes its prey and drags it into his mouth. Its only organ, the stomach, performs almost all the functions of animal life; this has, besides its opening from the mouth, one at the bottom communicating with the general cavity of the body, which may be shut at will, making a closed sac where digestion is rapidly performed by means of active secretions. The lower cavity is divided by folds running from the circumference toward the centre, from top to bottom of the animal, the food circulating freely among these partitions by the action of vibratory cilia on their walls. Digestion is

here combined with a kind of circulation; they have no blood, no vessels, no respiration other than that effected by the currents of water in the interior, doubtless accompanied by a change of substance. The surface of the tentacles is thickly studded with microscopic vibratile cilia in constant motion, causing currents which bring to them their microscopic food, sweeping a space of several inches. Each tentacle is a tube, with longitudinal and circular fibres, by which it can be shortened, lengthened, and moved in all directions. Upon the tentacles are great numbers of microscopic so-called "lasso cells," each containing a long hollow thread coiled spirally within it, which can be suddenly thrust out, benumbing and arresting shrimps and small fish incautiously venturing too near these innumerable and invisible threads, and enabling the tentacles to seize and convey them to the central mouth. Similarly armed threads may also be projected from the sides of the body. The eggs are very numerous, being in bunches on the inside of the partitions until ready to be hatched, when they escape through the stomach and mouth, or through the tentacles, into the water, giving

Anthea Cereus (Opelet).

rise to creatures like themselves, only with fewer tentacles, which are in multiples of five. The young one has only five, one in the line of the mouth and the others in two pairs laterally; so that even here there is an indication of bilateral symmetry, with definition of anterior and posterior regions. The actinia is the type of the single polyp, as distinguished from the compound coral polyps. It preys voraciously on small crabs and mollusks, and when waiting for its victims these arms are expanded like the petals of a flower, and, being tinted with very brilliant colors, they present an elegant appearance. The actinia seizes animals apparently superior in strength and bulk, engulfs them in its sac or stomach, and distending itself to a great degree, digests them rapidly, disgorging the shells and harder parts of the victim when the softer parts have been consumed. Some actiniae are fixed, and others are free. The external tunic of the body presents both longitudinal and transverse muscular fibres, covered by a layer of skin or mucous membrane. Nervous fibres have also been detected, and the sensibility of the animal is extreme; they contract even when a dark cloud

passes over them. They may be seen at low water, clustered upon rocks and masses of stone, which they cover, as with flowers. There they remain tenaciously adhering by their base. They are, however, capable of moving from one spot to another; and in winter they seek deeper water, where the changes of temperature do not affect them.—The sea anemone is very common on the southern shores of England and on the New England coasts; and one species (*actinia Jordaica*), on the shores of the Mediterranean, is esteemed a great delicacy by the Italians. The fringed actinia (*metridium*), the most common on the N. E. coast of North America, is, in large specimens, about 4 inches high and 3 inches across the expanded disk. They are found of various colors, pink, brown, purple, whitish, and orange, in pools among the rocks, flooded at high tide, and overhung by seaweeds. In *anthea cereus*, of the British coast, there is no power of retracting the long tentacles within the body; the body is of a light chestnut color, and the numerous tentacles usually sea-green tipped with red. It is of about the size of our fringed actinia.—See "British Sea Anemones," by Philip Henry Gosse (London, 1860), and "Coral and Coral Islands," by James D. Dana (New York, 1872).

ACTINISM (Gr. *ἀκτίς*, a ray of light), the peculiar property or force of that portion of the sun's rays which produces the chemical effects shown in photography. That the actinic rays are different from those which produce heat and light was shown as far back as 1842 by Prof. J. W. Draper of New York, who recognized in them a new principle or force, for which he proposed the name of tithonicity, and for the rays that of tithonic. The name now adopted was given by Mr. R. Hunt of England. It is found that actinism does not exist in the most luminous rays of light, and that these rays actually tend to prevent the peculiar effects of this force upon inorganic matter. The quantity of actinism in the sun's rays varies with the time of day and with the seasons. It is intercepted by red, orange, and yellow glass; hence photographers now use glass of these colors to admit light to their so-called dark rooms. Such glass transmits the solar heat, while blue and violet glass, which transmit little or nothing of this heat, transmit the actinic rays. The reason of this has been explained by experiments in taking photographs of the solar spectrum; they proved that no actinism exists in the red, orange, and yellow rays, that it commences feebly in the green, becomes stronger in the blue, and is strongest in the violet; but what is remarkable, it is also found to extend far beyond the latter color, in the dark space entirely outside the visible spectrum. In photographing the spectroscopic lines, it is found that this dark space contains scores of them as well as the visible part of the spectrum, and it appears that the only reason that we do not see these ultra-actinic rays

is that the liquids in our eyes cannot transmit waves of such great velocity; when this velocity is decreased by throwing the spectrum on some fluorescent substance, as paper, painted with a solution of quinine, or on uranium glass, the lines may be rendered visible. The so-called fluorescent substances reduce the velocity of the luminous waves falling on them; in fact, they emit luminous waves of a less velocity than those by which they are illuminated. Mr. Rutherford of New York has made the most elaborate photographs of all the lines in the actinic portion of the solar spectrum, the invisible as well as the visible, to the number of several thousand. A few of these lines are represented in the spectrum given here, of

Curves representing the comparative intensity of the luminous and actinic rays in different parts of the solar spectrum.

which only the portion from A to H is visible, while that from H to P is invisible, but may be photographed, even to a further extent than is here represented. The height of the unshaded curve below represents the intensity of the light in the corresponding portion above, while the height of the shaded curve represents the intensity of the actinic action. It is seen that while the strongest light is in the yellow between the lines D and E, there is a total absence of actinism here; the strongest actinism is found near the lines H, where there is scarcely any light left, so that the spectrum dwindles down in darkness at that spot, while this actinism extends about twice the length of the visible spectrum.—In regard to the asserted action of the actinic rays on germination and the growth of plants, the most conscientious experiments have proved that only darkness promotes germination, and that plants want for their growth not that light alone from which the heated rays have been eliminated by passing it through blue or violet glass. Such glass cannot increase the actinic power, but only decrease the light and heat, and experience has shown that most plants suffer decidedly by such treatment; that the green coloring matter of the leaves, of which the chlorophylline is the most important, needs the red rays for its promotion; and that all plants must, in order to

prosper, have the benefit of the full unadulterated solar light.

ACTINOMETER, the name generally but improperly applied to a thermometer intended to measure the heat of the solar rays. The first so-called actinometer was made by Sir John Herschel in 1825, and consisted of a thermometer with a large bulb filled with the blue solution of the ammonia sulphate of copper, enclosed in a box with plate glass on top. When exposed to the sun's rays the expansion of the liquid indicates their intensity. The instrument is nearly identical in its results with that of Pouillet, which he calls pyrheliometer. Recently an ordinary mercurial thermometer enclosed in a box, and used alternately in the shade and in sunshine, was described by the Rev. Mr. Hodgkinson under the name of actinometer.—A true actinometer is an instrument to measure the actinic or chemical power of the solar rays. The first contrivance to effect this object was the darkening of a surface sensitized by chloride of silver. The difficulty here was to make a preparation which was always uniformly sensitive. Dr. John W. Draper of New York discovered the important fact that of a mixture of equal volumes of chlorine and hydrogen, the amount combining to form chlorhydric acid is directly proportional to the actinic intensity of the light and the time of exposure. He made use of this property for the purpose of practical actinometry; while recently Bunsen and Roscoe have devised an actinometer based on the very same principle, and giving results of the most absolute scientific accuracy. There are, however, many other actions of this kind known in chemistry which may be more conveniently employed. A solution of chloride of gold and oxalic acid will remain clear in the dark, while gold is precipitated by exposure to actinic rays, the amount of gold being proportional to the intensity of the rays and the time of exposure. See "Philosophical Transactions," 1859, p. 879; 1852, p. 139.

ACTION, the formal demand of one's right from another in a court. In the Roman law action is defined to be either the right which one has of seeking in a judicial tribunal that which is his due, or the pursuit itself, or the exercise of the right. In our law the pursuit of the remedy is properly the action, and the right on which it rests is the cause of action. In its usual sense the word describes all the proceedings incident to the demand of the right, including the adjudication of the court upon it.—As actions are appeals to the supreme power of the state, to decide upon the matters in controversy between the parties, they are, except where recent reforms in procedure have changed the practice, commenced by writs issued out of courts, in the name of the sovereign, or of the judges as his representatives, calling upon the defendant to come into court and answer. Such writs still remain in many of the states and in most of the courts of the

United States. But in New York, and other states which have imitated its procedure, the action is commenced by a simple notice or summons signed by the plaintiff or his attorneys; though it is not to be understood that the theory of the action, as invoking or setting in motion the sovereign power of the state, is in any respect changed.—The New York code defines an action as an ordinary proceeding in a court of justice, by which one party prosecutes another party for the enforcement or protection of a right, the redress or prevention of a wrong, or the punishment of a public offence. This definition suggests the chief division of actions, namely, into civil and criminal actions. A civil action may be brought by a private person; but in criminal actions in the proper sense, namely, proceedings for the punishment of crimes, the state or the people, that is, the sovereign power, is the plaintiff or prosecutor. An individual can sustain an action which relates to a criminal offence only when he has suffered from it some injury peculiar to himself. Thus no private person, but only the people, can bring an action for a public nuisance; but if the public wrong inflicts a special injury on the individual, he may have his private action for that. In respect to the higher grades of criminal offences, it is the general principle at least of the law, though no very certain rule about the matter can be given, especially with reference to the American law, that the private remedy for the especial injury must be postponed until after the individual has done his duty to the public by setting afoot a public prosecution of the crime.—It is said, in general terms, that for every wrong the law provides a remedy by action; and, rightly understood, this is true. But there is not a remedy or action for every injury. It is only for those acts which are injuries in the estimation of the law, or, in other words, which are wrongs in a legal sense, that the law gives redress by actions. As the Latin phrase is, there may be *damnum absque injuria*, that is to say, damage or injury, but yet no legal wrong. So where the harmful act is done by one in the exercise of a function or authority conferred by the sovereign power, and within its limits, and without any fault on his part or for his personal benefit, no action lies against him for the injury. Thus no action will lie against a judge of a court of record for an act done by him in the exercise of his judicial office; and this is true even if he acts without jurisdiction in fact, unless he knew, or had the means of knowing and so ought to have known, the defect of jurisdiction; and it lies upon the plaintiff in any such case to prove these essential facts. This principle applies to the case of all persons intrusted with the performance of public duties or functions, and exercising them without any personal emolument, who, without malice, negligence, or other fault in the exercise of such duties, inflict injury upon individuals.—No action can be maintained by

a citizen against a sovereign without its express consent; therefore, as a rule, no suit can be brought by an individual against the state or the United States. Causes of action against these must be presented by petition or some proceeding of that character. The United States receives demands of this character in its court of claims. Nor will the courts of a state ordinarily entertain actions against foreign states or sovereigns, for anything done or omitted by them in their public character. Claims of this sort are properly the province of diplomatic negotiation.—As injuries are numerous and various, so the character and forms of actions are manifold. Many of the old-fashioned forms, which made certain technical tests essential to their maintenance, have been wisely abolished. It has been attempted in New York to get rid of all distinctive forms. There, every other than a criminal action is a civil action. There is no other or specific name for it, and the design of the code is to give by this single action every kind of remedy or relief which can be sought in civil causes. But the characteristics of the old forms of actions remain, nevertheless, and as they must, they still determine the forms of the one action; so that its characteristic shapes are almost as numerous as the old forms of which it has extinguished the names.

ACTUM (now *La Punta*), a promontory and village in Acarnania, at the entrance of the Ambracian gulf, near which Octavius, afterward Augustus, vanquished Mark Antony, Sept. 2, 31 B. C., in a great naval engagement which decided the question of universal dominion, and made the victor emperor. The generals had nearly equal armies on opposite sides of the bay, but these took no part in the combat. Octavius had 260 ships, Antony 220. Cleopatra reinforced Antony with 60 ships, and he imprudently offered a naval battle to Octavius. Agrippa, the admiral of Octavius, by a rapid manoeuvre, soon put to flight Cleopatra with her galleys. The voluptuous Antony followed her with a few ships. His fleet, deserted by its leader, surrendered, and his army did the like after waiting seven days for his return.

ACTON, Sir John Francis Edward, Neapolitan prime minister, born in 1736, died in Palermo, Aug. 12, 1811. He has been often erroneously called Joseph, the name of his brother. His immediate ancestors were London merchants, descendants of an English country gentleman, Edward Acton, who was created a baronet on account of his fidelity to Charles I. Sir John, who inherited the title in 1791, was in the naval service successively of France, Tuscany, and Naples, where he became a favorite of Queen Caroline, and rose rapidly to the post of premier of King Ferdinand. He had intimate relations with the English ambassador and his wife, Sir William and Lady Hamilton, and was an inveterate enemy of the French revolution. His administration was despotic and cruel. In 1798 he accompanied King Ferdinand in

the expedition of the Austrian General Mack against the French. He lost his prestige after the disastrous result of the campaign, and was finally in 1806 ousted from power.—His second son, CHARLES JANARIUS EDWARD (1803-'47), became a cardinal in 1842. Sir John's brother, JOSEPH EDWARD, was a lieutenant general in the Neapolitan service, and became the progenitor of several distinguished naval officers; and the Italian minister of marine in 1869-'70, Rear Admiral GEORGE ACTON, and several other officers of the present day, residents of Naples, are members of the same family. Sir John Francis Edward Acton was succeeded as 7th baronet by his son FERDINAND RICHARD EDWARD (1801-'87), who married in Paris in 1832 the only child of the duke of Dalberg, and assumed the name of Dalberg-Acton. His widow became in 1840 the wife of the present Earl Granville, and died in 1860.—Sir JOHN EMERIE EDWARD DALBERG-ACTON, born Jan. 10, 1834, studied from 1850 to 1854 at the university of Munich, made then with his stepfather Lord Granville a tour through the United States, and married in 1865 a daughter of Count Arco-Valley of Munich. He founded in 1861 the "Home and Foreign Review," an organ of the liberal Catholics, and edited in 1863 *Matinées royales*, a work ascribed to Frederick the Great, in regard to which there has been much controversy in Germany. In 1870 he took an active part in the Old Catholic movement, and has published in its support, in the German language, *Zur Geschichte des vaticanischen Concils* (Munich, 1871). He was in 1860 elected member of parliament for Carlow, Ireland; and again, as candidate of the liberal party, in 1865 for Bridgnorth, England. In 1869 he was made a peer as Baron Acton.

ACTON BURNELL, an English statute, so named because the parliament at which it was passed was held at Acton Burnell, a little village in Shropshire. The date of the statute is Oct. 12, 1283. It is the first statute passed in England enabling merchants to recover debts due to them, and is therefore often called *Statutum Mercatorum*, or statute of the merchants. By it the mayor or the sheriff might seize and sell the chattels and lands of the debtor, or, if he had no effects, might detain him in prison until the debt was paid, feeding him meanwhile on bread and water if he was too poor to support himself, maintenance money to be added to the original debt. The statute of Acton Burnell met with much opposition from the sheriffs. The Jews were excluded from the benefits of this liberal statute, which was passed to encourage the settlement of foreign merchants in England. Barrington states that a similar ordinance was not passed in France till 1536, in the reign of Francis I. The statute of merchants is considered an epoch in the social history of the middle class of England, and indicated their growing power.

ACTS OF THE APOSTLES, the fifth book of the New Testament, and the last of those prop-

erly historical. It is recognized on all sides that the Acts were written by the same author as the third Gospel, and the early tradition of the church was firm and constant in ascribing them to Luke. Schleiermacher regarded the book as an aggregate of various reports by different writers, and ascribed the most important of these works, the writer of which is characterized by the use of the word *we*, to Timothy. This view was supported by De Wette, Bleek, and other critics. Mayrhoth (1835) ascribed the whole book to Timothy, while Schwanbeck (*Ueber die Quellen der Schriften des Lukas*, 1847) assumed Silas to be the author. The authenticity and canonical character of the book was in the ancient church only denied by a few heretical sects, such as the Ebionites and Manichæans, whose objections were entirely of a dogmatical, not of an historical character. Chrysostom, however, complains that even in his time the book was not so much as known. In modern times the critics of the Tübingen school, in particular Baur, Zeller, and Schwegler, assumed the book to have been written in the course of the 2d century. Those who assert the authorship of Luke, including Renan, variously fix the time of writing between 58 and 80. The author clearly indicates that for the materials of the latter part of the book (xvi. 11 to xxviii. 31) he has drawn upon his own recollection or upon that of the apostle Paul. For the first part the author is believed by some writers of the critical school to have made use of older writings, and in particular of the apocryphal book entitled "Preaching of Peter."—As regards the design of the Acts, it has long been a prevalent opinion that Luke intended to follow up his history of the life of Christ by a narrative of the establishment and early progress of the Christian religion. The opinion of Hugo Grotius that this book was intended to trace the lives of the two chief apostles, Peter and Paul, has found many supporters among the theologians. According to Schneckenburger, whose *Ueber den Zweck der Apostelgeschichte* (1841) is the first important work on the subject from the standpoint of the critical German school, the author wished to write an apology of Paul against his Judaizing opponents, and to prove that he was in no point inferior to any of the other apostles, and in particular to Peter. This theory was somewhat modified by Baur, the chief of the Tübingen school, who undertook to show that the Acts had been compiled in the 2d century for the purpose of effecting a reconciliation of Petrine and Pauline Christianity. The most important work of the Tübingen school on the subject is that of Zeller, *Die Apostelgeschichte nach ihrem Inhalt und Ursprung kritisch untersucht* (1854), which regards the Acts as a book proceeding from the Pagan-Christian party, and intended to purchase the peace of the church by some concessions to the Judaizing Christians. The inspired character of the book has been defended

against the Tübingen school by Lange, Thiersch, Ebrard, Schaff, and others; and even writers like Bleek, De Wette, and Renan defend the trustworthy character of the Acts as a work of history. The style is purer than that of most other books of the New Testament; the first part, however, contains a considerable number of Hebraisms. The Acts include the history of the Christian church from the day of Pentecost to the imprisonment of Paul at Rome. With regard to the dates of the principal events recorded, there is a wide difference of opinion. (See *PART.*) Besides the works on the Acts already mentioned, those by Lekebusch (*Die Composition und Entstehung der Apostelgeschichte*, 1854) and by Trip (*Paulus nach der Apostelgeschichte*, 1866) are of special importance.

ACUÑA, Cristobal de, a Spanish Jesuit missionary in Chili and Peru, born at Burgos in 1597. He was one of the early explorers of the Amazons, being attached to Texeira's expedition to that river (1639-41), with the special object of reporting the incidents of the exploration. Acuña returned to Spain with an interesting narrative of it, which he published at Madrid; but the distraction of the country prevented the government from taking any interest in the colonization of the region to which so much energy and talent had been devoted. He once more went to South America, and died on a journey from Panama to Lima.

ACUPUNCTURE (Lat. *acus*, a needle, and *pungere*, to prick), an operation introduced by the Chinese, who imagine that it gives vent to acrid vapors. The needles employed by them are of gold or silver, manufactured under special license from the emperor, and their use forms a distinct branch of medical practice. Introduced into Europe in the early part of this century, the operation is now but seldom performed except to give issue to fluids in dropsy, &c. It is advocated by some in the treatment of neuralgia, especially sciatic, and in muscular rheumatism, acting in these cases as a counter-irritant. The needles used are of steel, 2 to 4 inches long. Usually but one is inserted, though sometimes as many as 20 or 30. They are introduced to a depth of one to two inches by simple pressure, by pressure with rotation, or by percussion. The length of time during which they are allowed to remain varies from a minute to several days. Instances are known where they have been passed with impunity through vital organs. Infanticide by acupuncture of the brain or spinal cord is a well recognized crime.

ADA, a S. W. county of Idaho, separated from Oregon by the Snake river (here also called the Saptin); area, about 2,800 sq. m.; pop. in 1870, 2,675. The county was organized in 1864. Mining is the principal occupation of the people. The total value of property in 1869 was \$1,014,185. There are three newspapers. Capital, BoisÉ City, which is also the capital of the territory.

ADAIR. I. A S. county of Kentucky, intersected by Green river; area, 450 sq. m.; pop. in 1870, 11,065, of whom 1,836 were colored. The surface is hilly and abounds in good timber, and the soil is moderately fertile. The productions in 1860 were 29,513 bushels of wheat, 413,205 of corn, 24,195 of oats, and 767,395 lbs. of tobacco. Water power is abundant and several manufactories are in operation. Capital, Columbia. **II.** A N. N. E. county of Missouri, intersected by Chariton river; area, 570 sq. m.; pop. in 1870, 11,448, of whom 143 were colored. The land is undulating prairie, suited to the production of grass and grain. In 1860, 554,835 bushels of corn and 84,353 lbs. of tobacco were produced. Capital, Kirksville. **III.** A S. W. county of Iowa; area, 576 sq. m.; pop. in 1870, 3,982. Middle river, an affluent of the Des Moines, and the head streams of Nodaway river, run through it. The state road from Fort Des Moines to Council Bluffs also traverses the county. Capital, Fontanelle.

ADAIR, Sir Robert, a British diplomatist, born in London, May 24, 1763, died Oct. 3, 1855. His father, Robert Adair, was sergeant-surgeon to George III. He was distantly related to Charles James Fox, and was early destined for a political career. He entered parliament in 1802, and was a strenuous supporter of whig politics. In 1806 Mr. Fox sent him as ambassador to Vienna, and in 1808 Mr. Canning, although opposed to him in politics, sent him on a special mission to Turkey, where he negotiated the treaty of the Dardanelles, concluded in 1809. He remained at Constantinople till 1811, having been appointed ambassador in 1809. Sir Robert Adair afterward remained out of office till 1831, when Lord Grey sent him to Belgium, soon after the erection of that country into a kingdom, and he was prominent in negotiating peace. He retired from this mission with the rank of privy councillor in 1835. He left memoirs of his residence at St. Petersburg and Vienna, written at the age of 82.

ADAL, or **Adel**, a portion of the E. coast of Africa, between the Abyssinian highlands and the Red sea, and extending from the bay of Tajurra to Cape Bab-el-Mandeb, and from thence 300 m. along the shore of the Red sea to the town and harbor of Massowah; lat. 11° 30' to 15° 40' N. It is inhabited by the Danakil or Affar, a Mohammedan nation, from the most famous tribe of which, Ad Alli or Adaiel, its name is derived. The territory of Adal varies from 120 m. wide at the bay of Tajurra, to only 40 m. opposite Annesley bay. There is a low tract along the coast, which rises gradually to a height of 2,000 feet above the sea in a distance of 25 or 30 m., and then the ascent is very rapid to the table land of Tigré. On the highest terraces durra and barley are cultivated in small patches. Camels, mules, asses, goats, and sheep abound, the pasturage is generally good, and large quantities of butter are annually sent to Massowah, and thence

to Arabia. Wild animals are numerous, and even the lion and elephant are occasionally seen. A large plain, called Harho, is covered with salt three feet thick, which is not only used for culinary purposes, but in Abyssinia as a currency. Adal is peopled by many tribes, which appear to belong to the same stock. They are of a dark brown color, muscular and full in body, with roundish face, thick crisp black hair, lively eyes, lips thinner than those of the negroes, and short straight nose, divided from the forehead by an indentation. They all live a nomadic life, travelling with their flocks and herds from pasture to pasture. The sultan of the Adal resides at Tadjura, and the sultan of the Mudaito Danakil at Aussa, near the Hawash, 80 m. W. by S. of Tadjura. Salt is the only commodity exported.

ADALBERT. I. Or *Aldebert*, a Frankish bishop and missionary to the German pagans before the middle of the 8th century. He was accused of heresy by St. Boniface, who charged him among other things with collecting his own hair and nails as relics. He was condemned by a synod held in 745, and died in prison. His disciples were styled Adalbertines, or Aldebertines. **II.** *Saint*, of Prague, "the apostle of the Prussians," died in 997. He was educated by the celebrated Othrich at Magdeburg. In 983 he was chosen bishop of Prague. Discouraged at his failure to convert the Bohemians, he repaired to the monastery of St. Alexius at Rome. In 993 he was recalled to his bishopric, but after two years became again disgusted and left. In 995 he baptized the future St. Stephen and first king of the Hungarians at Gran. He subsequently went to Poland, and thence to Prussia, to convert the heathen, by whom he was murdered. **III.** Archbishop of Bremen and Hamburg, died at Goslar, March 17, 1072. He received his office in 1043 from Henry III., whom in 1046 he accompanied to Rome. There he was a candidate for the papal throne, and barely failed in the election. Pope Leo IX., in whose behalf he had spoken in the synod at Mayence in 1049, made him in 1050 his legate in the north. During the minority of the emperor Henry IV. he usurped, together with Archbishop Hanno of Cologne, the administration of the empire. He became so obnoxious to the German princes, that in 1066 they forcibly separated him from the emperor; but in 1069 he regained his power, and kept it till his death.

ADALBERT, Heinrich Wilhelm, a Prussian prince, first cousin of the emperor William, commander-in-chief of the German navy, born Oct. 29, 1811. He travelled in Europe, the East, and Brazil, and printed privately *Aus meinem Reisetagebuch* (Berlin, 1847), which has been translated and published in English (London, 1848). He holds high military rank, but has devoted himself to naval affairs, and in 1854 was made admiral. In 1856 he commanded the Prussian corvette Danzig on the expedition against the Riff pirates; but as the

Prussians numbered only 90 and the pirates 500, he was obliged to retire, losing 24 killed and wounded, and being himself shot through the thigh. In 1864, during the Danish war, he cruised with his fleet in the Baltic, and at its close he was appointed commander-in-chief of the national navy. In 1870 he visited the English seaports with a squadron. During the Franco-German war his ships took refuge in Wilhelmshaven, and he observed the war at the German headquarters.—His wife, **THERESA ELSSLER**, sister of the celebrated Fanny, and herself a skilful dancer, received the title of baroness von Barnim on hismorganatic marriage with her in 1850. The only offspring of this union, **Baron ADALBERT VON BARNIM**, born in 1841, died July 12, 1860, in Egypt. The scientific observations made during his journey to that country were published after his death by Dr. Hartmann, his physician (*Reise des Freiherrn A. von Barnim durch Nordost-Afrika*, Berlin, 1865).

ADALIA, or *Sattalieh* (anc. *Attalia* in Pamphylia), a seaport and the largest town on the S. coast of Asia Minor, on the gulf of Adalia, 250 m. S. E. of Smyrna; pop. about 12,000, of whom 3,000 are Greeks. It is the capital of a pashalic. The town is built in the form of an amphitheatre, the ground rising to the height of about 70 feet above the sea, and is surrounded by a double wall with square towers about 50 yards apart. The chief trade is in wool, cotton, and opium. There are some important ancient remains.

ADAM, the first man, the husband of Eve, and father of Cain, Abel, and Seth, and of unnamed "sons and daughters." Various meanings have been ascribed to the name; the most generally recognized is earth-born. The history of Adam, in common with that of the whole antediluvian world, as contained in Genesis, is by some treated as an allegory, intended to convey to an uncultured people an intelligible idea of the world's creation, and to explain some of the momentous questions involved in this earthly being. Others contend for a literal interpretation of the narrative. For Swedenborg's doctrine on the subject, see **NEW JERUSALEM CHURCH**.

ADAM, Adolphe Charles, a French composer, born in Paris, July 24, 1803, died May 3, 1856. In 1817 he entered the conservatory in Paris, became a skilful pianist, and studied composition under Reicha and Boieldieu. His earliest compositions were fantasias and variations for the pianoforte. He wrote the opera of *Pierre et Catherine* (1829), and in 1832 composed a ballet for London. His most important work is the opera *Le Postillon de Longjumeau* (1836). His *Souvenirs d'un musicien*, with his autobiography, was published in 1857.

ADAM, Albrecht, a German painter of battle pieces, born at Nördlingen, April 16, 1786, died in Munich, Aug. 28, 1862. He studied painting at Nuremberg under Conrad Zweiger. He was engaged in the Austrian campaigns

against Napoleon, and subsequently entered the service of Eugene Beauharnais, viceroy of Italy, and painted the battle scene of Loban. He accompanied Eugene in the campaign of 1812 as far as Moscow. After the peace he prepared a series of drawings illustrative of Eugene's military career, now in the Leuchtenberg gallery, St. Petersburg. He also painted several grand battle pieces, besides his *Voyage pittoresque militaire* in 120 lithographs, illustrating the Russian campaign. He finally settled in Munich, under King Louis, for whom he painted the battle of the Moskva.

ADAM, Alexander, a Scottish teacher and grammarian, born in Murrayshire in June, 1741, died Dec. 18, 1809. He acquired learning amid difficulties, and in 1768 was appointed rector of the high school of Edinburgh, which office he filled for 40 years. He wrote "Principles of Latin and English Grammar," "Roman Antiquities," "Summary of Geography and History, both Ancient and Modern," and "Classical Biography," all of which were long in general use in Europe and America.

ADAM OF BREMEN, a German missionary and chronicler, from 1067 canon and schoolmaster at Bremen, died there about 1076. He is the author of *Historia Ecclesiastica*, which is the principal literary authority respecting the northern nations of that period. It is also called *Gesta Hammaburgensis Ecclesiæ Pontificum*, from containing a chronological record of the episcopal see of Hamburg from 788 to 1072. A part of his materials was furnished by King Sweyn Estrithson (1047-76) of Denmark. His MS. was first discovered in a Danish monastery, and published at Copenhagen in 1579. An improved and enlarged edition forms the 9th volume of Pertz's *Monumenta Germaniæ Historica*, and this became the basis of Laurent's German translation (Berlin, 1850). Adam also wrote *De Situ Daniæ* (Stockholm, 1615; Hamburg, 1706; German, Bremen, 1825). Assmussen published at Kiel, in 1834, *De Fontibus Adami Bremensis*.

ADAM DE LA HALLE, a trouvère of the 13th century, died at Naples about 1286. He was born at Arras, a town celebrated for its poets and minstrels, and was surnamed the Hunchback of Arras. He went to Naples in the suite of Robert II., count of Artois, in 1282. His pieces were not merely songs, but of a dramatic character, and he may be considered one of the founders of the French drama. His works have been published in various collections.

ADAMAWA, the Mohammedan name, while Fumbina is the pagan one, of a country of central Africa visited and described for the first time by Dr. Barth in the summer of 1851. It lies between lat. 6° 30' and 11° 30' N., and lon. 11° and 16° E. It is about 200 m. long from S.W. to N.E.; its breadth seldom exceeds 70 m. Its capital is Yola, near the N.W. border, a city of about 12,000 inhabitants, where the governor, who owes allegiance to the Foolah sultan of Sackatoo, resides. It is a Moham-

medan sub-kingdom engrafted upon a mixed stock of pagan tribes, the conquest of the valorous and fanatic Foolah chieftain Adama (whence the name Adamawa) over the great pagan kingdom of Fumbina. The governor at the time of Barth's visit was Adama's son. The native inhabitants were, however, far from being wholly subdued, several districts (especially that about Mount Alantika, 40 m. S. of Yola) being still quite independent and constantly at war. It is one of the finest countries of central Africa, irrigated by numerous rivers, such as the Benuwe, or left branch of the Quorra or Niger, and the Faro, and diversified with hill and dale. In general it is flat, rising gradually toward the south to 1,500 feet or more, and broken by separate hills or extensive groups of mountains. The grain commonly grown in the country is the *holcus sorghum*. Meat is so dear that a goat will often bring the price of a female slave. Ground nuts are plentiful. The elephant is exceedingly frequent. The most singular animal is the *ayu*, a mammal resembling a seal, living in the river, and feeding by night on the fresh grass on the river banks. There is an indigenous variety of ox, but quite a distinct species, not three feet high, of a dark gray color, called *muturu*. Excellent iron is found. The standard of value is the native cotton, woven in narrow strips called *leppi*, of about 2½ inches in width. Soap is a very important article in any country inhabited by the Foolahs, and it is prepared in every household. The Mohammedan population dress both well and decently. The pagans wear simply a narrow leathern strap between their legs and fastened on their loins. There are several Arab colonies, and Arab architects are employed by the governor. Slavery exists on an immense scale, and many private individuals own more than 1,000 slaves. The governor of Yola, who calls himself a sultan, receives every year in tribute, besides horses and cattle, 5,000 slaves. (See FOOLAHS.)

ADAMITES, a sect of the second century, who held that the merits of Christ restored them to Adamic innocence. Consequently, they appeared naked in their assemblies, and rejected marriage. They soon disappeared, but were revived in the 12th century by Tanchelin at Antwerp, who taught that fornication and adultery were meritorious, and indulged in the most disgusting brutalities in open day. One Picard also revived the sect in Germany at the beginning of the 15th century. It took root in Bohemia, where, in spite of many persecutions, it has from time to time reappeared.

ADAMS, the name of eight counties in the United States. **L. A. S.** county of Pennsylvania, on the Maryland border; area, 530 sq. m.; pop. in 1870, 30,315. The head waters of Monocacy river take their rise in this county, and small creeks abound. Along the S. border a ridge called South Mountain extends, and the general surface of the county is uneven. In the South Mountain, copper and

Potomac marble are found, and the copper mines have been worked with some success. In 1870 the personal property was valued at \$1,287,541. The crops in 1870 amounted to 494,346 bushels of wheat, 757,019 of corn, 636,828 of oats, 33,425 of rye, and 1,005,303 of potatoes. The value of animals slaughtered was \$498,545. The county has numerous manufacturing establishments. Capital, Gettysburg. **II.** A S. W. county of Mississippi, bounded W. by the Mississippi river, which separates it from Louisiana, and S. by the river Homochitto; area, 440 sq. m.; pop. in 1870, 19,084, of whom 14,287 were colored. The land is highly productive. The productions in 1870 were 177,307 bushels of corn, 26,469 of sweet potatoes, 20,140 bales of cotton, and 3,144 tons of hay. Capital, Natchez. **III.** A S. W. county of Ohio, separated from Kentucky by the Ohio river; area, 500 sq. m.; pop. in 1870, 20,750. The surface is hilly and well timbered, and the soil is fertile, and especially adapted to fruit culture. The productions in 1870 were 162,677 bushels of wheat, 156,073 of oats, 4,376 of barley, 2,123 of rye, 772,899 of corn, 39,542 of potatoes, 54,208 lbs. of wool, 434,664 of butter, and \$100,828 worth of orchard products. There were 16,333 sheep and 20,352 hogs, and the value of animals slaughtered was \$308,186. In the S. E. part of the county, near the river, are valuable quarries and iron mines. Capital, West Union. **IV.** An E. county of Indiana, bordering on Ohio; area, 324 sq. m.; pop. in 1870, 11,382. It is drained by the Wabash and St. Mary's rivers. Forests of oak, beech, ash, hickory, and elm cover a large portion of the county. The soil is productive and the surface nearly level. The productions in 1870 were 172,331 bushels of wheat, 96,168 of corn, 88,697 of oats, 12,408 tons of hay, 227,303 lbs. of butter, 32,847 of cheese, and 62,957 of wool. Capital, Decatur. **V.** A W. county of Illinois, separated from Missouri by the Mississippi river; area, 760 sq. m.; pop. in 1870, 56,362. The Quincy and Eastern and the Quincy and Chicago railroads run through the county, and the Illinois and Southern Iowa railroad forms a junction with the Quincy and Eastern within its limits. Bear creek, an affluent of the Mississippi, drains the N. W. part. The surface is undulating and covered with forests, the soil rich and to a great extent cultivated. The products in 1870 were 1,452,905 bushels of corn, 963,807 of wheat, 759,074 of oats, and 104,855 lbs. of wool. There were 26,949 sheep and 56,442 hogs. Value of animals slaughtered, \$1,103,518. There are many manufacturing establishments. Capital, Quincy. **VI.** A S. W. county of Iowa; area, 432 sq. m.; pop. in 1870, 4,614. It is drained by the Nodaway river and several of its head streams. The Burlington and Missouri River railroad runs through it. In 1870 the county produced 60,716 bushels of wheat, 253,261 of corn, 40,327 of oats, and 16,905 lbs. of wool. Capital, Quincy. **VII.** A S. central county of Wisconsin,

bounded W. and S. W. by the Wisconsin river, and drained by its affluents; area, 650 sq. m.; pop. in 1870, 6,601. Large forests cover the county, and large quantities of lumber are cut and rafted down the Wisconsin. Water power is abundant. The products in 1870 were 123,454 bushels of wheat, 114,320 of corn, 88,831 of oats, and 60,701 of rye. Capital, Quincy. **VIII.** A new county in S. Nebraska, bounded N. by the Platte river and drained by the Little Blue; pop. in 1870, 19.

ADAMS, a township of Berkshire county, Mass., on both sides of the Hoosac river; pop. in 1870, 12,090. There are four villages in the town: North Adams, South Adams, Maple Grove, and Blackington. In its vicinity are a notable natural bridge across Hudson's brook, and Saddle mountain or Mt. Greylock, which has an elevation of 3,600 feet, and is the highest point in Massachusetts. The western terminus of the Hoosac tunnel is at North Adams, and the Troy and Boston and Pittsfield and North Adams railroads terminate here. Manufactures form the leading interest. In 1865 there were in the town 11 cotton mills, with 45,072 spindles, employing 332 males and 429 females; 6 woollen mills, with 44 sets of machinery, employing 440 males and 392 females; 2 print works, printing 8,925,000 yards of calico yearly, and employing 150 males and 21 females; 4 bal-moral-skirt factories, and 2 paper mills. Two weekly newspapers and a semi-monthly are published in North Adams. The experiment of Chinese labor has recently been successfully made in North Adams. In 1870 there were 75 Chinamen employed in that village in the manufacture of boots and shoes. By the contract made in San Francisco, the Chinamen were engaged for three years. They are represented as being of quiet habits, industrious, skillful, and eager to learn in the evening schools provided for them. The town contains 35 schools, of which two are high schools.

ADAMS, Charles Baker, an American chemist and zoologist, born in Dorchester, Mass., Jan. 11, 1814, died in St. Thomas, Jan. 19, 1853. He graduated at Amherst college, and was associated with Professor Edward Hitchcock in a geological survey of New York. In 1837 he became tutor in Amherst college, and in 1838 was chosen professor of chemistry and natural history in Middlebury college, Vt., but in 1847 returned to be a professor at Amherst. In 1845, 1846, and 1847 he was engaged in a geological survey of Vermont. Between 1844 and 1851 he made journeys to Jamaica and other parts of the West Indies, for scientific purposes. He wrote "Contributions to Conchology," "Monographs of Several Species of Shells," and other treatises. Not long before his death he published a useful work on elementary geology, in which he was assisted by Professor Gray of Brooklyn.

ADAMS, Charles Francis, an American statesman, the only child of John Quincy Adams

who survived him, born in Boston, Aug. 18, 1807. At the age of two years he was taken by his father to St. Petersburg, where he passed the next six years and learned to speak Russian, German, and French. In February, 1815, he made the journey with his mother in a private carriage from St. Petersburg to Paris, to meet his father there—in the then disturbed state of Europe no slight undertaking. He accompanied his father on his mission to England, and being placed at a boarding school, according to the fisticuff usages then if not still in vogue in English schools, he was obliged to fight his English schoolfellows in defence of the honor of America. In 1817 he returned with his father to America, and was placed in the Boston Latin school, whence he entered Harvard college, where he graduated in 1825. The next two years he passed at Washington with his father, who was then president, but in 1827 returned to Massachusetts and pursued the study of the law in the office of Daniel Webster. In 1828 he was admitted to the Boston bar, but never has engaged actively in practice. In 1829 he married the youngest daughter of Peter C. Brooks, a Boston merchant—a connection which also made him a brother-in-law of Edward Everett. The next year he was nominated a representative from Boston to the Massachusetts legislature, but declined. This did not please his father, in consequence of which he accepted the nomination the next year, and served in the house for the succeeding three years, when he was transferred to the senate, in which he served two years. By this time Mr. Adams began to differ on several points with the leaders of the whig party, with which he had hitherto acted. In 1848 he was selected by the newly organized free-soil party as their candidate for the vice-presidency, along with ex-president Van Buren as candidate for the presidency. In the autumn of 1858 he was chosen a representative to Congress by the third district of Massachusetts, and took his seat in December, 1859. He was a member of the joint committee on the library, and chairman of the house committee on manufactures, which latter had but little to do, the time and thoughts of members being occupied with more exciting subjects. Mr. Adams watched with careful attention the course of events, and on the last day of May, 1860, addressed the house in a forcible speech, vindicating the policy of the republican party. In the interval between the two sessions of his congressional service, Mr. Adams, in company with Mr. Seward, made a journey in some of the northwestern states, and made several speeches in support of Mr. Lincoln for the presidency. On the day after the meeting of the second session of the thirty-sixth congress, so much of the president's message as related to the condition of the country was referred to a special committee of one from each state. Mr. Adams was the member for Massachu-

setts. This committee finally reported a series of resolves disavowing on the part of the free states any right to interfere with slavery in the slave states; a bill for the admission of New Mexico, leaving it to the inhabitants to allow or exclude slavery as they might decide; and an amendment to the constitution forbidding all interference on the part of congress with slavery in these states. The bill for the admission of New Mexico was rejected, but the other two measures were passed in the house by large majorities. Mr. Adams supported them all, and gave his reasons for so doing in a speech delivered Jan. 31, 1861. In 1861 he was appointed by President Lincoln minister to England, in place of Mr. Dallas. Mr. Adams arrived in London and assumed his duties about the middle of May. These duties were most arduous. With a few exceptions, the feeling alike of the ruling and the commercial classes of England was either unfriendly to us or indifferent. Mr. Adams had to maintain the rights of his country with unbending firmness, and at the same time to keep his spirit under perfect rule, as any explosion of ill temper or any expression of irritation would have been turned to the disadvantage alike of himself and his country. In the many discussions he had with the British ministry he showed a complete knowledge alike of international law and of the history of his own country, as well as discretion, tact, and good temper. His influence as a public man was increased by his social qualities, his agreeable conversation, and his familiarity with the whole range of English literature. When in 1868, after an absence of seven years, he returned home, Mr. Adams left England with the respect of every man who had been brought into official relations with him, and with a large amount of warm personal regard. In December, 1879, he pronounced before the New York historical society a discourse on American neutrality, which has been printed. Upon the ratification by England and America of the treaty of Washington for the settlement of the claims of each country against the other growing out of the civil war, Mr. Adams was selected by the president as the American arbitrator, and upon that duty sailed for Europe in November, 1871.—Mr. Adams has been a contributor to the "North American Review" and the "Christian Examiner," and between 1845 and 1848 was the editor of a political daily paper at Boston, by which he contributed to prepare the way for the present republican party. He is principally known, however, as the editor of his grandfather's collected writings, published in ten volumes, the first volume containing a life of John Adams written by him. The same duty which Mr. Adams has performed for his grandfather, he intends to perform for his father, for the execution of which he possesses abundant and most valuable materials.—John Quincy, eldest son of the preceding, a lawyer and politician, born in

Boston, Sept. 22, 1833. He was fitted for college at the Latin school, and graduated at Harvard college in 1853. In 1855 he was admitted to the bar, and has ever since had a moderate professional practice, principally in Quincy, his place of residence. He was an earnest republican during the civil war, and served on Gov. Andrews's staff. In 1866 he was chosen representative to the legislature from the town of Quincy. In 1867, having avowed his adhesion to the policy of President Johnson, he was nominated for reelection by the democrats and defeated. The same year he was also the democratic candidate for governor of Massachusetts, with the same result. In 1869 he was again chosen to the legislature, and for the third time in 1870. In the autumn of 1871 he was an unsuccessful candidate for the offices of governor and representative. In the course of his public career Mr. Adams has had occasion to make many speeches, which were remarkable for manly independence and vigorous statement. In the Massachusetts house of representatives, as leader of a hopeless minority, he secured in a high degree the respect of his political opponents. — **Charles Francis, Jr.**, brother of the preceding, born in Boston, May 27, 1835, graduated at Harvard college in 1856, studied law, and was admitted to practice in 1858. At the breaking out of the war of secession he obtained a commission in the first regiment of Massachusetts cavalry, and served throughout the war. He was successively promoted to the rank of captain, lieutenant colonel, and colonel, and led his regiment, the fifth Massachusetts cavalry (colored), into Richmond, April 3, 1865, when that city was occupied by the United States troops. In July, 1865, he was mustered out of service with the brevet rank of brigadier general. Upon his return to civil life he became an active contributor to the "North American Review," writing chiefly on topics connected with the development of the railroad system. In 1869 he was appointed a member of the board of railroad commissioners of Massachusetts. In 1871, in connection with his brother, Prof. Henry Brooks Adams, he published a collected volume of writings under the title of "Chapters of Eric, and other Essays." — **Henry Brooks**, brother of the preceding, and third son of Charles Francis Adams, born in Boston, Feb. 16, 1838, graduated at Harvard college in 1858. He resided in London as his father's private secretary during the latter's term of service as minister to England. In 1870 he was appointed assistant professor of history in Harvard college and became editor of the "North American Review."

ADAMS, Edwin, an American actor, born in Medford, Mass., Feb. 3, 1834. Since 1853, when he made his first appearance upon the stage in Boston, he has acted in many parts of the United States, acquiring a considerable reputation both as a light comedian and a personator of serious characters. Dur-

ing the season of 1869-70 he acted in conjunction with Edwin Booth in New York in several of Shakespeare's plays.

ADAMS, Hannah, one of the earliest female writers in America, born at Medfield, near Boston, in 1755, died at Brookline, Mass., Nov. 15, 1832. She showed at an early age a fondness for study, and acquired a knowledge of Greek and Latin from some divinity students boarding with her father. During the revolutionary war she supported herself by making lace, and afterward by teaching. Her "View of Religious Opinions" (1784) and her "History of New England" (1799) were both successful. Her next work was "Evidences of Christianity" (1801). Her writings brought her little pecuniary profit; yet they secured her many friends, among them the Abbé Grégoire, with whom she carried on a correspondence, through which he aided her in preparing her "History of the Jews" (1812). During the closing years of her life she enjoyed an annuity provided by some friends in Boston. She was the first person whose remains were interred in Mt. Auburn cemetery.

ADAMS, John, second president of the United States, born Oct. 19, 1735 (O. S.), in that part of the town of Braintree, Mass., on the S. shore of Boston harbor, and some ten miles distant from Boston, which has since been erected into the town of Quincy, where he died, July 4, 1826. He was great-grandson of Henry Adams, who emigrated from England about 1640, with a family of eight sons, becoming one of the early settlers in Braintree, where he had a grant of 40 acres of land. The father of John Adams, a deacon of the church and selectman, was a farmer of limited means, to which he added the business of shoemaking. He was enabled, however, to give a classical education to his eldest son John, who graduated at Harvard college in 1755, and at once took charge of the grammar school in Worcester, Mass. The war with France for the possession of the western country was then at its height; and in a remarkable letter to a young friend, which contains some curious prognostications as to what would be in a hundred years the relative population and commerce of England and her colonies, young Adams describes himself as having turned politician. His school he found but "a school of affliction," from which he endeavored to gain relief by devoting himself, in addition, to the study of the law. For this purpose he placed himself under the tuition of the only lawyer of whom Worcester, though the shire town of the county, could then boast. He had thought seriously of the clerical profession, but, according to his own expressions in a contemporary letter, "the frightful engines of ecclesiastical councils, of diabolical malice, and Calvinistic good nature," of the operation of which he had been a witness in some church controversies in his native town of Braintree, had "terrified him out of it." Already he

had longings for distinction. Nothing but want of interest and patronage prevented him from enlisting in the army. Could he have obtained a troop of horse, or a company of foot, he would, so one of his published letters declares, infallibly have been a soldier. After two years' study at Worcester he returned to his father's house in Braintree, and in 1758 commenced life in Suffolk county, of which Boston was the shire town. He gradually introduced himself into practice, and in 1764 married Abigail Smith, a daughter of the minister of the neighboring town of Weymouth, and whose connections occupied a social position superior to that of Mr. Adams's own family. What was still more to the purpose, she was a lady of superior abilities and good sense, and admirably adapted to make him happy. Very shortly after his marriage, the attempt at parliamentary taxation diverted him from law to politics. He promoted the call of a town meeting in Braintree, to instruct the representatives of the town on the subject of the stamp act; and the resolutions which he presented at this meeting were not only voted by the town, but attracted great attention throughout the province, and were adopted word for word by more than forty different towns. Yet Adams, as appears by his published diary, was somewhat alarmed at the violence of the mob in destroying the furniture of Oliver, the stamp distributor, and of Governor Hutchinson, and not a little vexed, as well as alarmed, at the interruption to his own business caused by the refusal of the judges to go on without stamps. He was somewhat consoled, however, by an unexpected appointment on the part of the town of Boston to be one of their counsel along with Jeremiah Gridley, the king's attorney and head of the bar, and James Otis, the celebrated orator, to support a memorial addressed to the governor and council that the courts might proceed with business, though no stamps were to be had. It fell to Adams, as junior counsel, to open the case for the petitioners, and he boldly took the ground—in which his two seniors, the one from his position, the other from his committals in his recently published book on the "Rights of the Colonies," were prevented from following him—that the stamp act was absolutely void, parliament having no right to tax the colonies. Nothing, however, came of this application; the governor and council declined to act, on the ground that it belonged to the judges, not to them, to decide. The repeal of the stamp act soon put an end to the suspension of business, which indeed had only extended to the superior court, the inferior courts going on without stamps. It was on this same occasion that Mr. Adams first made his appearance as a writer in the "Boston Gazette." Among other papers of his was a series of four articles, which were republished in a London newspaper, and subsequently in a collection of documents relating to the taxa-

tion controversy, printed together in a volume. The papers as originally published had no title; in the printed volume they were called an "Essay on the Canon and Feudal Law." They began indeed with some reference to these subjects, but might with much more propriety have been entitled an "Essay on the Government and Rights of New England." Mr. Adams's style was formed, as is evident from these pieces, from the moment he began to write. They may be found in his collected works, edited by his grandson. Mr. Adams's law business continued gradually to increase, and in 1768 he removed to Boston. In that and the next year he was one of the committee to draft instructions to the representatives of the town—a duty which the committee intrusted to him, though he refused to attend and speak at town meetings. In 1770 he was chosen a representative to the general court, notwithstanding he had just before accepted a retainer to defend Captain Preston and his soldiers for their share in what was known as the "Boston Massacre"—a defence conducted with success, in spite of the strong prejudices which it had to encounter. Adams's duties as representative interfered greatly with his business as a lawyer, on which he depended for support, and which by this time had grown to be greater than that of any other lawyer in the province. But he entered with his customary energy upon his new office, becoming the chief legal adviser of the patriot party, and now for the first time an active and conspicuous leader among them. Partly perhaps to escape this leadership, and the loss of time, the labor, and responsibilities which it imposed, as well as to regain his health, which began to suffer, Mr. Adams removed his residence back to Braintree, resigning his seat in the legislature, but still retaining his law office in Boston. A comparative lull in politics for two or three years made his presence in the legislature less indispensable, but still as to all the most important matters of controversy with Governor Hutchinson he was consulted and gave his aid. Indeed, it was not long before he again moved back to Boston, though still resolving to avoid politics and to devote himself to his profession. He wrote soon after a series of letters in a newspaper (republished in his collected works, vol. iii.) on the then mooted question of the independence of the judiciary, and the payment by the crown of the salaries of the judges. Soon afterward he was elected by the general court to the provincial council, but was negatived by Governor Hutchinson. The destruction of the tea and the Boston port bill, that followed, soon brought matters to a crisis. These events produced the congress of 1774. Mr. Adams was chosen one of the five delegates from Massachusetts, and his visit to Philadelphia on this business was the first occasion of his going beyond the limits of New England. In the discussions in the committee on the declaration of colonial rights, he took an active part

in favor of resting those rights upon the law of nature as well as the law of England; and after the substance of the resolutions had been agreed upon, he was appointed to put them into shape. In his diary, published in the second volume of his collected works, and his contemporaneous letters written to his wife and published by his grandson, the most trustworthy and graphic descriptions are to be found of the members and doings of that famous but little known body. The session concluded, Mr. Adams left Philadelphia with no expectation, as he said at the time, of ever seeing it again. Immediately on his return to Massachusetts he was chosen by the town of Braintree a member of the provincial congress then in session. That congress had already appointed a committee of safety, vested with general executive powers; had seized the provincial revenues; had appointed general officers, collected military stores, and taken steps toward organizing an army of volunteer minutemen. Governor Gage had issued a proclamation denouncing these proceedings, but no attention was paid to it. Gage had no support except in the five or six regiments which formed the garrison of Boston, a few trembling officials, and a small minority of timid adherents; while the recommendations of the provincial congress had, by the common consent of the people, all the force of law. Shortly after the adjournment of this congress, Adams applied himself to answering through the newspapers a champion of the mother country's claim, who, under the *nom de plume* of "Massachusettensis," had commenced a series of able and effective papers in a Boston journal, and to whom Adams replied under the signature of "Novanglus." These essays appeared weekly during the winter of 1774-'5, but were cut short by the battle of Lexington. An abridgment of them was published in Almon's "Remembrancer" for 1775, under the title of "A History of the Dispute with America," and afterward in a separate pamphlet. They have also been twice reprinted entire in America, and are given in the 4th volume of Adams's collected works. Their value consists in the strong contemporaneous view which they present of the origin of the struggle between the colonies and the mother country, and of the policy of Bernard and Hutchinson as governors of Massachusetts, which did so much to bring that struggle on. Like all Mr. Adams's writings, they are distinguished by a bold tone of investigation, a resort to first principles, and a pointed style; but, like all his other writings, having been produced piecemeal and on the spur of the moment, they lack order, system, polish, and precision. In the midst of the excitement produced by the battle of Lexington—which at once brought up the spirit even of the most hesitating patriots to the fighting pitch, and which was speedily followed by the seizure of the fortresses of Ticonderoga and Crown Point, and by other similar seizures in other

colonies—Adams set out for Philadelphia to attend the continental congress of 1775, of which he had been appointed a member. This second congress, though made up for the most part of the same men, was a wholly different body from its predecessor. That was a mere consulting convention. The new congress speedily assumed, or rather had thrust upon it by the unanimous consent of the patriots, the exercise of a comprehensive authority, in which supreme executive, legislative, and in some cases judicial functions were united. In this busy scene the active and untiring Adams, one of whose distinguishing characteristics was his capacity and fondness for business, found ample employment, while his bold and pugnacious spirit was not a little excited by the hazards and dignity of the great game in which he had come to hold so deep a stake. Adams had made up his mind that any reconciliation with the mother country was hopeless. The majority of congress were not yet of that opinion. Under the lead of John Dickinson, though against the strenuous resistance of Adams and others, that body voted still another and final petition to the king. Adams succeeded, however, in joining with this vote one to put the colonies into a state of defence, though with protestations that the war on their part was defensive only, and without any intention to throw off their allegiance. Not long after, congress was brought up to the point of assuming the responsibility and control of the military operations which New England had commenced by laying siege to Boston, in which town Gage and his troops were shut up, and before which lay encamped an impromptu New England army of 15,000 men, drawn together immediately after the battle of Lexington. Urged by the New England delegates, congress agreed to assume the expense and control of this army. Adams, in his autobiography, claims the honor of having first proposed Washington for the chief command, a concession intended to secure the good will and firm coöperation of Virginia and the southern colonies. Those colonies urged Gen. Lee for the second place in the army, but Adams insisted on giving that to Artemas Ward, then commanding the New England army before Boston. He supported Lee, however, for the third place. Having assumed the direction of this army, provided for its reorganization, and issued bills of credit to support it, congress took a short recess. Adams, returning home, sat in the interval as a member of the Massachusetts council, which, treating the office of governor as vacant, had, under a clause of the provincial charter intended to meet such cases, assumed the executive authority. On returning to Philadelphia in September, Adams found himself in hot water. Two confidential letters of his, written during the previous session, had been intercepted by the British in crossing Hudson river, and had been published in the Boston papers. Not only did these letters

evinced a zeal for decisive measures which made the writer an object of suspicion to the more conservative of his fellow members of congress, but his reference in one of them to "the whims, the caprice, the vanity, the superstition, the irritability" of some of his colleagues, and in particular to John Dickinson as "a certain great fortune but piddling genius," made him personal enemies who never forgave him. But though for the moment an object of distrust to some of his colleagues, this did not save him from hard work. "I am engaged in constant business," so he wrote about this time, "from seven to ten in the morning in committee, from ten to four in congress, and from six to ten again in committee. Our assembly is scarcely numerous enough for the business; everybody is engaged all day in congress, and all the morning and evening in committees." The committee which chiefly engaged Mr. Adams's attention at this time was one on fitting out cruisers, and on naval affairs generally. This committee laid the first foundation of an American navy, a body of rules and regulations for which—the basis of our existing naval code—was drawn up by Adams. Governor Wentworth having fled from New Hampshire, the people of that province applied to congress for advice as to the method of administration they should adopt. Adams seized the opportunity to urge the necessity of advising all the provinces to proceed at once to institute governments of their own. The news which soon arrived of the supercilious treatment of the petition of congress to the king added strength to his views, and the matter being referred to a committee on which Adams was placed, a report in partial conformity to his ideas was made and adopted. Having been offered the post of chief justice of Massachusetts, Adams toward the end of the year returned home to consult on that and other important subjects. He took his seat in the council, of which he had been chosen a member immediately on his arrival, and was consulted by Washington both as to sending Gen. Lee to New York, and as to the expedition against Canada. It was finally arranged that while Adams should accept the appointment of chief justice, he should still remain a delegate in congress, and till more quiet times should be excused from acting as judge. Under this arrangement he returned to Philadelphia early in 1776. He never took his seat as chief justice, but resigned that office the next year.—Advice similar to that to New Hampshire, on the subject of assuming government, as it was called, had been shortly after given upon similar applications to congress from South Carolina and Virginia. Adams was much consulted by members of the southern delegation (as being better versed than themselves in the subject of republicanism, both by study and experience, coming as he did from the most thoroughly republican section of the country) concerning the form of government which they should adopt. Of several letters

which he wrote on this subject, one more elaborate than the others was printed, under the title of "Thoughts on Government applicable to the Present State of the American Colonies." This pamphlet, largely circulated in Virginia, as a preliminary to the adoption of a form of government by that State, was to a certain extent a rejoinder to that part of Paine's famous pamphlet of "Common Sense" which advocated government by a single assembly. It was also intended to controvert the aristocratic views, somewhat prevalent in Virginia, of those who advocated a governor and senate for life. Adams's system of policy embraced the adoption of self-government by each of the colonies, a confederation, and treaties with foreign powers. This system he continued to urge with zeal and increasing success, till finally, on May 13, he carried a resolution through congress, by which so much of his plan was indorsed by that body as related to the assumption of self-government by the several colonies. The first step thus taken, the others soon followed. A resolution that the United States "are and ought to be free and independent," introduced by R. H. Lee, under instructions from the Virginia convention, was very warmly supported by Adams, and carried, seven yeas to six. Three committees, one on a declaration of independence, another on confederation, and a third on foreign relations, were shortly after appointed. Of the first and third of these committees Adams was a member. The declaration of independence was drawn up by Jefferson, but on Adams devolved the task of battling it through congress in a three days' debate, during which it underwent some curtailment. The plan of a treaty reported by the third committee, and adopted by congress, was drawn up by Adams. His views did not extend beyond merely commercial treaties. He was opposed to seeking any political connection with France, or any military or even naval assistance from her or any foreign power. On June 12 congress had established a board of war and ordnance, to consist of five members, with a secretary, clerk, &c.—in fact, a war department. As originally constituted, the members of this board were taken from congress, and John Adams was made its chairman or president. This position, which was one of great labor and responsibility, as the chief burden of the duties fell upon him, he continued to hold for the next eighteen months, with the exception of a necessary absence at the close of the year 1776, to recruit his health. The business of preparing articles of war for the government of the army was deputed to a committee composed of Adams and Jefferson; but Jefferson, according to Adams's account, threw upon him the whole burden, not only of drawing up the articles—which he borrowed mostly from those of Great Britain—but of arguing them through congress, which was no small task. Adams strongly opposed Lord Howe's invitation to a conference, sent to congress after the

battle of Long Island, through his prisoner, Gen. Sullivan. He was, however, appointed one of the committee for that purpose, along with Franklin and Rutledge, and his autobiography contains some curious anecdotes of the visit. Besides his presidency of the board of war, Adams was also chairman of the committee upon which devolved the decision of appeals in admiralty cases from the state courts.— Having thus occupied for nearly two years a position which gained him the reputation among at least a portion of his colleagues of having “the clearest head and firmest heart of any man in congress,” he was appointed near the end of the year 1777 a commissioner to France to supersede Deane, whom congress had determined to recall. He embarked at Boston, in the frigate *Boston*, on Feb. 12, 1778, reached Bordeaux after a stormy passage, and arrived on April 8 at Paris. Already before his arrival the alliance with France had been completed, and his stay was not long. He found that a very great antagonism of views and feeling had arisen between the three commissioners, Franklin, Deane, and Arthur Lee, of whom the embassy to France had been originally composed; and as the recall of Deane had not reconciled the other two, Adams advised, as the only means of giving unity and energy to the mission, that it should be intrusted to a single person. This suggestion was adopted, and in consequence of it, Franklin having been appointed sole ambassador in France, Adams returned home in the same French frigate which took out the new French minister, the chevalier de la Luzerne. He arrived at Boston just as a convention was about to meet to form a state constitution for Massachusetts; and being chosen a delegate from Braintree, he took a leading part in its formation. Before this convention had finished its business, he was appointed by congress minister to treat with Great Britain for peace and commerce, under which appointment he sailed again for France in 1779, in the same French frigate in which he had returned. Very contrary to his own inclinations, Mr. Adams was prevented by Vergennes, the French minister of foreign affairs, from making to Great Britain any communication of his powers. In fact, Vergennes and Adams already were and continued to be to each other objects of serious distrust, in both cases quite unfounded. Vergennes feared lest advances toward treating with England might lead to some sort of reconciliation with her short of the independence of the colonies, which was contrary to his ideas of the interest of France. The communications made to him by Gérard, the first French minister in America, and Adams's connection with the Lees, whom Vergennes suspected, though unjustly, of a secret communication through Arthur Lee with the British ministry, led him to regard Mr. Adams as the representative of a party in congress desirous of such a reconciliation; nor did he rest till he had obtained from

congress, some two years after, the recall of Mr. Adams's powers to negotiate a treaty of commerce, and the conjunction with him of several colleagues to treat for peace, of whom Franklin, who enjoyed his entire confidence, was one. Adams, on the other hand, not entirely free from hereditary English prejudices against the French, vehemently suspected Vergennes of a design to sacrifice the interests of the United States, especially the fisheries and the western lands, to the advancement of the Spanish house of Bourbon. While lingering at Paris, with nothing to do except to nurse these suspicions, Adams busied himself in furnishing communications on American affairs to a semi-official gazette, the *Mercure de France*, conducted by M. Genet, chief secretary in the foreign bureau, and father of the French minister in America, who subsequently rendered that name so notorious. Finding his position at Paris not very comfortable, he proceeded to Holland in July, 1780, his object being to form an opinion as to the probability of borrowing money there. Just about the same time he was appointed by congress to negotiate a Dutch loan, Laurens, who had been selected for that purpose, being not yet ready to leave home. By way of enlightening the Dutch as to American affairs, Adams published in the “*Gazette*” of Leyden, and in a magazine called *Politique hollandaise*, a number of papers and extracts, including several which, through a friend, he procured to be first published in a London journal, to give to them an English character. To these he added a direct publication of his own, afterward many times reprinted, and to be found in the 7th volume of his collected works, under the title of “*Twenty-six Letters upon Interesting Subjects, respecting the Revolution in America.*” He had commenced negotiations for a loan, when his labors in that direction were interrupted by the sudden breach between England and Holland, consequent upon the capture of Laurens, and the discovery of the secret negotiation carried on between him and Van Berkel of Amsterdam, which, though it had been entered upon without authority from the Dutch states, the British made the pretence for a speedy declaration of war. Adams was soon after appointed minister to Holland in place of the captured Laurens, and at the same time was commissioned to sign the articles of armed neutrality, which had just made their appearance on the political scene. Adams presented memorials to the Dutch government, setting forth his powers in both respects; but before he could procure any recognition, he was recalled in July, 1781, to Paris, by a notice that he was needed there in his character of minister, to treat of peace. Adams's suspicions of Vergennes had, meanwhile, been not a little increased by the neglect of France to second his applications to Holland. With Vergennes the great object was peace. The finances of France were sadly embarrassed. Vergennes

wished no further complications to the war, and, provided the English colonies should be definitely separated from the mother country, which he considered indispensable to the interest of France, he was not disposed to insist on anything else. It was for this reason that he had urged upon congress, through the French minister at Philadelphia, and just about this time had succeeded in obtaining from congress—though the information had not yet reached Paris—not only the withdrawal of Adams's commission to treat of commerce, and the enlargement to five of the number of commissioners to treat of peace, but an absolute discretion intrusted to the negotiators as to everything except independence and the additional direction that in the last resort they were to be governed by Vergennes's advice. The cause of sending for Adams, who still occupied, so far as was known at Paris, the position of sole negotiator for peace, was the offer of a mediation on the part of Russia and the German empire. But this offer led to nothing. Great Britain haughtily rejected it on the ground that she would not allow France to stand between her and her colonies.—Returning to Holland, Mr. Adams, though still unsupported by Vergennes, pushed with great energy his reception as ambassador by the states general, which at length, April 19, 1782, he succeeded in accomplishing. Following up this success with his customary perseverance, he succeeded before the end of the year in negotiating a Dutch loan of two millions of dollars, the first of a series which proved a chief financial resource of the continental congress in its later days. He also succeeded in negotiating a treaty of amity and commerce. His success in these negotiations, considering the obstacles he had to encounter, and the want of support from Vergennes, he was accustomed to regard as the greatest triumph of his life.—Before this business was completed, Mr. Adams received urgent calls to come to Paris, where Jay and Franklin, two of the new commissioners, were already treating for peace, and where he arrived Oct. 26. Though Mr. Jay had been put into the diplomatic service by the procurement of the party in congress in the French interest, his diplomatic experience in Spain had led him to entertain doubts also as to the sincere good will of Vergennes. A confidential despatch from M. Marbois, French secretary of legation in America, intercepted by the British, and which Oswald, the British negotiator at Paris, communicated to Franklin and Jay, with a view to make bad feeling between them and the French minister, had, along with other circumstances, induced Franklin and Jay to disregard their instructions, and to proceed to treat with Oswald without communicating that fact to Vergennes, or taking his advice as to the terms of the treaty—a procedure in which Adams, after his arrival, fully concurred. It was chiefly through his energy and persistence that the participation of America

in the fisheries was secured by the treaty, not as a favor or privilege, but as a right—a matter of much greater importance than now, the fisheries being at that time a more important branch than now of American maritime industry.—Immediately upon the signature of the preliminary articles of peace, Adams asked leave to resign all his commissions and to return home, to which congress responded by appointing him a commissioner jointly with Franklin and Jay to negotiate a treaty of commerce with Great Britain. His first visit to England was, however, in a private character, to recruit his health, after a violent fever with which he had been attacked, shortly after signing the treaty of peace. He spent some time first at London, and afterward at Bath; but while still an invalid he was recalled, in the dead of winter, to Holland, which he reached only after a very stormy and uncomfortable passage, there to negotiate a new loan, as the means of meeting government bills drawn in America, which were in danger of protest from want of funds—a business in which he succeeded, though not without paying a pretty high premium. Adams was included, along with Franklin and Jefferson, the latter sent out to take the place of Jay, in a new commission to form treaties with foreign powers; and his being joined by Mrs. Adams and their only daughter and youngest son, his other two sons being already with him, reconciled him to the idea of remaining abroad. With his family about him he fixed his residence at Auteuil, near Paris, where he had an interval of comparative leisure and enjoyment. The chief business of the new commission was the negotiation of a treaty with Prussia, advances toward which had first been made to Adams while at the Hague, negotiating the Dutch loan. But before that treaty was ready for signature, Adams was appointed by congress minister to the court of St. James's, where he arrived in May, 1785. The English government, of which the feelings were well represented by those of the king, had neither the magnanimity nor the policy to treat the new American states with generosity, nor hardly with justice. Adams was received with evility, but no commercial arrangements could be made, and his chief employment was that of complaining of the non-execution of the treaty of peace, especially in relation to the non-surrender of the western posts, and in attempting to meet similar complaints urged not without strong grounds on the part of the British, more particularly as to the obstacles put in the way of the collection of British debts, which were made an excuse for the detention of the western posts. Made sensible in many ways of the aggravation of British feelings toward the new republic, whose condition immediately after the peace was somewhat embarrassing, and not so flattering as it might have been to the advocates and promoters of the revolution,

the situation of Adams was rather mortifying than agreeable. Meanwhile he was obliged to pay a new visit to Holland to negotiate a new loan as a means of paying the interest on the Dutch debt. He was also engaged in a correspondence with his fellow commissioner, Mr. Jefferson, then at Paris, on the subject of a treaty with the Barbary powers and the return of the Americans held captive by them. But his most engrossing occupation at this time was the preparation of his "Defence of the American Constitutions," of which the object was the justification of balanced governments and a division of powers, especially the legislative, against the idea of a single assembly and a pure democracy, which had begun to find many ardent advocates, especially on the continent. The greater part, however, of this book—the most voluminous of his publications—consists of summaries of the histories of the Italian republics, by no means essential to the argument, and rather an exerescence. Though it afterward subjected the author to charges of monarchial and anti-republican tendencies, this book was not without its influence on the adoption of the federal constitution, during the discussion upon which the first volume of it appeared.—Great Britain not having reciprocated the compliment by appointing a minister to the United States, and there being no prospect of his being able to accomplish any of the objects of his mission, Adams had solicited a recall, which was sent out to him in February, 1788, accompanied by a resolution of congress conveying the thanks of that body for "the patriotism, perseverance, integrity, and diligence" which he had displayed in his ten years' service abroad. Immediately on his arrival home, Mr. Adams was reappointed a delegate from Massachusetts to the continental congress; but he never resumed his seat in that body, which was now just about to expire.—When the new government came to be organized under the newly adopted federal constitution, as all were agreed to make Washington president, attention was turned to New England for a vice president. This office was then regarded as of much higher consequence than now. In fact, as the constitution originally stood, the candidates for the presidency and vice presidency were voted for without any distinct specification, the second office falling to the person who had the second highest vote. Out of 69 electors, John Adams had the votes of 34; and this being the second highest number, he was declared vice president. The other 35 votes were scattered upon no less than 10 candidates. By virtue of his new office he became president of the senate, a position not very agreeable to his active and leading temperament, better fitted for debate, but one in which the close division in the senate, resulting often in a tie between the supporters and the opponents of the new system, gave him many times a controlling voice. In the first congress he gave no few-

er than 20 casting votes, always upon important organic laws, and always in support of Washington's policy.—Down to this period Adams had sympathized in political feeling and sentiment with Jefferson, with whom he had served both in the continental congress and abroad. On the question of the French revolution, which now burst upon the world, a difference of opinion arose between them. From the very beginning Adams, then almost alone, had argued no good from that movement. As the revolution went on and began to break out in excesses, others began to be of this opinion. Adams then gave public expression to some of his ideas on that subject in a series of "Discourses on Davila," furnished to a Philadelphia newspaper and afterward collected into a volume. Taking the history of nations, particularly Davila's account of the French civil wars, and the general aspects of human society as his text, Adams pointed out as the great springs of human activity, at least in all that related to politics, the love of superiority, the desire of distinction, admiration, and applause; nor in his opinion could any government be permanent or secure which did not provide as well for the reasonable gratification as for the due restraint of this powerful passion. Repudiating that democracy pure and simple then coming into vogue, and of which Jefferson was the advocate, he insisted that a certain mixture of aristocracy and monarchy was necessary to that balance of interests and sentiments without which, as he maintained, free governments could not exist. This work, which reproduced more at length and in a more obnoxious form the fundamental ideas of his "Defence of the American Constitutions," made Adams a great bugbear to the ultra-democratic supporters of the principles and policy of the French revolutionists; and at the second presidential election in 1792, they set up as a candidate against him George Clinton of New York. But Mr. Adams was reelected by a decided vote. The wise policy of neutrality adopted by Washington received the hearty concurrence of Adams. While Jefferson left the cabinet to become in nominal retirement the leader of the opposition, Adams continued as vice president to give Washington's administration the benefit of his casting vote. It was only by this means that a neutrality act was carried through the senate, and that the progress was stopped of certain resolutions which had previously passed in the house of representatives, embodying restrictive measures against Great Britain, intended or at least calculated to counterwork the mission to England on which Mr. Jay had already been sent.—Washington being firmly resolved to retire at the close of his second presidential term, the question of the succession now presented itself. Jefferson was the leader of the opposition, who called themselves republicans, the name democrat being yet in bad

odor, and, though often imposed as a term of reproach, not yet voluntarily assumed except by a few more ultra partisans. Hamilton was the leader of the federal party, as the supporters of Washington's administration had christened themselves. But though Hamilton's zeal and energy had made him, even while like Jefferson in nominal retirement, the leader of the federalists, he could hardly be said to hold the same place with them that Jefferson did with the republicans, whose presidential candidate he was, a position among the federalists which belonged less to Hamilton than to Adams or Jay, whose greater age and longer public service placed them more conspicuously in the public eye. Hamilton, though he had always spoken of Adams as a man of unconquerable intrepidity and incorruptible integrity, and as such had already twice supported him for vice president, would yet have much preferred Jay. The position of Adams was, however, such as to render his election more probable than that of Jay, and to determine his selection as the candidate of the federalists. Jay, by his negotiation of the famous treaty which bore his name, had for the moment drawn down upon himself a strong feeling of hostility on the part of its numerous and bitter opponents. Adams stood, moreover, as vice president in the line of promotion, and was more sure of the New England vote, which was absolutely indispensable to the success of either. One of the candidates being taken from the North, it seemed politic to select the other from the South, and the federalist leaders pitched for that purpose upon Thomas Pinckney of South Carolina. Indeed, there were some, and Hamilton was among the number, who secretly wished that Pinckney might receive the larger vote, and so be chosen president over Adams's head—a result, from the likelihood of Pinckney's obtaining more votes than Adams at the South (as he really did), almost sure to happen could the northern federal electors be persuaded to vote equally for Adams and for Pinckney, which Hamilton labored to effect. The fear, however, that Pinckney might be chosen over Adams, led to the withholding from Pinckney of eighteen New England votes, so that the result was not only to make Jefferson vice president, as having more votes than Pinckney, but also to excite prejudices and suspicions in the mind of Adams against Hamilton, which, being reciprocated by him, led speedily to the disruption and final overthrow of the federal party. It had almost happened, such was the equal division of parties, that Jefferson had this time been chosen president, the election of Adams, who had 71 votes to Jefferson's 69, being only secured by two stray votes cast for him, one in Virginia and the other in North Carolina, tributes of revolutionary reminiscences and personal esteem. Chosen by this slender majority, Mr. Adams succeeded to office (March 4,

1797) at a very dangerous and exciting crisis of affairs. The progress of the French revolution had superinduced upon previous party divisions a new and very vehement one. Jefferson's supporters, who sympathized very warmly with the French republic, gave their moral if not their positive support to the claim set up by its rulers, but which Washington had refused to admit, that under the provisions of the French treaty of alliance the United States were bound to support France against Great Britain, at least in the defence of her West India possessions. The other party, the supporters of Adams, upheld the policy of neutrality adopted by Washington. At the same time that Washington had sent Jay to England to arrange, if possible, the pending difficulties with that country, wishing also to keep on good terms with the French republic, he had recalled Gouverneur Morris, who as minister to France had made himself obnoxious to the now predominant party there, and had appointed James Monroe in his place. Monroe, instead of conforming to his instructions and attempting to reconcile the French to Jay's mission, had given them assurances on the subject quite in contradiction with the treaty as made, both the formation and ratification of which Monroe had done his best to defeat. He had in consequence been recalled by Washington shortly before the close of his term of office, and C. C. Pinckney, a brother of Thomas Pinckney, had been appointed in his place. The French authorities, offended at this change and at the ratification of Jay's treaty in spite of their remonstrances, while they dismissed Monroe with great ovations, refused to receive the new ambassador sent in his place, at the same time issuing decrees and orders highly injurious to American commerce. Almost the first act of Mr. Adams as president was to call an extra session of congress to consider what should be done. Not only was a war with France greatly to be dreaded and deprecated on account of her great military and naval power, but still more so on account of the very formidable party which, among the ultra republicans, she could muster within the states themselves. Under these circumstances, the measure resolved upon by Adams and his cabinet was the appointment of a new and more solemn commission to France, composed of Pinckney and two colleagues, for which purpose the president selected John Marshall of Virginia and Elbridge Gerry of Massachusetts. But instead of receiving and openly treating with those commissioners, Talleyrand, lately an exile in America, but now secretary of foreign affairs to the French directory, entered into an intrigue with them through several unaccredited and unofficial agents, of which the object was to induce them to promise a round bribe to the directors and a large sum of money to the exhausted French treasury, by way of purchasing forbearance. As Pinckney and Marshall appeared less pliable than Gerry,

Talleyrand finally obliged them to leave, after which he attempted, though still without success, to extract money or promises of it from Gerry alone. The publication of the despatches in which these discreditable intrigues were disclosed (an event on which Talleyrand had not calculated) produced a great excitement both in Europe and America. Talleyrand attempted to escape by disavowing his agents, and pretending that the American ministers had been imposed upon by adventurers. Gerry left France, and the violation of American commercial and maritime rights was pushed to new extremes. In America the effect of all this was greatly to strengthen for the moment the federal party. The grand jury of the federal circuit court for Pennsylvania set the example of an address to the president, applauding his manly stand for the rights and dignity of the nation. Philadelphia, which, under the lead of Millin, McKean, and others, had gone over to the opposition, was suddenly converted once more, as during Washington's first term, to the support of the federal government. That city was then the headquarters of the American newspaper press. All the hitherto neutral papers published there, as well as several others which had more or less decidedly leaned to the opposition, came out now in behalf of Adams. Besides an address from five thousand citizens, the young men got up a separate address of their own. This example was speedily imitated all over the country, and the spirited replies of the president, who was now in his element, served in their turn to blow up and sustain the blaze of patriotic indignation. These addresses, circulated everywhere in the newspapers, were collected at the time in a volume, and they reappear in Adams's works, of which they form a characteristic portion. A navy was set on foot, the old continental navy having become extinct, and an army was voted and partly levied, of which Washington accepted the chief command. Merchant ships were authorized to protect themselves. The treaty with France was declared to be at an end, and a quasi war with France ensued. It was not, however, the policy of France to drive the United States into the arms of Great Britain. Even before Gerry's departure Talleyrand had made some advances toward reconciliation, which were afterward renewed by communications opened with Vans Murray, the American minister to Holland. The effect of the French outrages and of the progress of the French revolution had been to create, in a part at least of the federal party, the desire for an absolute breach with France—a desire felt by Hamilton, and by three at least out of the four cabinet officers whom Adams had found and had kept in office. In his message to congress announcing the expulsion of Pinckney and Marshall, Adams had declared "that he would never send another minister to France without assurances that he would be received." This

was on the 21st of July, 1798. When, therefore, on the 18th of February following, without consulting his cabinet or giving them any intimation of his intentions, he sent into the senate the nomination of Vans Murray as minister to France, this act took the country by surprise, and hastened the downfall of the federal party. Some previous acts of Adams, such as the appointment of Gerry, which his cabinet officers had striven to prevent, and his disinclination to make Hamilton second in command of the army till forced into it by Washington, had strengthened the distrust entertained of Adams by Hamilton and many of his friends; and Adams was now accused of seeking, in his attempt to reopen diplomatic intercourse with France, to reconcile his political opponents of the republican party, and to secure by unworthy and impolitic concessions his own reelection as president. The opposition to Murray's nomination so far prevailed that Murray received two colleagues, Ellsworth of Connecticut and Davie of North Carolina; but the president would not authorize the departure of Ellsworth and Davie till he had received explicit assurances from Talleyrand that they would be duly received as ministers. On arriving in France they found the directory superseded and Napoleon Bonaparte first consul, with whom they managed to arrange the matters in dispute. But, however beneficial to the country, this mission proved very disastrous to Adams personally, and to the political party to which he belonged. He justified its appointment on the ground of assurances conveyed to him through a variety of channels that France desired peace, and he excused himself for not having consulted his cabinet by the fact that he knew what their opinion was without asking them—decidedly hostile, that is, to any such attempt as he had determined to make. The masses of the federalists, fully confident of Adams's patriotism, were well enough disposed to acquiesce in his judgment; but many of the leaders were implacable. The quarrel was further aggravated by Adams's dismissal at this time of his cabinet officers and the construction of a new cabinet. The pardon of Fries, convicted of treason for armed resistance in Pennsylvania to the levy of certain direct taxes, was also regarded by many at the time as a piece of misplaced lenity on the part of Adams, dictated, it was said, by a mean desire of popularity in a case in which severe example was needed. But Adams will hardly suffer with posterity from his unwillingness to be the first president to sign a death warrant for treason, especially as there was room for grave doubts whether the doings of this person amounted to treason as defined by the constitution of the United States.—In this divided condition of the federal party the presidential election came on. Adams was still too popular with the mass of the party to encourage any attempt to drop him altogether, and the malcontents were reduced to the old expedient of attempting by secret

understanding and arrangement to reduce his vote in the electoral college below that of C. C. Pinckney, the other of the two candidates voted for by the federalists. The republicans, on the other hand, under the prospect of an arrangement with France, rapidly recovered from the blow inflicted upon them by the violence and mercenary rapacity lately charged upon their French friends, but which they now insisted was a charge without foundation. Taking advantage of the dissatisfaction at the heavy taxes necessarily imposed to meet the expenses of warlike preparations, and especially of the unpopularity of the alien law and the sedition law—two acts of congress to which the prospect of war had led—they pushed the canvass with great energy; while in Thomas Jefferson and Aaron Burr they had two leaders unsurpassed for skill in party tactics, and in Burr, at least, one little scrupulous as to the means which he employed. Not only was the whole blame of the alien and sedition acts, to which he had merely assented without ever having recommended them, laid on Adams's shoulders, but he was the object of most vehement and bitter attacks for having surrendered up, under one of the provisions of Jay's treaty, one Thomas Nash, an English sailor, charged with mutiny and murder. Having been recognized and arrested in Charleston, S. C., Nash had endeavored to save himself by assuming the name and character of Jonathan Robbins, an American citizen, in the light of which assumed character the greater part of Adams's political opponents insisted upon exclusively regarding him, and Adams himself as having basely yielded up an American citizen, who, it was argued, even if guilty of mutiny as charged, had been justified in it by the fact of having been, as it was alleged, previously pressed into the British naval service. Nor was it against his public acts alone, nor even to his political opponents, that these assaults upon Mr. Adams were confined. With strong feeling and busy imagination, loving both to talk and write, Adams had been betrayed into many confidences and into free expression of feelings, opinions, and even conjectures and suspicions—a weakness very unsuited to the character of a politician, and which he had frequent occasion to rue. During Washington's first term of office he had thus been led into a confidential correspondence with Tench Coxe, who held at that time the place of assistant secretary of the treasury, and had afterward been appointed supervisor of the internal revenue, but who since Adams's accession had been dismissed from this place on the charge of being a spy upon the treasury department in the service of the "Aurora," the principal newspaper organ of the opposition, with which party Coxe sympathized, and since his recent dismissal from office had acted. In this state of mind Coxe betrayed a private confidential letter of Adams, which, after having been handed about in manuscript for some time, to the great damage of

Adams with his own party, was finally printed in the "Aurora," of which Coxe had become one of the principal contributors. The purport of this letter, written as long ago as May, 1792, was to give countenance to the favorite charge of the opposition that Washington's cabinet, and of course Adams's, which followed the same policy, was under British influence, and that Thomas Pinckney and his brother C. C. Pinckney, candidates with Adams on the federal presidential ticket, were especially obnoxious to this suspicion. The publication of this letter was followed up by a still more deadly blow in the shape of a pamphlet written and printed and signed by Hamilton, and probably intended by him for private distribution among the federal leaders, but which was made public by Aaron Burr, who had succeeded in possessing himself of some of the proof sheets. This pamphlet had its origin in the same charge against Hamilton of being under British influence, thrown out by Adams in private conversation, and as to which, when written to by Hamilton, he had refused to give any explanation, though when a similar request was made by C. C. Pinckney in consequence of the publication of the letter to Coxe, Adams fully exonerated both him and his brother in a published letter from any suspicion which his letter to Coxe might seem calculated to convey. Hamilton declared in the conclusion of his pamphlet, that as things then stood he did not recommend the withholding from Adams of a single vote. Yet it was the leading object of his pamphlet to show, without denying Adams's patriotism and integrity, or even his talents, that he had great and intrinsic defects of character which disqualified him for the place of chief magistrate, and the effect which he desired it to have must have been to give C. C. Pinckney the presidency, by causing a certain number of votes to be withheld from Adams. The result, however, of the election was to throw out both the federal candidates. Adams received 65 votes and Pinckney 64, while Jefferson and Burr had 73 each. In the ensuing struggle between Jefferson and Burr Adams took no part.—Immediately on the expiration of his term of office (1801) he left Washington, to which shortly before the seat of government had been removed, without even stopping to be present at the inauguration of Jefferson, against whom he felt a sense of personal wrong, probably thinking he had been deluded by false professions as to Jefferson's views on the presidential chair. This state of feeling on the part of Adams led to a strict non-intercourse for the next 13 years, though both were much given to letter-writing, and had previously, at least till within a short time before, been on terms of friendly correspondence. The only acknowledgment for his 25 years' services to the nation which Mr. Adams carried with him in this unwelcome and mortifying retirement, was the privilege which had been granted to Washington on his withdrawal from the presidency, and after his death to his widow,

and bestowed likewise upon all subsequent ex-presidents and their widows, of receiving his letters free of postage for the remainder of his life. Fortunately for Adams, his thrifty habits and love of independence, sustained during his absence from home by the economical and managing talents of his wife, had enabled him to add to the savings from his profession before entering public life, savings from his salaries enough to make up a sufficient property to support him for the rest of his life in a style of decent propriety and solid comfort, in conformity to his ideas. Almost all his savings he had invested in the farming lands about him. In his vocabulary, property meant land. With all the rapid wealth then being acquired by trade and navigation, he had no confidence in the permanency of any property but land, views in which he was confirmed by the commercial revulsions of which he lived to be a witness. He was the possessor, partly by inheritance and partly by purchase, of his father's farm, including the house in which he was himself born; but he had transferred his own residence to a larger and handsomer dwelling near by, forfeited by one of the refugee Tories of the revolution, and of which he had become the purchaser, where he spent the next quarter of a century. In this comfortable home, acquired by himself, he sought consolation for his troubled spirit in the cultivation of his lands, in books, and in the bosom of his family. Mrs. Adams, to her capacities as a housekeeper, steward, and farm manager, added a brightness and activity of mind and a range of reading, such as fully qualified her to sympathize with her husband in his public as well as his private career. She shared his taste for books, and, as his published letters to her are unsurpassed by any American letters ever yet printed, so hers to him as well as to others, from which a selection has also been published, show her, though with less of nature and more of formality than his letters exhibit, yet worthy of the admiration and respect as well as of the tenderness with which he always regarded her. To affections strong enough to respond to his, a sympathy equal to his highest aspirations, a proud feeling of superiority and an enjoyment of it equal to his own, she added what is not always found in such company, a flexibility sufficient to yield to his stronger will, without disturbance to her serenity or his, and without the least compromise of her own dignity or her husband's respect and deference for her. While she was not ignorant of the foibles of his character, and knew how to avail herself of them when a good purpose was to be served by it, yet her admiration of his abilities, her reliance upon his judgment, her confidence in his goodness, and her pride in his achievements, made her always ready to yield and to conform. His happiness and honor were always her leading object. This union was blessed with children well calculated to add to its happiness. Mr.

Adams indeed had the misfortune to lose by death, just at the moment of his retirement from office, private grief being thus added to political disappointment, his second son, Charles. He had grown to manhood, had been married and had settled in New York with flattering prospects, but had died under painful circumstances, which his father speaks of in a contemporary letter as the deepest affliction of his life, leaving a wife and two infant children dependent on him. Col. Smith, an officer of the revolution, who had been Adams's secretary of legation at London, and who had married his only daughter, did not prove in all respects such a son-in-law as he could have wished. His pecuniary affairs becoming embarrassed, his father-in-law had provided for him by several public appointments, the last of which was that of surveyor of the port of New York, which position he was allowed to hold till 1807, when he was removed from it in consequence of his implication in Miranda's expedition. Nor did Thomas Boylston Adams, the third son, though a person of accomplishments and talents, fully answer the hopes of his parents. But all these disappointments were more than made good by the oldest son, John Quincy Adams, who subsequently to his recall from the diplomatic service abroad, into which Washington had introduced him, and in which his father (urged to it by a letter from Washington) had promoted him, was chosen one of the senators in congress from Massachusetts.—All consolations, domestic or otherwise, at Mr. Adams's command, were fully needed. Never did a statesman sink more suddenly, at a time too when his powers of action and inclination for it seemed wholly unimpaired, from a leading position to more absolute political insignificance. His grandson tells us that while the letters addressed to him in the year prior to March 1, 1801, may be counted by thousands, those of the next year scarcely number a hundred, while he wrote even fewer than he received. Nor was mere neglect the worst of it. He sank, loaded with the jibes, the sneers, the execrations even of both political parties into which the nation was divided. It is easy to see now that hardly any degree of union or skill on the part of the federalists, a minority from the beginning and only sustained from the first by the name of Washington and the talent and activity of the inferior leaders, could have prevented the ultimate triumph of the other party. But, as is usual with contemporaries, the disposition then was to explain everything by the skill or luck of individual movements, and a large portion of the most active leaders of the federal party were inclined to hold Adams personally answerable both for the breach in their ranks and for their subsequent overthrow. At the same time, the other party, identifying him with all the measures most obnoxious to them, especially the alien and sedition laws, long continued to use his name as a sort of synonyme for aristocracy,

longing after monarchy, bigotry, tyranny, and oppression in general. Especially were they enraged at the passage by the last congress, just before the close of his and their term of office, of a new judiciary act, or rather at Adams's presuming to fill up with federalists the twenty-three new judicial offices, besides attorneys, marshals, and clerks, created by this act. These nominations, stigmatized as "midnight appointments," were assailed, as well as he who made them, by every term of party reproach; nor did the now triumphant republicans rest until, unable to reach these appointees in any other way, they had stripped them of their offices by repealing the act. Though Adams was far more of a speculative philosopher than any of his contemporaries in the field of American politics, except Jefferson, he was by no means philosopher enough to submit with patience to the obloquy with which he was now visited. In the agony of his heart he sat down to defend himself with his pen, at least before the tribunal of posterity. He had been in the habit of keeping, during intervals of his life, a diary or journal, large and very valuable extracts from which appear in the 2d and 3d volumes of his collected works. He now set himself to writing an "Autobiography" and a reply to Hamilton's pamphlet. But though he wrote with great facility and force, neither his eyes, which were weak, his hand, which trembled so as to make the mechanical labor of writing disagreeable, nor yet his habits or his temperament, were favorable to the labor of correction, condensation, and arrangement; and he presently abandoned both those works, though some selections from the "Autobiography" have been published by his grandson by way of filling gaps in his diary. Eight years later, when time had somewhat healed over these wounds, they broke out with new malignancy by reason of renewed attacks upon him by the federalists on account of his son John Quincy Adams having abandoned the federal party, and the disposition evinced by the father to sustain the policy of the administration, rather than that of the federalists, in the disputes which finally terminated in war with Great Britain. Hitherto the Jeffersonian or democratic party had possessed in Boston as its sole newspaper organ "The Chronicle," a very violent paper, of which the staple in times past had been abuse of John Adams as an aristocrat and a monarchist, and the author of the alien and sedition laws. To represent and express the sentiments of a new cohort, which with the years 1806 and 1807 came in Massachusetts to the support of Jefferson, under the leadership of John Q. Adams, a new paper was established called the "Boston Patriot," to which both John Q. Adams and his father became contributors. In the earliest numbers of this paper, John Adams printed (and it may be found in the 9th volume of his collected works) "The inadmissible Principles of the King of England's Proclamation of Oct.

16, 1807, considered," being an examination and refutation of the English doctrine of impressment as applied to British subjects. Very soon, however, he dropped these topics of the day, and reverted to the past. The old charge having been anew brought up against him by some of the federalist papers, of personal motives in setting on foot the mission to France in 1799, he took up that subject in a series of letters to the "Patriot"—also printed in his collected works, vol. ix.—into which he incorporated much of the material collected for his answer to Hamilton. These letters are a valuable contribution to the history of that interesting period, and can hardly fail to be regarded as a complete vindication of Adams's policy and conduct on that occasion—at least if we allow that the immediate welfare of the nation was to be consulted, rather than any supposed prospective interest of any political party. From this beginning Mr. Adams went on to a history especially of his diplomatic career, into which he introduced many valuable documents in his possession. These publications, interrupted and again commenced from time to time, extended over a space of three years. A portion, embracing perhaps two thirds of the whole, was collected and published in pamphlets, which, bound together, made an octavo volume, entitled "Correspondence of the late President Adams, originally published in the Boston 'Patriot' in a series of letters." Thus disjointed, and written, as parts of it evince, and as his published correspondence of this period more clearly shows, under great exasperation of feeling, and coming forth, too, at a period when the events of the day engrossed all thoughts, and during which the history of the revolution was less generally known and less a subject of public interest than at any time before or since, these letters failed to attract the public attention or to satisfy Mr. Adams's ideal of an historical vindication of himself. Seeing how, amid the ignorance and carelessness of the times, the true history of the revolution was in danger of total oblivion or of being transformed into a sort of legend, he abandoned his task with expressions to his private correspondents of contempt for history, and of utter despair of ever having justice done to him. But with the establishment of peace in Europe, and the apparent fulfilment, at least for the moment, of all Mr. Adams's prophecies as to the result of the French revolution, the bitter political obloquy of which he had been the mark—an obloquy directed against him from two opposite quarters at once—began sensibly to relax; and as those who had been contemporaries with his active life one after another dropped off, he himself began to fill, while yet alive, the position in general estimation of a hero of the past. After Mr. Jefferson's withdrawal from political life, through the agency of Dr. Rush, who had all along remained the personal friend of both, correspondence by letter was renewed between Adams

and Jefferson and kept up for the remainder of their lives. About the same time also Adams opened a correspondence with McKean, his friend and coöperator in revolutionary times, but separated from him in the whirlpool of subsequent politics; and he thus drew out from McKean some valuable historical reminiscences. Mr. Adams indeed gave great attention to the subject of American history. His letters to Mr. Tudor (which led to the publication by that gentleman of the "Life of James Otis") shed great light upon the early history of the revolution in Massachusetts. They contributed not a little to give the first impulse to that study of American history, revolutionary and colonial, which, commencing about that time, has rescued those subjects from the hands of rhetoricians and fabulists, and has produced so many valuable and authentic historical works. In his correspondence, which appears to have gradually increased and extended itself, Mr. Adams loved to recall and to reëxplain his theoretical ideas of government, on some points of which he pushed Jefferson rather hard, and which the result of the French revolution so far as then developed seemed to confirm. Another subject in which he continued to feel a great interest was that of theology. He had begun as an Arminian, and the more he had read and thought and the older he grew, the freer views he took. Though clinging with tenacity to the religious institutions of New England, it would seem from his correspondence that he had finally curtailed his theology to the ten commandments and the sermon on the mount. Of his views on this point he gave evidence in his last public act, to which we now approach. Mrs. Adams had died in 1818, but even that shock, severe as it was, did not unsettle the firm grasp of her husband on life, its enjoyments and its duties. When, in consequence of the erection of the district of Maine into a separate state, a convention was to meet in 1820 to revise the constitution of Massachusetts, in the framing of which Mr. Adams had taken so leading a part, though in his 86th year, he was chosen a delegate by his townsmen. Upon his first appearance, with a form yet erect, though tremulous with age, in this convention, which included almost everybody in the state of distinguished intelligence or reputation, Mr. Adams was received by the members standing, and with every demonstration of affection and regard; and a series of resolutions was forthwith offered and passed, containing an enumeration and warm acknowledgment of some of his principal public services, and calling upon him to preside. But this, while duly acknowledging the compliment, he declined on the score of his age and infirmities. The same cause also prevented his taking any very active part in the proceedings. Yet he labored to produce a modification of the third article of the bill of rights, on the subject of public worship and its support, an

article which, when originally drawing the rest of that instrument, he had passed over to other hands. But the time had not yet come for such changes as he wished. The old puritan feeling was still in too great force to acknowledge the equal rights, political and religious, of others than Christians. Yet, however it might be with his colleagues or his fellow citizens, Mr. Adams in this movement expressed his own ideas. One of his latest letters, written in 1825 and addressed to Jefferson, is a remarkable protest against the blasphemy laws, so called, of Massachusetts and the rest of the Union, as being utterly inconsistent with the rights of free inquiry and private judgment.—It is in the letters of Mr. Adams, of which but a small part have yet been published, that his genius as a writer and thinker, and no less distinctly his character as a man, most clearly appear. Down even to the last year of his protracted life, his letters exhibit a wonderful degree of vitality, energy, acuteness, wit, playfulness, and command of language. As a writer of English, little as he ever troubled himself with revision and correction, and we may add as a speculative philosopher, he must be placed first among Americans of all the several generations to which he belonged, except only Franklin; and if Franklin excelled him in humor and geniality, he far surpassed Franklin in compass, wit, and vivacity. Indeed, it is only by the recent partial publication of his letters that his gifts in this respect are beginning to become known. The first collection of his private letters, published in his lifetime and much against his will, though not deficient in the characteristics above pointed out, yet, having been written under feelings of great aggravation and in a spirit of extreme bitterness toward his political opponents, was rather damaging to him. This publication was one of the incidents of his becoming for a third time, in his extreme age, an object of hostility, confined now, however, to a few of the more tenacious of his old federalist opponents, in consequence of the coalition of all parties in New England to support his son, J. Q. Adams, for the presidency. In the interval from 1804 to 1812, Mr. Cunningham, a maternal relative, had drawn him into a confidential correspondence, in which, still smarting under a sense of injury, he had expressed himself with perfect unreserve and entire freedom as to the chief events of his presidential administration and the character and motives of the parties concerned in them. By a gross breach of confidence, of which, like other impulsive and confiding persons, Mr. Adams had been often the victim, those letters were sold by Cunningham's heir in 1824, while the writer and many of the parties referred to were still alive, and were published as a part of the electioneering machinery against J. Q. Adams. They called out a violent retort from Col. Pickering, who had been secretary of state to

Washington and Adams, till dismissed from office by the latter; but though Mr. Jefferson was also severely handled in them, they occasioned no new interruption to the friendly correspondence for some years reëstablished between him and Adams. Those two leading actors in American politics, at first so coöperative and afterward so hostile, again reunited in friendly intercourse, having outlived almost all their fellow actors, continued to descend hand in hand to the grave. Adams lived to see his son president and to receive Jefferson's congratulations upon it. By a remarkable coincidence, they both expired on the 50th anniversary of that declaration of independence in which they had both taken so active a part, Adams, however, being the survivor by a few hours.—Of Adams's personal appearance and domestic character in his old age, his grandson gives the following account: "In figure John Adams was not tall, scarcely exceeding middle height, but of a stout, well knit frame, denoting vigor and long life, yet as he grew old inclining more and more to corpulence. His head was large and round, with a wide forehead and expanded brows. His eye was mild and benignant, perhaps even humorous when he was free from emotion, but when excited it fully expressed the vehemence of the spirit that stirred within. His presence was grave and imposing on serious occasions, but not unbending. He delighted in social conversation, in which he was sometimes tempted to what he called rhodomontade. But he seldom fatigued those who heard him; for he mixed so much of natural vigor of fancy and illustration with the store of his acquired knowledge, as to keep alive their interest for a long time. His affections were warm, though not habitually demonstrated toward his relatives. His anger, when thoroughly aroused, was for a time extremely violent, but when it subsided it left no trace of malevolence behind. Nobody could see him intimately without admiring the simplicity and truth which shone in his actions, and standing in some awe of the power and energy of his will. It was in these moments that he impressed those around him with a sense of his greatness. Even the men employed on his farm were in the habit of citing instances, some of which have been remembered down to the present day. At times his vehemence would become so great as to make him overbearing and unjust. This was most apt to happen in cases of pretension and any kind of wrong-doing. Mr. Adams was very impatient of cant, or of opposition to any of his deeply established convictions. Neither was his indignation at all graduated to the character of the individuals who might happen to excite it. It had little respect of persons, and would hold an illiterate man or a raw boy to as heavy a responsibility for uttering a crude heresy as the strongest thinker or the most profound scholar." The same writer

makes the following remarks on his general character: "His nature was too susceptible to emotions of sympathy and kindness, for it tempted him to trust more than was prudent in the professions of some who proved unworthy of his confidence. Ambitious in one sense he certainly was, but it was not the mere aspiration for place or power. It was a desire to excel in the minds of men by the development of high qualities, the love, in short, of an honorable fame, that stirred him to exult in the rewards of popular favor. Yet this passion never tempted him to change a course of action or to suppress a serious conviction, to bend to a prevailing error or to disavow one odious truth." This last assertion involves some controverted points of history; yet this at least must be granted, that it may be made with far more plausibility of Mr. Adams than of the greater portion of political men. The pecuniary independence which previous to his retirement Mr. Adams had secured by a judicious adaptation of his expenditures to his income, more fortunate than Mr. Jefferson, he maintained till the end of his life. Although he had a large family, including grandchildren and great-grandchildren, dependent upon him, he yet died in the possession of a valuable landed estate.—See "Life and Works of John Adams," by Charles Francis Adams (10 vols. 8vo, Boston, 1850-'56), and "Life of John Adams," by J. Q. and C. F. Adams (2 vols. 8vo, 1871).

ADAMS, John, the assumed name of **ALEXANDER SMITH**, one of the mutineers of the British ship *Bounty*, born in London in 1764, died on Pitcairn island, March 29, 1829. In 1787 he joined the *Bounty* as a common sailor, and was one of those who revolted against Lieut. Bligh on April 28, 1789. (See **BLIGH, WILLIAM**.) On Jan. 23, 1790, after various adventures, Adams landed with the other mutineers and a number of Tahitian men and women on Pitcairn island, where he spent the rest of his life. In 1800 he found himself the sole surviving Englishman, and the only guardian and teacher of a community of women and children. He organized divine service according to the forms of the church of England, and acted also as a schoolmaster. In 1808, when Capt. Mayhew Folger, of the American ship *Topaz*, landed on the island, Adams gave him an account of the feuds among his companions and the Tahitian men and women, ending in the violent death of all except himself and Young. Capt. Folger, in return, gave him a rapid sketch of the great events of the preceding 20 years, all of which were entirely new to him. The captain's report of this extraordinary meeting with Adams bore testimony to the excellent moral and religious training of the little community, and was accompanied by the chronometer and azimuth compass of the *Bounty*, presented to him by Adams. It was after the visit of Capt. Folger that he changed his real name of

Alexander Smith to John Adams, to avoid recognition and conviction for mutiny in England. The island was visited only two or three times afterward during Adams's life. In 1825 a man named Buffett was permitted to settle there, and, being well educated, relieved Adams of the business of teaching. Lady Belcher, in her work on the "Mutineers of the Bounty" (London, 1871), says: "By the mercy of God and by the aid of his Bible and prayer book, which he had so earnestly studied, John Adams succeeded in establishing such a community as has been the dream of poets and the aspiration of philosophers." (See PITCAIRN ISLAND.)

ADAMS, John, LL. D., an American teacher and philanthropist, born in Canterbury, Conn., in 1772, died in Jacksonville, Ill., April 24, 1863. He was a son of John Adams, an officer in the revolutionary army from Connecticut, and graduated at Yale college in 1795. Until 1798 he taught the academy in his native town; from 1800 to 1803 he was rector of Plainfield academy; from 1803 to 1810 principal of Bacon academy, Colchester, Conn.; and from 1810 to 1833 principal of Phillips academy, Andover, Mass. He was during this period also one of the founders of several of the national benevolent societies. After being thus engaged in teaching for 36 years, he resigned and removed to Illinois, where he was instrumental in introducing some valuable modifications into the school laws; and when past 70 years of age he organized several hundred Sunday schools in different parts of the state. He published several essays on the training of the young, and left others in manuscript.

ADAMS, John Couch, an English astronomer, born of humble parentage near Bodmin, June 5, 1819. He is a fellow of Pembroke college, Cambridge, England, and shares with Leverrier the honor of having calculated the place of the planet Neptune before it had been recognized by sight. He early showed great powers, and in 1841, while in St. John's college, made his first computation of Neptune's place. In 1844-'6 he renewed his calculations, and communicated the results to Professors Challis and Airy; but he did not publish them, and therefore Leverrier, who soon after attained and published similar results, has reaped the larger share of glory. The calculations of both mathematicians were formed on the motions of the planet Uranus, which was drawn aside from its expected course by the attraction of Neptune. In 1858 Adams was appointed Lowndean professor of astronomy at Cambridge.

ADAMS, John Quincy, sixth president of the United States, eldest son of President John Adams, born in Braintree, July 11, 1767, died in Washington, Feb. 23, 1848. The origin of his name was thus stated by himself: "My great-grandfather, John Quincy, was dying when I was baptized, and his daughter, my

grandmother, requested I might receive his name. This fact, recorded by my father, has connected with my name a charm of mingled sensibility and devotion. It was filial tenderness that gave the name—it was the name of one passing from earth to immortality. These have been through life perpetual admonitions to do nothing unworthy of it." John Adams, having been appointed minister to France, took with him as companion his son John Quincy, then in his 11th year. The voyage from Boston to Bordeaux was tempestuous; the travel by land from Bordeaux to Paris was rapid and fatiguing; but the young Adams, as appears from his father's published diary, conducted and sustained himself through both voyage and travels, and also during their residence at Paris, to his father's entire satisfaction. Placed at a school near Paris, he made rapid progress both in the French language and in his general studies. His health was perfect, and his father wrote to his mother that he attracted general attention wherever he went by his vigor of body, his vivacity of mind, and his constant good humor. After a stay in France of near a year and a half—several months of which were spent at Nantes waiting for a passage home—John Quincy Adams came back with his father in a French frigate. While at sea he taught English to his fellow passengers, the French ambassador to the United States, De la Luzerne, and his secretary, M. Marbois. The following is an extract from his father's diary, under date of June 20, 1779: "The chevalier de la Luzerne and M. Marbois are in raptures with my son. They get him to teach them the language. I found this morning the ambassador seated on the cushion in our stateroom, M. Marbois in his cot, at his left hand, and my son stretched out in his at his right, the ambassador reading out loud in Blackstone's 'Discourse' at his entrance on his professorship of the common law at the university, and my son correcting the pronunciation of every word and syllable and letter. The ambassador said he was astonished at my son's knowledge; that he was a master of his own language like a professor. M. Marbois said, 'Your son teaches us more than you; he has *point de grâce, point d'éloges*. He shows us no mercy, and makes us no compliments. We must have Mr. John.'" Character is very early developed, and John Q. Adams retained much of this same style of teaching to the end of his life. After remaining at home three months and a half, John Q. Adams, now in his 13th year, sailed again in the same French frigate, as his father's companion on his second diplomatic mission to Europe. Arriving at Paris in February, 1780, he was again placed at school, where he remained till August. He then went with his father to Holland, where, after some months' tuition at a school in Amsterdam, he was sent about the end of the year to the university of Leyden. His father's secretary of legation, Francis

Dana (afterward chief justice of Massachusetts), having been appointed minister to Russia, he took with him as his private secretary John Q. Adams, then in his 15th year. Having discharged the duties of this position for 14 months to Dana's entire satisfaction, the latter not having succeeded in getting recognized as minister, young Adams left St. Petersburg, and, travelling back alone, returned leisurely through Sweden and Denmark, and by Hamburg and Bremen, to the Hague, where he resumed his studies. In October, 1783, the treaty of peace having been signed, John Q. Adams attended his father on his first visit to England. Returning with him, he spent the year 1784 in Paris, where the whole family was now collected. His father having been appointed minister to Great Britain, he accompanied the family to London, but soon after, with a view to the completion of his education, returned home to Massachusetts. In 1786 he entered the junior class at Harvard college. He graduated in 1788, and immediately after entered the office of Theophilus Parsons, afterward well known as chief justice of Massachusetts. Here he remained for three years. In 1791 he was admitted to the bar, when he opened a law office in Boston, and in the course of four years he gradually attained practice enough to pay his expenses. He did not, however, confine himself entirely to the law. A series of articles which he published in the "Boston Centinel," with the signature of Publicola—a reply to some portions of Thomas Paine's "Rights of Man"—attracted a good deal of attention not only at home but in England, where these papers were republished and ascribed to his father. In another series of articles in the same journal, signed Marcellus, published in 1793, he defended Washington's policy of neutrality. In a third series, signed Columbus, published the same year, he reviewed the conduct of Genet, the French ambassador, in relation to the same subject. These writings drew attention toward him, and in May, 1794, Washington appointed him minister to the Hague. Upon his arrival there he found things in such confusion, owing to the French invasion, that after a few months' residence he thought of returning; but, by the remonstrances of Washington, who predicted for him a distinguished diplomatic career, he was induced to remain. In 1795 he had occasion to visit London to transact some business with Thomas Pinckney, who after Mr. Jay's departure had resumed the embassy at that court. The American consul at London was Joshua Johnson of Maryland, brother of Thomas Johnson, one of the signers of the declaration of independence, and a judge of the United States supreme court. Mr. Joshua Johnson had formerly been a merchant at Nantes, where in 1779 the Adamses had made his acquaintance. He had by this time a grown-up daughter, with whom young Adams now formed an intimacy, which resulted in mar-

riage on July 27, 1797. Previously to this event, and shortly before the close of Washington's administration, John Q. Adams had been appointed minister to Portugal; but his father, on becoming president, changed his destination to Berlin. In thus promoting his own son, John Adams acted by the written advice of Washington, who expressed his decided opinion that young Adams was the ablest person in the American diplomatic service, and that merited promotion ought not to be withheld from him merely because he was the president's son. He arrived at Berlin shortly after his marriage, in the autumn of 1797. In 1798 he received an additional commission to negotiate a treaty of commerce with Sweden. While residing at Berlin, with a view to perfecting himself in the German language, he made a translation into English of Wieland's "Oberon," and would have published it but for the appearance about that time of a translation by Sotheby. In 1800 he travelled through Silesia, of which tour he wrote an account in a series of letters to his brother which were published, though without the writer's knowledge, in the "Port Folio," a weekly paper at Philadelphia. These letters were collected and published in a volume in London, and, being translated into French and German, had a wide circulation. On the accession of Mr. Jefferson to the presidency, John Q. Adams was recalled; but he had previously succeeded in negotiating a treaty of commerce with Prussia. Returning to Boston, he again opened a law office there. In 1802 he was elected from Suffolk county (which includes Boston) to the Massachusetts senate, and the next year was chosen by the legislature a senator in congress from Massachusetts. He owed this position to the federal party of Massachusetts, and for four years he continued to sustain their views; but on the question of the embargo recommended by Jefferson he separated from them. The Massachusetts election in the preceding spring had resulted in the success of the Jeffersonian party, who elected their candidates for governor and lieutenant governor, and a majority in both branches of the legislature. At the time when the embargo was proposed by the president to congress, it seemed probable that the question of Adams's reelection to the senate would have to be decided by a legislature favorable to the views of the national administration; and the support which Adams gave to that measure was charged by the federalists to the hope of securing his reelection and the favor of a party whose predominance seemed at length established, not merely in the nation, but in Massachusetts also. This course on his part led to a warm controversy between him and his colleague in the senate, Timothy Pickering, who now made the same charges of treacherous selfishness against the son which he had formerly brought against the father. Pickering addressed a letter to Governor Sullivan of Massachusetts, in which he forcibly stated his ob-

jections to the embargo, which he represented as the first step toward a war with Great Britain, a step into which the administration had been led, as he maintained, by French threats or French seduction. This letter Pickering requested the governor to lay before the legislature, which Sullivan refused to do, on the ground that it was "seditious and disorganizing." It found its way, however, into the newspapers, and Adams replied to it through the same medium. In this reply he expressed his conviction that the whole of the difficulties in which the United States were involved on the question of neutral rights, including the issue of Bonaparte's Berlin and Milan decrees, had originated in the unwarrantable maritime pretensions of Great Britain. He even went so far as to represent the late British orders in council, issued nominally in retaliation for the Berlin decree, as a first step on the part of Great Britain toward bringing back the United States to colonial subjection. Giving emphatic expression to suspicions and to an antipathy which, as to the Hamiltonian or Essex junto section of the federalists, he had imbibed from his father, he broadly hinted that Pickering and his special party friends were quite ready to side with Great Britain in the new enterprise which he ascribed to her of re-subjecting America. Although Sullivan had been re-elected governor, the embargo had operated to give the federalists a small majority in both branches of the Massachusetts legislature; and when the question of the choice of senator came up, Adams was dropped, and Lloyd, a Boston merchant, chosen in his place. Adams thereupon declined to sit for the remaining short session of his term, resigned his senatorship, and retired to private life. He had previously, however, secured, in addition to his practice as a lawyer, a new resource and employment, in the post of professor of rhetoric and belles-lettres at Harvard college. He entered upon this professorship in 1806, upon condition of not being obliged to reside at Cambridge, and for three years following discharged the duties of it, delivering lectures, the first, it is said, ever read in any American college, and conducting exercises in declamation. His lectures, which were printed in 1810, once possessed a considerable reputation, but are now entirely neglected. The winter subsequent to his resignation he visited Washington, nominally for the purpose of attending the supreme court. During this visit he sought and obtained a confidential interview with Jefferson, in which he distinctly brought against a portion of the federal leaders the charge of a treasonable design of dissolving the Union and forming a separate northern confederacy. The same charge, thus privately made, he not long after repeated in print, in a review of the writings of Fisher Ames, which he published in numbers in the "Boston Patriot." Such was the origin of a charge which for the next ten or fifteen years strongly affected the admin-

istration of the government, and which, penetrating deeply into the popular mind, made the leading statesmen of New England objects at once of dread and hatred, deprived New England for a considerable period of its natural weight in public affairs, and had a decisive influence in curtailing to a single term the presidential office, to which John Q. Adams himself afterward attained. That he was sincere in bringing this charge there is little room for doubt. The proof, however, which he presented at the time or afterward of the truth of this plot, was sufficiently slender. It was said to have originated with a few federal members of congress; in consequence of the annexation of Louisiana—a measure which Adams had himself opposed, being one of the six senators who voted against it—and the threatened destruction, by the addition of so much new western and southern territory, of the political influence of the northern and eastern states. These dissatisfied members of congress, so Adams alleged, had proposed to have a meeting at Boston, at which Hamilton was to have been present. It was admitted that Hamilton disapproved of the scheme, and yet his reasons for accepting Burr's challenge were cited as proof that he anticipated a civil war and the being called upon to take a leading part in it. Such seems to have been about the whole of this alleged plot, carefully concealed, as Adams admitted, from the great body of the federalists, and unknown even to the greater part of their leaders, including one so conspicuous as Ames. We shall have occasion at a subsequent period of Mr. Adams's life to refer again to this subject. It should be added now, however, that this revelation was among the reasons by which Adams pressed Jefferson to consent to the repeal of the embargo, for which he had himself voted, but which had provoked in all the maritime parts of the country, and especially in New England, a very violent hostility, and which could not be persisted in, as Adams thought, without leading to open and violent resistance, and so affording opportunity to the plotters against the integrity of the Union. Immediately after Madison's accession to the presidency, he nominated Mr. Adams as minister to Russia. Since the time that Adams, while yet a boy, had visited St. Petersburg as private secretary to an unrecognized minister, the United States had had no ambassador at that court. The senate, not yet satisfied of the expediency of opening diplomatic relations in that quarter, though the same thing had been recommended by Jefferson, refused to confirm the nomination. However, a few months after, the nomination was renewed, and with better success. John Adams, who did not like being thus separated from his son, saw in this appointment only a sort of political banishment intended on the part of the Virginia politicians to remove a dreaded competitor out of the way. Yet in fact, by removing John Q. Adams from the immediate theatre of contention at home,

it contributed not a little to his subsequent political promotion. He was himself, as we may judge, well satisfied to escape from the political commotion which he had raised; for when, after various unsuccessful attempts to fill a vacancy on the supreme bench of the United States, he was nominated and confirmed as a judge (for the New England circuit), in spite of the wishes of his father he declined the nomination, preferring to remain as ambassador at St. Petersburg, where he was now established with his family. He was well received in Russia. His official duties were not very arduous. Part of his leisure he employed in writing a series of "Letters," since published, addressed to his sons, on "The Bible and its Teachings"; a pious work, but not otherwise of particular value or merit. The disputes and collisions between Great Britain and the United States having finally terminated in war, through the influence of Mr. Adams the emperor of Russia was induced to offer himself as mediator, and in July, 1813, Adams was joined by Mr. Bayard, and afterward by Mr. Gallatin, those gentlemen having been appointed in conjunction with himself to negotiate a peace. Great Britain, however, refused to treat under the mediation of Russia. She proposed instead an independent negotiation at London or Gothenburg, for which Ghent was afterward substituted. This proposition having been accepted on the part of the United States government, Mr. Adams arrived at Ghent in June, 1814, and after a protracted negotiation of six months, in which Jonathan Russell and Henry Clay were associated, peace was finally concluded Dec. 24, 1814. No attempt whatever was made to limit the maritime pretensions of Great Britain, in resistance to which the war had originated, and against which Mr. Adams, in joining the administration party, had so decidedly pronounced. The skill and eloquence of the American commissioners found ample scope in warding off the pretensions of Great Britain to portions of territory occupied by her, or at least to act as protector to the Indian tribes within the limits of the United States. Some attempt was also made to limit our fishing rights, and Mr. Adams was now instrumental, as his father had been before him, in maintaining unimpaired our enjoyment of the ocean fisheries. Previous to proceeding to London to execute a new commission to negotiate in conjunction with Clay and Gallatin a treaty of commerce, Adams visited Paris, where he witnessed the return of Napoleon from Elba and the brief empire of the hundred days. Here his family joined him after a long and perilous journey from St. Petersburg, and on the 25th of May he joined Clay and Gallatin in London: in conjunction with whom, on July 13, 1815, he signed a commercial convention with Great Britain. This business finished, Adams still remained at London as resident minister.—Upon the accession of Monroe to the presidency (1817) he offered

Mr. Adams the post of secretary of state, to fill which he returned home, after an absence of eight years. The reestablishment of peace in Europe having removed former grounds of contention, a political lull had succeeded, and a new organization of parties now began to take place, especially on the subjects of protection to American manufactures and expenditures from the United States treasury for internal improvements. There still remained, however, to be disposed of, some questions of moment more immediately connected with Mr. Adams's position as secretary of state. Gen. Jackson, having been consulted on the subject by Monroe, had heartily approved of the appointment of Mr. Adams to that department. Adams no less warmly supported in the cabinet, against Mr. Calhoun's proposition of censure, the conduct of Gen. Jackson in invading Florida, hanging Arbuthnot and Ambrister, and taking military possession of St. Mark's and Pensacola. Those proceedings he also sustained with no less zeal in his diplomatic correspondence with the Spanish minister—an important correspondence, having reference to the boundaries of Florida and Louisiana, and the claims of America on Spain for commercial depredations. Though as a senator Adams had voted against the Louisiana treaty, on the ground that the federal constitution gave no power to acquire territory, he now as secretary of state pushed American claims under that treaty to the extreme lengths, insisting that this cession included not merely Florida to the Perdido, but Texas to the Rio Grande. Finally, in consideration of the cession of Florida, the United States agreeing to pay \$5,000,000 for it, to be applied to the extinction of American mercantile claims against Spain, Adams compromised matters by agreeing to the Sabine, the Red river, the upper Arkansas, the crest of the Rocky mountains, and the parallel of 42° N. lat., as the boundary of Louisiana; and upon this basis a treaty was arranged. This treaty was his principal achievement as secretary of state. After some hesitation, Mr. Adams finally yielded to the policy warmly urged by Henry Clay of recognizing the independence of the late Spanish American colonies. An elaborate report which he made in his official capacity on weights and measures secured him the credit of extensive scientific acquirements. Toward the close of Monroe's first term came up the great question of the admission of Missouri as a slave state, and the extension of slavery or its prohibition throughout the unsettled territory north and west of Missouri. The Missouri compromise having at length, after violent agitations at Washington and throughout the country, received the sanction of congress, Monroe, upon being called upon to sign the bill, submitted two questions to his cabinet: First, had congress the constitutional power to prohibit slavery in a territory? and second, was the term "for ever," used in the prohibitive clause of the Missouri bill, to be un-

derstood as referring only to the territorial condition of the district embraced in it, or must it be understood to extend to such states as might be erected out of it? These questions grew out of the circumstance that the southern members of congress had denied any power in congress to prohibit slavery in a state, and therefore any right to refuse to admit Missouri into the Union on the ground that her constitution established slavery. Those of them who supported the compromise admitted, however, a power of imposing conditions on territories; as necessarily implied in the power to erect them. On the first of these questions all the cabinet declared themselves in the affirmative. As to the second question, Adams thought that the term "for ever" must be understood to mean for ever, and that the prohibition of slavery, instead of ceasing with the territorial condition of the district, would under the act of congress extend to any states that might at any time be erected out of it. The other members of the cabinet, including Thompson of New York (except Adams, the only other northern man in it, and soon after made judge of the supreme federal court), were all of opinion that the "for ever" in question was only a territorial for ever, and that it did not and would not operate to prevent any states that might be organized out of this territory from establishing or prohibiting slavery as they chose. But to prevent this delicate point from being mooted, and to give to the cabinet an appearance of unanimity, at Mr. Calhoun's suggestion the second question was modified so as to read, "Is the proviso as it stands in the bill constitutional?" To this question all the members returned the brief answer "Yes," and on the strength of their apparently unanimous opinion (ordered to be deposited in the archives of the state department, whence, like some other valuable historical papers, it has since disappeared), Monroe signed the bill. We owe this piece of secret history to an extract which has been published from Mr. Adams's diary, from which it also appears that he still strongly entertained the same sentiment of opposition to southern ideas, institutions, and predominancy, which had led him to vote against the annexation of Louisiana. But the time was not yet come for the open avowal of his opinions or for acting upon them. Least of all were the present crisis and Adams's position favorable to such a course.—No sooner had Monroe entered upon his second term of office (1821) than the question of who should be his successor began to be vehemently agitated. Of the five members of his cabinet, no fewer than three, Adams, Crawford, and Calhoun, were brought forward as candidates, as were also, outside the cabinet, Gen. Jackson and Henry Clay. Crawford obtained the congressional caucus nomination, according to the usage which then prevailed; but this nomination had no weight with the partisans of the other candidates. To support Adams, the federal party of Massachusetts—the only state in which that party could

be said to maintain an organized existence, and even there it had lately lost the control of the state government—amalgamated with the democratic party of that state; and the same union took place throughout New England, and partially in New York, New Jersey, Delaware, and Maryland. All the federalists, however, did not come into this arrangement. Some of the more persistent among them refused to support Adams. The aged Timothy Pickering, his former senatorial colleague, made a violent attack upon him in a printed pamphlet, founded on his former separation from the federal party. As a general thing, however, the greater part of the old federalists throughout the country gave in their adhesion to Adams—a circumstance urged by his opponents as going to show that he was still but a federalist in a democratic disguise, and not entitled to the support of the democratic party. From the earliest history of the United States as an independent nation, Virginia and New England ideas had contended for predominancy and control. Notwithstanding his former abandonment of New England at the time of the embargo, in the present contest Mr. Adams represented the New England which was in fact synonymous with the federal idea. Of course he suffered greatly from that bitter dislike of New England, which in the preceding quarter of a century had been laboriously and assiduously instilled into the people not merely of the southern but of the western states, and which he had himself, as we have seen, contributed to aggravate. The election resulted in giving to Adams all the votes of New England, 26 votes from New York, 1 from Delaware, 3 from Maryland, 2 from Louisiana, and 1 from Illinois—84 in all; while Jackson had 99—those of Pennsylvania, New Jersey, Indiana, and 2 of the 3 votes of Illinois among the number. Crawford had 41, and Clay had 37, including the votes of Kentucky and Ohio. Calhoun, who had previously withdrawn from the contest, was chosen vice president almost unanimously. There being no choice by the people, the election came into the house, where, by the influence of Clay, Adams was chosen at the first ballot—13 states voting for him, 7 for Jackson, and 4 for Crawford. Jefferson, in a letter a few days before to John Adams, had characterized the decision between John Quincy Adams and Jackson—the only two candidates really before the house—as involving the question whether he and his correspondent were to end their days "under a civil or military government." It is probable that Jefferson's favorite candidate had been Crawford, who received the vote of Virginia; but by nobody had Jackson been more vehemently opposed as the backwoods, uncivilized, and military candidate than by the supporters of Crawford, who had painted in very strong colors the probable barbarizing consequences of Jackson's election. Crawford himself, in a subsequent letter to Clay, most decidedly approved of Clay's preference of Adams to Jackson. No sooner,

however, had Adams entered upon the presidency (March 4, 1825), with Clay as his secretary of state, than a coalition was formed between the late supporters of Crawford and Jackson, with the understanding that Jackson should be their candidate, and with the resolute determination to break down the administration of Mr. Adams, and to prevent his reelection. For this purpose no effort was spared. The Crawford presses, which had abused Jackson, now began to sing praises to him. Adams, considering himself the successor to Monroe in the regular democratic line, and wishing to impress that fact on the public, made few or no removals from office, and when vacancies occurred hardly ventured to appoint a single federalist—a proscription under which that party had labored now for a quarter of a century, and to which Adams's own charges and denunciations had in fact contributed. It was well known that as to this subject Jackson entertained very liberal views; in fact, that he had advised Monroe upon his accession to a much more liberal course in appointing federalists to office than Monroe had seen fit to adopt. Hence, especially in all those states where the opposition was predominant, many enterprising young federalists mustered to the side of Jackson, some of them even joining loudly in those charges of secret federalism against Adams, and in appeals to the long cherished prejudices against New England, which were conspicuous weapons in the party warfare of that day. The new party, assuming to themselves the title of democrats, refused to accord it to Adams and his supporters, to many of whom, indeed, it was not very agreeable, and who invented for themselves the new name of "National Republicans." Some of these young federalists, transformed so suddenly into democrats and Jackson men, hit upon another party expedient no less effective. Even before the election they had gone to Jackson with the story of a secret bargain between Adams and Clay, to result in Adams's election and Clay's appointment as secretary of state; and the charge of bargain and corruption thus originated, and taken up even by Jackson himself, was loudly reechoed after the election, to the damage of both Clay and Adams. The new administration endeavored to strengthen itself by assuming the championship of internal improvements, which had hitherto been Calhoun's specialty, and of protection to domestic industry, of which Clay had been a leading advocate, and which just before Adams's accession had carried the enactment of the tariff of 1824. Although the tobacco and cotton growing states were strongly opposed to protection, yet that idea was at this time far too popular in the middle states to be repudiated. The supporters of Gen. Jackson, at least in the northern and middle states, represented him and themselves as in favor of a "moderate" and "judicious" tariff, as opposed to the high tariff policy which they ascribed to Adams and Clay. In this position of parties, all

the free-traders north and south joined the opposition, including for the most part the powerful navigating interest of New England and the importing interest of New York, thus carrying over to that side a large additional section of the old federal party. Upon the internal improvement question, the opposition, notwithstanding that Calhoun was one of their principal leaders, took more decisive ground, going so far as to deny, as Crawford formerly had done in opposition to Calhoun, the constitutional authority of congress to vote money for that purpose. As additional means of affecting popular opinion, loud charges of extravagance were brought against the government, whose expenses, exclusive of the public debt, scarcely amounted to thirteen millions a year, and retrenchment and reform were loudly promised in case the opposition should triumph. This was for the people. To the politicians another more inviting lure was held out. From Adams's peculiar position in relation to those whom he found in office, he had, as we have seen, nothing in that way to promise his supporters. He did not even dare to remove men apparently hostile to him, while the opposition held out the prospect, in case of their triumph, of a general sweep of the present officeholders—at least of such as were not strongly on their side—and the distribution of their places as spoils to the victors—rewards, that is, for electioneering services. The debates of congress at this period were largely made up of electioneering harangues; and to give free scope to the remarks of John Randolph and other opposition senators, Mr. Calhoun started and acted upon the idea that as presiding officer of the senate he had no authority to call any senator to order. It was in vain to struggle against this combination, which, in the latter part of Mr. Adams's presidential term, had a majority against him in both houses of congress. Nor was his administration any more fortunate in its exterior relations. The congress of Panama, from which much had been hoped in the way of placing the United States at the head of a great American confederacy, was substantially defeated, as to any participation of the United States in it, by the delays induced by the opposition, while an unlucky quarrel with Great Britain as to trade with the West Indies ended in the entire suspension of that traffic. It appears also that an attempt was made by Clay and Adams to purchase Cuba—a measure which might have proved very acceptable at the south, but Spain totally refused to listen to their offers. As against the solid combination of the opposition, supported by the name and prestige of the old democratic party, the game had been a desperate one from the beginning. In the eastern states Mr. Adams was pretty well able to hold his own, and in those states, at the second election, he obtained about as many votes as before. But Kentucky and Ohio, in which the popular feeling against New England was greatly embittered, alto-

gether failed him. Mr. Clay was unable to help him to a single vote. In this desperate emergency, finding his office slipping from under him, Mr. Adams made a most unfortunate effort to retrieve his falling fortunes, in the shape of a letter addressed to the electors of Virginia, in which he claimed their votes on the ground of his services twenty years before in exposing and frustrating the alleged New England plot, which we have already referred to, to dissolve the Union. This ill-judged letter, while it did not gain him a single vote, left him to retire to Quincy (1829)—where he had now become possessor of his father's estate, largely augmented by his own shrewd management—with a new personal and political quarrel on his hands, and with hard feelings and personal antipathies against him, which for a long time had been in abeyance, thus unseasonably revived by himself. Shortly after his return to Massachusetts a correspondence ensued between him and a number of the old federalists and their representatives, which did not tend to mollify matters. No new light was thrown on the alleged plot, though Mr. Adams is understood to have written a book or pamphlet on the subject, which however he refrained from publishing, on the judgment of some friends to whom he submitted it, that it would not better his case. After having successfully kept the political seas for nearly forty years, and that in very stormy times, Mr. Adams was at last stranded, as it seemed, high and dry on a political lee shore. He addressed himself for the moment to arranging the papers and preparing a life of his father; but the fragment of this work which his son has incorporated in his life of his grandfather does not make us regret that he soon abandoned it. He had been a versifier from his youth, and he now published a rhymed performance of some length, founded on the story of the conquest of Ireland ("Dermot McMorrogh," Boston, 1832); but this palpably was not a field in which he was likely to gather laurels.—Though Mr. Adams had now reached an age at which many politicians have voluntarily retired, he had in his temperament too much of innate vigor and indefatigable activity, and too much of the stormy petrel in his character, to make him willing to leave that political vocation to which, both by nature and habit, he was so specially adapted. In fact, the great work of his life remained to be performed. The anti-masonic excitement consequent on the disappearance and alleged murder of William Morgan had, about this time, introduced a new element into the politics of western New York, whence it had spread into Vermont, Massachusetts, Pennsylvania, and in a less degree into other states. This excitement had taken a strong hold of the congressional district in which Mr. Adams lived, and he himself exhibited a deep interest in it. He signalized his zeal against secret societies by exerting himself to procure the abolition of some passwords and secret signs which

formed a part of the ceremonial of the Phi Beta Kappa, a literary society of which branches existed in Harvard and other colleges; and under these circumstances the anti-masons of his district brought him forward as a candidate for congress. He accepted the nomination, and was chosen without opposition, and continued to represent the district till his death, 17 years after. The mass of those who had been his supporters for the presidency had looked, since his failure of a reelection, to Mr. Clay as their head and leader. Mr. Adams entered congress in December, 1831, without party or followers, but in a more independent position than he had ever yet occupied. Shortly after his return to public life he was nominated by the anti-masons as their candidate for governor of Massachusetts. The politics of Massachusetts were at that time in a very disorganized state, and a strong effort was made by the Everetts and other personal friends of Mr. Adams, and was favored by Mr. Webster, to induce the so-called national republican party to accept the nomination of Mr. Adams thus made. But for the feeling against him which his Virginia letter had aroused among the old federalists, this effort would probably have been successful. As it was, the national republicans as well as the supporters of the administration each nominated a separate candidate for governor. There was no choice by the people, but as the national republicans carried a majority in the legislature, their candidate, John Davis, was elected over Adams's head (1834)—a disappointment which tended to place him in a still more independent political position. He gave, however, a general support in congress to that party which had sustained his own administration. He strongly opposed the nullifiers; yet, as chairman of the committee on manufactures, he strove to discover some middle ground on which the vexed question of the tariff might be satisfactorily settled. On the question of the removal of the deposits he went with the party which now began to take the name of whigs—including in that denomination not merely the old national republicans, but a certain number, especially at the south, of deserters from the Jackson ranks. In the affair of the dispute with France in 1835, about the delay in paying the indemnity, which had been stipulated by treaty, for maritime spoiliations in Bonaparte's time, true to his pugnacious temperament, he supported Jackson's proposition for issuing letters of marque and reprisal, no less energetically than he had formerly supported Jefferson's embargo; and by a very singular coincidence, this course, like that, cost him a seat in the United States senate. At this very time the Massachusetts legislature were employed in filling an approaching vacancy in that body. Mr. Adams's friends had brought him forward as a candidate, and he was more than once chosen by the state senate. The house, however, did not concur, but proposed John Davis instead. This question was still pending, with

a fair prospect of a decision in Adams's favor, when his speech in favor of reprisals on France, which did not correspond with the sentiment of Massachusetts, caused him to be abandoned by his supporters in the state senate, and led to the election of Davis, who had before beaten him as governor. Thus again forcibly cut loose from all party connections, Mr. Adams was left at liberty to follow the bent of his own daring and energetic spirit. The abolitionists had now begun to appear on the political stage, but in the prevailing anxiety to avoid giving offence to the South, reference was seldom made to them on the floor of congress except with disclaimers of sympathy, if not with expressions of detestation. The measure principally employed by the abolitionists at that time was the presentation of petitions for the abolition of slavery in the District of Columbia and the territories. To get rid of this importunity, congress had adopted rules which were maintained by Mr. Adams to be inconsistent with the right of petition itself. In this emergency he stepped forward as the champion and guardian of that right. Though he had taken the position of being opposed to the legislation asked for by the abolitionists, as not reasonable or expedient for the moment, he still insisted on their right to be heard. Upon this point he fought for years a battle which drew all eyes upon him as the representative of a principle which found in him an unflinching advocate and indefatigable champion. This new and eminent position was one which Mr. Adams was perfectly adapted to fill. With an iron constitution, strengthened by an active and abstemious life, there was, during his long term of service in congress, not a single member who equalled him, notwithstanding his great age, in capacity for application and powers of endurance; certainly not one whose attendance upon the business of the house was so exact and unremitting. In acquired knowledge, whether by books or personal experience, he far surpassed any of his fellow members; and what was of greater consequence, his stores of knowledge were always at hand and ready for use. Though his voice was weak, in consequence of which the members usually crowded about him when he spoke, he never became exhausted with fatigue; and though his manner was not pleasing and had little variety, yet the peculiar views which he took, and the copiousness and novelty of his illustrations, always held his audience in profound attention. Though he had the appearance often, especially to strangers, of speaking in a passion, at least in ill humor, and of laboring under a degree of excitement, he was in fact perfectly self-possessed, and in the midst of the storms and tumults which he raised about him never lost in the slightest degree his own self-control. We have no space to dwell on the history of his congressional career, which would fill a volume; but we must not omit to notice his defeat, in February, 1837, of his opponents on the question of a censure upon

him for sending up to the speaker a petition purporting to come from slaves, as one of the most signal instances of his triumph. His undaunted bearing, his courage and determination, which no threats and no tumults could suppress, soon drew around him, as a moral aid and support, a body of external applauders and admirers; so that from this time forward he became the representative not merely of one of the districts of Massachusetts, but of a great embryo party, the party in fact of northern sentiments and ideas, a party which he himself had contributed his share toward burying under ground, but which he now labored night and day to help emerge again into life. Nor did Mr. Adams confine his labors on this question to congress. In the famous Amistad case—the case of certain newly imported Africans, who, while being transported from one port of Cuba to another, had made themselves masters of the vessel and had escaped to the coast of the United States—he appeared in the federal supreme court as counsel for the Africans, in opposition to the claim set up by their Spanish purchasers from whom they had escaped; a claim zealously urged not merely by the Spanish government, but covertly also by Mr. Van Buren, then president of the United States. Indeed, he seldom declined any occasion in his power of addressing an audience. The following may serve as a specimen: He left Boston one Monday morning to attend the opening of congress. That same evening he delivered an address before the young men's institute in Hartford, and the next evening a similar lecture before a similar institute in New Haven. On Wednesday evening he lectured before the New York lyceum; on Thursday evening he delivered an address in Brooklyn, and on Friday evening another lecture in New York, whence he proceeded next day to Washington to be present at the opening of congress on the following Monday. Though greatly engrossed by the subject of slavery, he did not confine his attention to it. Few leading topics came before the house on which he did not speak. In the organization of the house in December, 1839, which had been delayed for four days by the persistency of the clerk in undertaking to reject certain members from New Jersey who had certificates of election, but as the clerk thought improperly granted, Mr. Adams finally intervened with great energy and effect, and to general satisfaction. It was chiefly through his activity and perseverance that the Smithsonian institution was organized. In 1845 the obnoxious "gag rule," originally enacted in 1836, was rescinded, and from that moment Mr. Adams somewhat relaxed his zeal and labors. He began, indeed, to feel at last the effects of age. His health had been somewhat shaken by a heavy fall in the house of representatives, caused by his foot catching in the floor matting, by which his shoulder was dislocated and a severe contusion inflicted on his forehead. It rendered him for the moment insensible, and

though it did not prevent his appearance the next day in his seat, he suffered permanently from it. On Nov. 26, 1846, just as he was about to leave Boston for Washington, he experienced a shock of paralysis which kept him from his seat for the next four months. After this he attended congress regularly, but seldom spoke. On Feb. 21, 1848, he had a second attack while occupying his seat in the house. He was taken to the speaker's private room, where he remained in a state seemingly of unconsciousness, though with occasional incoherent utterances, till the 23d, when he expired. His last words are said to have been, "This is the last of earth; I am content."—In addition to his voluminous speeches in congress, many of which were written out by himself, on various subjects, a great number of his acknowledged publications appeared in his lifetime. He left behind him a very voluminous diary, extending from his early youth to his death, one or two valuable fragments from which have already appeared. His journal, which is in the hands of his son, is regarded as a great political treasure. He wrote with great fluency, his manuscript seldom presenting an erasure, but he lacked altogether that idiomatic elegance, force, and simplicity so conspicuous in his father, instead of which his style is swelling, verbose, inflated, and rhetorical. He lacked also, though not without powers of sarcasm, the wit and fancy which sparkled in his father's writings, and still more that spirit of philosophical generalization into which John Adams constantly fell, but which was totally foreign to the intellectual constitution and habits of the son. John Quincy Adams had more learning perhaps, but John Adams had much more genius. In energy, spirit, firmness, and indomitable courage, John Q. Adams was his father's equal; in self-command, in political prudence, and even perhaps in capacity for hard work, his superior. Both will live forever as representatives and embodiments of the spirit and ideas of New England during the periods in which they figured. In some respects John Q. Adams was far more fortunate than his father. The brilliant period of his career was toward its close. The longer he lived the higher he rose, and he died as such men prefer to die, still an admired and trusted champion, with harness on his back and spear in hand. Yet his whole political career, taken together, hardly presents to the close observer a character so uniformly brilliant and unspotted, and so free from the taint of selfishness, as that of his father. In personal appearance, and in general temperament and character, the resemblance between the father and the son was close. Both had very strong feelings and warm prejudices, though of the two John Quincy appears to have been the less vehement by nature, and also the better under control. Like his father, he was an economical housekeeper and judicious financier, and he died in possession of a handsome estate.—See

"Life and Public Services of J. Q. Adams," by William H. Seward (12mo, Auburn, 1849), and "Life of J. Q. Adams," by Josiah Quincy (Boston, 1858).

ADAMS, Nehemiah, D. D., an American clergyman, born in Salem, Mass., Feb. 19, 1806. He graduated at Harvard college in 1826, studied divinity at Andover, settled as colleague pastor with the Rev. Dr. Holmes over the first Congregational church in Cambridge, Dec. 17, 1829, resigned March 17, 1834, and was installed over the Essex street church in Boston, March 26, 1834. He took an active part in the controversy with the Unitarians, and published several works of a polemic and devotional character. The principal of these are: "Remarks on the Unitarian Belief," "The Friends of Christ in the New Testament" (Boston, 1853), and "Life of John Eliot." He was also a frequent contributor to the "Spirit of the Pilgrims," a religious periodical (Boston, 1826-'33), devoted to the defence of the puritan faith against the encroachments of modern liberalism. He has also published "Christ a Friend," "Agnes and the Key of her Little Coffin," "Bertha and her Baptism, or the Early Saved," works of religious consolation for the afflicted. In 1853 Dr. Adams spent a winter, for the benefit of his health, in Savannah, Georgia, on the plantation of a wealthy slaveholder; and on his return he wrote "A South Side View of Slavery" (1854), in which he gave a highly favorable description of the institution, and especially of its influence on the religious character of the slave. He also published a correspondence on the same subject with Governor Wise of Virginia. After 35 years of pastoral labor with the Essex street church, in 1869, in consequence of failing health, he resigned his pastorate. His people refused to accept his resignation, but procured an associate minister, and gave him a long leave of absence, which he employed in making a voyage round the world, spending much time in the Sandwich Islands. He returned in 1871 with improved health.

ADAMS, Samuel, a leading actor in the American revolution, born in Boston, Sept. 27, 1722, died Oct. 2, 1803. His grandfather was a grandson of Henry Adams, the same emigrant from England to Massachusetts from whom John Adams, second president of the United States, traced his descent. These two illustrious coöperators in the American revolution had both the same great-grandfather, a son of Henry Adams. He was prepared for college at the Boston Latin school, then taught by the elder Lovell, and entered at Cambridge in 1736. Previous to the revolution the names of the graduates of Harvard college are arranged in the college catalogue, not alphabetically, but in an order of precedence according to the estimated rank of their families. In a class of 24, John Adams held the 14th place; Samuel Adams, in a class of 22, the 5th. The Boston branch of the Adams family would seem

to have attained to a somewhat higher colonial position than the branch which remained at Braintree. He was graduated A. B. in 1740. His father, Capt. Samuel Adams, had urged his entering the ministry; but he had no taste for this calling, and on leaving college began the study of law. This he relinquished to take a place in the counting house of Mr. Thomas Cushing, where, though active and industrious enough, he displayed conspicuous inaptitude for trade. He began business for himself, and failed. Subsequently he became a partner with his father in a brewery, and after Capt. Adams's death in 1748 he carried on the concern himself. About 1740 Capt. Adams became involved in pecuniary misfortunes through his connection with a banking speculation known as the land bank or manufactory scheme. In efforts on behalf of the unfortunate speculators in this scheme, Samuel Adams found an early introduction to politics, which ultimately became the chief interest and principal employment of his life. Fully to understand the first connection of Samuel Adams with politics, a brief retrospect becomes necessary. The use of paper money, first introduced into Massachusetts in 1690, and which had speedily driven coin out of circulation, had, in consequence of over-issues, been attended with great depreciation and fluctuations of prices. These issues were made for limited periods, and in consequence of the remonstrances of the English merchants trading to America, orders had been sent to Governor Belcher to agree to no new ones. The circulating paper being gradually absorbed, and the year 1741 being fixed for its complete withdrawal, the effect of this operation was much like that of a bank contraction of our day. The Boston merchants, and indeed the body of the people, complained bitterly of the scarcity of money, and an attempt was made to free Governor Belcher, by withholding his salary, to consent to new issues, or to extend the period of the old. As he proved inflexible, two joint-stock banking companies had been got up: one, called the "silver scheme," proposed to issue £110,000 in notes, redeemable in silver at the end of 10 years; the other, called the land bank or "manufactory scheme" (that in which Adams's father was concerned), undertook to circulate £150,000, which was to be redeemed at the end of 20 years in colonial produce. The "silver scheme" was patronized by the merchants and traders, the land bank by the farmers and mechanics. Belcher zealously opposed both. In spite, however, of the governor's proclamation, notes were issued by both companies, and those of the land bank especially were largely pushed into circulation. That company had 800 stockholders, and held complete control of the Massachusetts house of representatives. Belcher even apprehended an insurrection to compel him to give his consent to the scheme, and his opponents did succeed in obtaining his removal. But this did not avail them, for the operation of

these two Massachusetts banks was cut short by an act of parliament extending to the colonies an act of the previous reign, occasioned by the South sea and other bubble schemes, which prohibited the formation of unincorporated joint-stock companies with more than six partners. The two banking companies were thus compelled to wind up; the partners were held individually liable for the notes, and the "manufactory scheme" especially, the affairs of which remained unsettled for several years, proved ruinous to the few partners who had anything to lose, of whom Adams's father was one. This act of parliament was denounced by the friends of the banks as a violation of the chartered rights of Massachusetts. The young Adams thus entered upon politics as the opponent of parliamentary authority, and as a champion for the body of the citizens—a position which, to a certain extent, his father seems to have occupied before him. How strongly his mind was turned in this direction, appears from the subject he chose for his thesis upon taking his degree of A. M. He proposed as a question, "Whether it be lawful to resist the supreme magistrate, if the commonwealth cannot otherwise be preserved?" as to which he supported the affirmative. Not succeeding in business, he obtained the post of tax collector for the town of Boston, an office which brought him into contact and acquaintance with all the inhabitants, and which obtained for him from his political opponents the cognomen of Samuel the Publican. During the administration of Governor Shirley he was steadily in the opposition. Against Bernard—his influence increasing with his age—he took a still more decided part. From an entry in John Adams's journal, under date of February, 1763, it seems that at that time there were in Boston two clubs—one the "Merchants' Club," the other the "Caucus Club"—accustomed to meet and agree upon persons to be supported for town officers, and that the caucus club used to send committees to consult and agree with the merchants' club as to men and measures. Of this caucus club—a corruption probably of caulkers' club, as having been originally composed of ship-building mechanics—Samuel Adams was then and long had been an active member. Gordon, indeed, traces back the existence and influence of this club to the time of Adams's father. Adams took an active part in all town meetings, at which his energy and courage made him a leader. The instructions given by the town of Boston, in May, 1764, to their newly chosen representatives—the first decided protests from any part of America against Grenville's scheme of parliamentary taxation—were drawn up by him; and he was chosen the next year as one of the three representatives in the general court of the town of Boston, a position which he held for nine years following. Upon his entry into the house he accepted the office of clerk, which not only produced him a small addition to his limited

income, but enabled him also to exercise a certain influence over the course of proceedings. The Massachusetts house of representatives consisted at this time of upward of a hundred members, the most numerous assembly in the colonies. Its debates had begun to attract attention, and a gallery was now first erected for spectators. Besides taking a leading part in the debates, it devolved upon Adams to draw the larger part of the papers put forth by the house in its controversies with Bernard and Hutchinson—an office for which his fluent and eloquent pen, and the mixture in his character of caution with fire, courage, and decision, admirably fitted him. The following account of Samuel Adams, sketched from the life at the period of his entering the house, is found in the diary of John Adams, under date of Dec. 23, 1765: "Adams is zealous, ardent, and keen in the cause; is always for softness, delicacy, and prudence when they will do, but is stanch and stiff and strict and rigid and inflexible in the cause." A previous paragraph had sketched Gray, who afterward joined the tory party, and Thomas Cushing. After a sketch of James Otis, the diary adds: "Adams, I believe, has the most thorough understanding of liberty and her resources in the temper and character of the people, though not in the law and constitution, as well as the most habitual radical love of it, of any of them; also the most correct, genteel, and artful pen. He is a man of refined policy, steadfast integrity, exquisite humanity, fair erudition, and obliging, engaging manners, real as well as professed piety, and a universal good character, unless it should be admitted that he is too attentive to the public and not enough so to himself and his family." Governor Hutchinson—a no less competent observer, but who looked at Adams from an entirely opposite point of view—gives in the 3d volume of his "History of Massachusetts" substantially the same account. He sets down Samuel Adams as the most artful and insinuating politician he had ever known, and the most successful "in robbing men of their characters and calumniating the servants of the crown." He accuses Mr. Adams of "defalcation" as collector of taxes, the only foundation for the charge being that in a period of general commercial distress he had failed to collect the full amounts levied upon the citizens; and Hutchinson adds, by way of comment, "The benefit to the town from his defence of their liberties he supposed an equivalent to his arrears as their collector." While Adams thus devoted himself to politics, it was chiefly the industry and economy of his wife that supported the family. He had married in 1749 Elizabeth, daughter of the Rev. Samuel Checkley of Boston. She died in 1757, and in 1764 he married Elizabeth Wells, daughter of an English merchant who had settled in Boston in 1723. Though poor, Adams was incorruptible. It had been proposed to silence him by the gift of some place under

government; but Hutchinson in a letter to England declared that such was his "obstinacy and inflexible disposition," that no gift nor office would ever conciliate him. The passage of Townsend's act in 1767, and other acts of parliament which evinced a determination to raise a parliamentary revenue in America by taxes on trade, brought the colonists in a body to the ground that taxes on trade, if designed to raise a revenue, were just as much a violation of their rights as any other tax. Adams took a leading part in urging these views, and the petition of the Massachusetts general court to the king agreed to on this occasion, their letter of instruction to their agent in England, and a circular letter addressed to the speakers of the popular branch of the several colonial assemblies, inviting consultation and mutual coöperation for the defence of colonial rights, were all from his pen. Hutchinson states that as early as 1769, some objections having been made to a motion pending in a Boston town meeting that it savored of independence, Adams wound up a speech in defence of it with this bold declaration: "Independent we are, and independent we will be." Upon the occasion of the so-called Boston massacre in March, 1770, Samuel Adams was appointed chairman of a committee to wait upon the governor and council with the vote of a town meeting, to the effect that nothing could restore order and prevent blood and carnage but the immediate removal of the regular troops, who, instead of encamping, as had formerly been usual, on the fortified island in the harbor, known as Castle island, had for the last 18 months, to the great annoyance of the inhabitants, been stationed in the town. Adams entered the council chamber at the head of the committee and delivered his message. Col. Dalrymple, the commander of the troops, was present, as was the commander of the ships of war in the harbor. In reply to the vote of the town presented by the committee, Lieutenant Governor Hutchinson disclaimed any authority over the soldiers; to which Adams replied by referring him to that clause in the provincial charter which declared the governor, or in his absence the lieutenant governor, commander-in-chief of all the military and naval forces in the province. After a consultation with Dalrymple, Hutchinson replied that the colonel was willing to remove one of the regiments if that would satisfy the people. "Sir," said Adams, "if the lieutenant governor, or Col. Dalrymple, or both together, have authority to remove one regiment, they have authority to remove two; and nothing short of the departure of the troops will satisfy the public mind or restore the peace of the province." The energy of Adams prevailed, and both regiments were sent to the castle. The destruction of the tea attempted to be forced on the colonies, the passage of the Boston port bill and of the bill modifying the Massachusetts charter, and the appointment of Gen. Gage

as governor at the head of an army, brought things to a crisis. As Gage entered the harbor of Boston, May 13, 1774, a town meeting at which Adams presided was in session, assembled to take the port bill into consideration, news of which had just arrived. At the June meeting of the general court a continental congress was proposed to assemble at Philadelphia, to which the representatives appointed five delegates, of whom Adams was one; and Gage having thereupon suddenly dissolved the court, the patriots immediately began to organize a distinct government of their own. Transferred thus to Philadelphia, and from the Massachusetts general court to a continental congress, Adams began now to act on a broader scene. His first act was one of conciliation. He was himself a strict Congregationalist, and the recent attempts to extend Episcopacy in America, and the controversy thence arising, had produced a good deal of feeling. A motion by one of the Massachusetts delegates to open the proceedings of the congress with prayer was opposed by Mr. Jay, one of the delegates from New York, on the ground that as there were in that body Episcopalians, Quakers, Anabaptists, Presbyterians, and Congregationalists, they would hardly be able to join in the same act of worship. Thereupon "Mr. Samuel Adams arose"—so wrote John Adams in a letter to his wife describing the scene—"and said he was no bigot, and could hear a prayer from a gentleman of piety and virtue who was at the same time a friend to his country. He was a stranger in Philadelphia, but he had heard that Mr. Duché deserved that character, and therefore he moved that Mr. Duché, an Episcopal clergyman, might be desired to read prayers to the congress." The motion passed, and Duché, at that time the most popular preacher in Philadelphia, appeared the next morning and officiated with great unction. He acted as chaplain to congress for several sessions, but when the British occupied Philadelphia he abandoned the cause of his country, and even had the impudence to write Washington a letter exhorting him to the like piece of treachery. Adams's motion, however, was very well timed. It not only pleased the Episcopalians, a powerful body in New York and predominant at the south, but it also secured for the moment Duché himself, whose example was not without its effect upon others. In this congress and those which followed, Adams, who continued a member for eight years, took an active, decided, and influential part. No one man, perhaps, did so much as he to put the revolution in motion, and to bring about the separation from the mother country, to which, indeed, Gen. Gage bore testimony in excepting him, along with Hancock, from his offer of pardon in case of submission. In administrative talents, however, he was not so conspicuous; and the line of policy which he supported in congress was rather graduated to accord with the feelings, sentiments, and sometimes the prejudices of

the people, than always calculated to meet the actual exigencies of affairs. Together with John Adams he took an active part in the formation of the state constitution of Massachusetts, adopted in 1780. He was a very influential member of the Massachusetts convention called in 1788, to consider the federal constitution; and though opposed to many of its features, he was finally persuaded, along with Hancock, to give it his support, in consideration of certain proposed amendments, of which several were afterward adopted. This decision of the question, so far as Massachusetts was concerned, was of the greatest moment, involving in it the action of other states, and in fact the fate of the new government. The next year Adams was chosen lieutenant governor of Massachusetts, which office he held till 1794, when he was chosen governor as Hancock's successor. He was a warm admirer of the French revolution, and in national politics leaned decidedly to the republican or Jeffersonian party. It was this circumstance, no less than his increasing age and infirmities, that induced him in 1797, the federal party being predominant in Massachusetts, to decline serving longer as governor, and to retire to private life.—A highly characteristic portrait by Copley, which hangs appropriately in Faneuil Hall, has transmitted his features to us. Memorials of his life and service are to be found scattered through the writings of John Adams, who in his old age exerted himself to recall public attention to his colleagues of the revolutionary times. Sullivan, in his "Familiar Letters on Public Characters," describes Samuel Adams as "of common size, muscular form, light blue eyes, fair complexion, and erect in person. He wore a tie wig, cocked hat, and red cloak. His manner was very serious. At the close of his life, and even from early times, he had a tremulous motion of the head, which probably added to the solemnity of his eloquence, as this was in some measure associated with his voice. Having inherited no fortune, and being without a profession, he was, almost down to the close of his life, without resource except in the salaries and emoluments of office, never large, and only eked out by the industry and economy of his wife. Yet those who visited his house found nothing mean or unbecoming his station, since he knew how to combine decency, dignity, and propriety with a small expenditure. At a late period of his life he obtained a competency, but only by a very afflicting event—the death of his only son, of the same name with himself, who, having graduated at Harvard college in 1771, had studied medicine with Dr. Joseph Warren (the famous general), had served as a surgeon through the revolutionary war, and returning home with a broken constitution, had died in 1788. The avails of his claims for services in the army gave his father a competency in his declining years.—In one respect—indeed in many, but we can here refer only to

one—there was a remarkable contrast between Samuel and John Adams. Both, true to their New England origin, were theologians; but John Adams, while to a certain extent a conservative in politics, was quite a neologist in religion. The Arminian heresies of his youthful days had prevented him from studying divinity, and in the correspondence of his extreme old age he appears almost as much a free-thinker as Jefferson himself. Samuel Adams, on the other hand, though to his last days a progressive in politics, was always a decided conservative in religion, adhering with sincere persuasion and firm tenacity to the five points of Calvinism. Nor did this strictness limit itself to doctrine. "At a time," says Edward Everett, "when the new order of things was inducing laxity of manners and a departure from the ancient strictness, Samuel Adams clung with greater tenacity to the wholesome discipline of the fathers." But Mr. Everett scarcely does justice to Mr. Adams's spirit of sociality when he adds, "His only relaxation from business and the cares of life was in the indulgence of a taste for sacred music, for which he was qualified by the possession of a most angelic voice and a soul solemnly impressed with religious sentiment." He was, on the other hand, fond of conversation, and possessed himself a large fund of anecdote.—Besides the state papers of which Adams was either wholly or mainly the author, and his numerous political contributions to the newspapers, of which, however, but few have been identified, there have appeared in print a number of his letters. An oration on American independence, purporting to have been delivered by him in Philadelphia Aug. 1, 1776, and printed in London, is probably spurious, though it is a very favorable imitation of his style, neat, forcible, and pointed, without the least inflation or appearance of effort. In this oration the writer gives the English the title of a "nation of shopkeepers," and it is not impossible that it was hence that Bonaparte borrowed this appellation, which was a favorite one with him, since it is known that the oration was translated into French and published at Paris. Adams's life has been written by W. V. Wells ("Life and Public Services of Samuel Adams," 3 vols. 8vo, Boston, 1865). He left only female descendants, and the name of Adams is no longer borne by any of his blood.

ADAMS, William, D. D., an American clergyman, born in Colchester, Conn., Jan. 25, 1807. He received his early education from his father (see **ADAMS, JOHN, LL. D.**), when principal of Phillips academy, Andover, Mass., and graduated at Yale college in 1827. He studied theology at Andover, and in February, 1831, was ordained as a Congregational minister and pastor at Brighton, Mass. In 1834 he was called to the charge of the Central Presbyterian church, New York city. He has since that time been identified with the Presbyterian

church, and has been (1872) for 38 years the pastor of the same congregation, which since 1853 has been known as the "Madison Square Presbyterian Church." He early attained reputation as a pulpit orator, and has been very prominent in the national benevolent societies. He was moderator of the New School general assembly of 1852, and was active in promoting the reunion between the Old and New School churches in 1870-'71. Besides occasional sermons, addresses, orations, and articles in the reviews, he has published "The Three Gardens: Eden, Gethsemane, and Paradise" (1859); an edition of Isaac Taylor's "Spirit of Hebrew Poetry," with a biographical introduction (1861); "Thanksgiving: Memories of the Day, and Helps to the Habit" (1865); and "Conversations of Jesus Christ with Representative Men" (1868). In 1871 Dr. Adams was elected professor of sacred rhetoric and pastoral theology in the Union theological seminary, New York, but declined the appointment.

ADAMS, William T. (pseudonym, **OLIVER OPTIC**), an American writer of juvenile books, born in Medway, Mass., July 30, 1822. He was for many years a public school teacher in Boston, and now edits "Oliver Optic's Magazine for Boys and Girls." His principal works are "The Boat Club," "Woodville," "Army and Navy," "Young America Abroad," "Starry Flag," and "Lake Shore" series of stories, the "Riverdale Story Books," and "In Doors and Out," a volume of domestic tales.

ADAM'S PEAK, or **Hamazel**, a conical mountain in S. Ceylon, 45 m. S. S. E. of Colombo, 7,420 ft. high, and, with the exception of Pedrotallagalla (which exceeds it by 860 ft.), the highest in the island. The ascent is made by means of a chain fixed to its summit. It is considered sacred by both Buddhists and Mohammedans, who make frequent pilgrimages there during the dry season (January, February, and March). On the summit, which is surrounded by a wall 5 ft. high, with two openings for the admission of pilgrims, there is the impression of a gigantic foot in the rock, said by the natives to be that of Buddha when he stepped from this peak to the adjacent kingdom of Siam; but ascribed by the Mohammedans to Adam after his expulsion from paradise (placed in the vicinity of Ceylon), whence the peak derives its name.

ADANA, a town of Turkey, in S. E. Asia Minor, capital of a sanjak, on the river Sihun (anc. Sarus), 25 m. N. E. of Tarsus and 60 m. N. W. of Alexandretta; pop. about 30,000. It commands the Cilician passes of the Taurus chain, is well built, and contains interesting ancient remains. The bridge across the Sihun at this point is reported to have been constructed by Justinian, and the castle is also notable. Wool, cotton, corn, wine, and fruit are the staples of its commerce. Pompey colonized the town with conquered Cilician pirates. From 1833 to 1839, in consequence of Ibrahim Pasha's victory at Konieh, the sanjak was in the hands of the Egyptians.

ADANSON, Michel, a French naturalist, of Scotch descent, born at Aix, April 7, 1727, died in Paris, Aug. 3, 1806. At the age of 21 he went at his own cost, though of very limited fortune, to the French colony of Senegal to study nature. After five years he returned to France with a fine collection. He first attacked the Linnæan method, and his writings paved the way for the acceptance by the scientific world of Jussieu's system. The generic name *Adansonia* was given in his honor to the baobab tree, of which he gave the first scientific account. He was also distinguished for philanthropy, and proposed to found a colony with free negroes in Senegal, which was not, however, favored by the ministry of Louis XV. His name is associated with a plan for a vast cyclopædia of natural history, which the academy had not the courage to take up. He, however, persisted in his ideas, devoting many years to the collection of immense masses of manuscript material. By the revolution he was stripped of everything, and reduced to such abject poverty, that when he was invited in 1798 to take his seat as a member of the reorganized institute (having been a member of the academy since 1759), he was obliged to decline for want of shoes. He afterward received a small pension, in the enjoyment of which he died in his 80th year. His principal works are: *Histoire naturelle du Sénégal* (1 vol. 4to, 1757, including *L'Histoire des coquillages*, the earliest attempt at a scientific classification of shells according to their inhabitants), and *Méthode naturelle pour apprendre à connaître les différentes familles des plantes* (2 vols. 8vo, 1764, written with a phonetic orthography of his own invention). He also contributed many valuable memoirs to the publications of the academy of sciences.

ADAR, the name of the 6th month in the civil year of the Jews, and of the 12th in their ecclesiastical year, answering to parts of February and March. A fast for the death of Moses is observed on the 7th, the fast of Esther on the 13th, and on the 14th and 15th the fast of Purim. A second Adar is intercalated seven times in every nineteen years, in order to harmonize the lunar and solar periods.

ADDA (anc. *Addua*), a river of N. Italy, a tributary of the Po. It rises in the Rætian Alps, flows S. W., S., and S. E. through the Valtellina and Lombardy, and the lakes of Como and Lecce, and enters the Po about 8 m. W. of Cremona. Its course is about 80 m. Lodi, the scene of one of Bonaparte's early triumphs, and Cassano, at which Moreau was defeated in 1799, are on its banks.

ADDER. See VIPER.

ADDINGTON, a S. county of the province of Ontario, Canada, bordering on the bay of Quinté, near the E. end of Lake Ontario; area about 2,000 sq. m.; pop. in 1871, 21,312. The county is about 122 m. long, and from 7 to 18 wide. It has between 20 and 30 lakes, the longest of which, Massanogo, is about 50 m.

long. The northern townships are new and thinly settled. The chief occupations are agriculture and lumbering. Chief town, Bath.

ADDINGTON. I. Henry, Lord Sidmouth, an English statesman, born May 30, 1757, died Feb. 15, 1844. He was the son of Dr. Anthony Addington of Reading, known as the author of treatises on scurvy and on the mortality of beasts, and for his attempt in 1778 to establish a political alliance between the earl of Bute and the earl of Chatham, whose physician he was. This connection with Lord Chatham led to an intimacy between Henry Addington and the younger William Pitt, who induced him to enter parliament in 1784. He was called to the bar in the same year, but never practised. In 1789 he was elected speaker, and continued to support Pitt, but voted against him on the slave question, favoring a gradual emancipation. In 1801 Pitt resigned and Addington took his place as chancellor of the exchequer and first lord of the treasury, and formed a new ministry. He aided in forming the treaty of Amiens in 1802, the objectionable clauses in which were vigorously attacked by Windham and Grenville. But in 1803, when peace was considered dishonorable, he supported a war policy. The prince of Wales, afterward George IV., had a personal dislike to Addington, who was regarded as the chief of the special friends of George III., and the illness of the latter gave the prince opportunity to show his animosity. In 1804 Addington resigned, and the king created him a peer by the title of Viscount Sidmouth (Jan. 12, 1805), and appointed him president of the council, which office he resigned in July. After Pitt's death, Lord Sidmouth entered the ministry of Grenville and Fox (Feb., 1806, to March, 1807), first as lord privy seal and afterward as president of the council. In 1812 Lord Sidmouth was appointed secretary for the home department in Lord Liverpool's ministry. In 1822, on the death of Lord Castlereagh, he resigned his office, but at Lord Liverpool's request retained his seat in the cabinet two years longer. **II. Henry Unwin**, an English diplomatist, a relative of the preceding, born March 24, 1790, died in London, March 6, 1870. He entered the foreign office after leaving Winchester college, and was for upward of 30 years in the diplomatic service in various countries, including the United States, whither he was sent in 1822, and again in 1826. He was under-secretary of state from 1842 to 1854, when on his retirement he was made privy councillor.

ADDISON, a W. county of Vermont, bounded W. by Lake Champlain and drained by Otter creek and its tributaries, which afford excellent water power; area, 750 sq. m.; pop. in 1870, 23,484. Near the lake the surface is almost level, but it becomes rugged and mountainous toward the east. The soil is fertile. The productions in 1870 were 57,725 bushels of wheat, 144,257 of corn, 334,446 of oats, 28,211 of buckwheat, 317,043 of potatoes,

495,771 lbs. of wool, 201,855 of maple sugar, 1,723,437 of butter, 546,047 of cheese, and 114,298 tons of hay. The value of farms was \$16,001,548, and of productions \$3,055,768. The manufacture of cotton, wool, paper, &c., is carried on, and quarries of white and veined marbles are extensively worked. The Rutland and Burlington railroad runs through the county. Capital, Middlebury.

ADDISON, Joseph, an English author, born at Milton, Wiltshire, May 1, 1672, died in Holland house, Kensington, June 17, 1719. He was educated at the Charter House school and at Queen's and Magdalen colleges, Oxford, and was early noted for elegant scholarship, and particularly for his proficiency in Latin versification, which elicited the praise of Boileau. His own tastes would probably have led him to take orders, which his father, the Rev. Launcelot Addison, dean of Lichfield, urged him to do, or to follow an exclusively literary career. But the age was one of too earnest political warfare to permit a young man of talent to keep aloof from party strife, and Addison began to pay court to prominent statesmen in complimentary verses and other offerings to their vanity. He thus secured the friendship and patronage of Lords Somers and Halifax, the former of whom in 1699 obtained for him a travelling pension of £300, by means of which he was enabled to visit France, Germany, and Italy. The death of William III. having removed his friends from power, he lost his pension, was forced to become a travelling tutor, and in 1703 returned to England. In the succeeding year, at the suggestion of Lord Halifax, he commemorated the victory of Blenheim in an indifferent poem entitled "The Campaign," containing, however, one fine simile, which so pleased the lord treasurer Godolphin that he appointed Addison a commissioner of appeal of the excise. From this time until the close of his career, except during the tory administration of Oxford and Bolingbroke, he was scarcely ever without office of some kind. In 1705 he accompanied Halifax to Hanover as secretary of legation. In the succeeding year he was appointed under-secretary of state, and in 1709 secretary to the marquis of Wharton, the lord lieutenant of Ireland, although he remained in London during the greater part of his term of office. He also represented Lostwithiel in parliament from 1708 to 1710, and Malmesbury during the remainder of his life. His career as a legislator was not brilliant, his only attempt to address the house having proved a total failure through loss of self-possession.—Previous to his 37th year Addison's literary productions were few and fragmentary. A book of "Travels" which attracted little attention, the "Dialogues on Medals," some occasional poems and English versions from Virgil and Ovid, and his Latin verses comprised nearly all that he had given to the public. His reputation as a wit and man of letters was nevertheless very great in the London clubs

and coffee houses, then the usual resorts of literary characters; and his sudden appearance in the "Tatler," started by his school friend Steele in 1709, and its successor the "Spectator," as the most brilliant essayist of his time, was by no means a surprise to his friends. Upon his contributions to the "Spectator" his fame now chiefly rests. Commenced on March 1, 1711, it was continued daily till December 6, 1712, when Steele retired and the publication ceased. A year and a half later it was recommenced by Addison, who for a considerable period was its sole contributor. Eighty papers were then added to the 555 already published, and the "Spectator" was finally discontinued on Dec. 20, 1714. Of the 635 essays included in both series, Addison was the author of 274, his contributions being generally identified by some letter in the name of the muse Clio appended to them. He also wrote occasionally for the "Guardian," a successor of the "Spectator." He found this style of composition singularly adapted to his talents and disposition; and in an age artificial and frivolous almost beyond precedent, his essays are natural, decent, and instructive, infused with a serene and cheerful philosophy, and often with an artless gaiety, and written in a diction of almost faultless purity. His papers on Milton, on Sir Roger de Coverley and his friends, and that entitled "The Vision of Mirza," are to this day among the masterpieces of English literature. In the spring of 1713 was produced his tragedy of "Cato," the immediate success of which, owing to the political significance attached to it, to the zeal of friendship, and to the existent standard of dramatic taste, was far beyond its merits as an acting play. Pope wrote the prologue and Dr. Garth the epilogue, and it had a run of 35 nights, and was translated into various European languages. It is now remembered chiefly by the soliloquy of the hero and a few passages which have become standard quotations. The death of Queen Anne having restored his political friends to power, he again held office, first as secretary to the lords justices, then for a while as secretary to the lord lieutenant of Ireland, and in 1715 as one of the lords of trade. In 1716, being then in his 45th year, he married the countess of Warwick and took up his residence with her in Holland house. The union proved an unhappy one to Addison. The countess was proud and high-tempered, and made his home so uncomfortable that he was fain to take refuge at the clubs and taverns, where it is said he often drank immoderately. In 1717 he reached his highest political elevation, being made one of the principal secretaries of state. But his inability to grapple with details and to take rank as a parliamentary leader unfitted him for the office, and he resigned it in the following year. Thenceforth until his death he applied himself to the completion of a treatise on the evidences of Christianity which had been projected some years before. His principal writings in addition to

those already mentioned were the "Drummer," a comedy, an opera entitled "Rosamond," and the "Frecholder," a sort of political "Spectator." Scattered among his essays are also several devotional poems, exalted in tone and felicitous in diction, which are still included in every considerable collection of sacred poetry. Addison was a man of integrity and sincere piety, and by his amiability, his pleasant humor, and his varied conversational powers greatly endeared himself to his friends. To those not intimate with him, a natural shyness of manner, which he was never able to shake off, made him seem cold and reserved. He has been accused of slighting and even of depreciating the merits of men of equal ability with himself. His treatment, when at the height of political power, of his old friend and literary coadjutor Steele, was not generous, and he incurred the resentment of Pope, who attacked him in some memorably bitter lines. But the uniform tendency of his writings precludes the idea that he was to any considerable degree insincere or unjust to his contemporaries.

ADEL. See ADAL.

ADELAAR, Adelaer, or Adeler (the Eagle), a surname given, on account of his gallantry, to **COET SIVERTSEN**, born in Brevig, Norway, Dec. 16, 1622, died in Copenhagen, Nov. 5, 1675. He rose from the position of a common sailor, in which capacity he served from 1637 to 1642 in the Dutch navy, to the rank of admiral, first in the Venetian and afterward in the Danish service. During the wars of Venice against the Turks, Adelaar gave evidence of his daring spirit by fighting his way in 1654, with the ship to the command of which he had risen by his skill, through 67 Turkish galleys, sinking 15 of them with about 5,000 Turks on board, all of whom are said to have perished. For this exploit Venice conferred upon him the order of St. Mark, the title of lieutenant general of the admiralty, and a pension. In 1663, after returning for a short time to the Dutch navy, Adelaar accepted employment under the Danish government, and in 1675 became commander-in-chief of the fleet just about to act against Sweden. He died before it sailed.

ADELAIDE, a city and the capital of South Australia, about 6 m. from the E. shore of St. Vincent's gulf, and 515 m. N.W. of Melbourne; pop. (with Port Adelaide and Albert Town) about 30,000. It is divided by the river Torrens into N. and S. Adelaide, and surrounded by a semicircle of hills. The city was founded in 1836, and incorporated in 1842. It possesses several fine squares, streets, and churches, a chamber of commerce, an assay office, and a botanical garden with a conservatory. King William street is the central thoroughfare and Hindley street the chief business locality. It is united by railway with Port Adelaide, 6 m. N. W. of the city, through which passes most of the commerce of South Australia. There is a large export trade in cereals, wool, and minerals, especially copper.

A considerable amount of gold obtained from the mines discovered in 1852 is assayed at Adelaide. The export of wool exceeds 7,000,000 pounds annually. The annual shipment of fine copper is nearly 100,000 cwt. Since 1862 the greater part of the ore has been smelted in the colony. Adelaide has flouring mills, breweries, machine shops, brass and iron founderies, and manufactories of tobacco, soap, candles, earthenware, leather, and barilla. The total value of South Australian imports (including £93,392 bullion and specie) in 1869 was £2,754,770; of exports, £2,993,035; total tonnage of vessels, exclusive of coastwise, nearly 350,000. Most of this trade centres in Port Adelaide. Albert Town is a small village about 1 m. from the port. The public revenue of the city in 1869 was £773,351, and the expenditure £653,107. It is the seat of an Anglican and a Roman Catholic bishop.

ADELAIDE, Eugénie Louise, princess of Orleans, daughter of Louis Philippe Joseph, duke of Orleans, surnamed *Égalité*, born in Paris, Aug. 25, 1777, died there, Dec. 31, 1847. In 1791 she went to England. On her return, in November, 1792, she found herself proscribed as an *émigrée*, and fled into the Austrian Netherlands, then invaded by the French army of the north, putting herself under the protection of her brother, the young duke of Chartres, afterward King Louis Philippe, who commanded a division of that army. Her brother being soon compelled to take flight himself to escape the guillotine, she was conducted over to the Austrian advanced posts. She rejoined her brother after many perils in Schaffhausen, Switzerland, May 26, 1793, accompanied by her former governess, Mme. de Genlis. They next took refuge in a convent, but their money ran short, and she threw herself upon the protection of her aunt, the princess Conti, at Fribourg. Her aunt dared not receive her in her own house, as the prejudice against the name of Orleans was so strong among the royal family of France, but she put her and Mme. de Genlis to board in a Swiss convent. After a separation of 10 years she saw her brother once more at Figueras in Spain; and after some further removals she at length rejoined him at Portsmouth, England, whence she followed him to Palermo, where in 1809 he married the daughter of the king of the Two Sicilies. From that time till the restoration she lived with him in Sicily. When Louis XVIII. had to quit France once more, she again followed her brother abroad. After the revolution of July, 1830, she persuaded him to accept the throne. Madame Adelaide, as she was now called, exercised considerable influence on the decisions of the king of the French, and was popularly regarded as his guardian angel. She died two months before his overthrow in February, 1848.

ADELAIDE, Saint, queen of Italy and empress of Germany, born in France in 933, died at

Seltz, Alsace, Dec. 16, 999. She was a daughter of Rudolph II., king of Burgundy, whose contest with King Hugo of Italy was peaceably ended by her marrying in 947 the latter's son, Lothaire II., after whose violent death in 950 she was imprisoned by his successor Berenger II. for declining to marry his deformed son Adalbert. She escaped to the castle of a relative and solicited the protection of Otho I., the Great, who, captivated by her beauty and character, married her in 951. She was crowned empress of the West in 962, and exerted much influence in Germany during a part of the reign of her son Otho II. and as regent during the minority of her grandson Otho III. She was called the "mother of kingdoms." The latter part of her life was consecrated to works of piety and charity at Seltz, where she founded a Benedictine monastery; and she is honored as a saint on Dec. 16. Her biography has been written by St. Odilon and others in Latin, French, and German, and by G. B. Semeria in Italian (*Vita politico-religiosa di Santa Adelaide, regina d'Italia ed imperatrice del sacro Romano imperio*, Turin, 1842).

ADELSBERG, a small market town of Carniola, Austria, on the Semmering railroad, midway between Laybach and Trieste, near a celebrated cavern, which has five main divisions. The first, called Neptune or Great Dome grotto, traversed for the length of 400 feet by the Poik river, and rich in stalactites, constitutes the old part of the cavern, which has been known for upward of 600 years. The entrance to the new parts of the cavern was accidentally discovered in 1816. This leads in the first instance to the second main division, called the emperor Ferdinand's chamber, with large corridors called the ball-room and the circus, where annual festivals take place, and that of Calvary, a mound formed by the ruined columns of rocks more than 200 feet high. The third main division consists of two basins of water called the dropping well and Tartarus. The fourth main division, the archduke John grotto, opens behind a curtain of transparent spar, and contains other shapes called Little Curtain and Gothic Hall. The fifth main division, the Francis Joseph and Elizabeth grotto, explored for the first time in 1857, discloses a range of chambers with brilliant and fantastic shapes, and a picturesque elevation called Little Calvary. About three miles from Adelsberg is the Black or Magdalen grotto, through which runs a river. Here was first discovered the *protus anguinus*, an animal half fish, half lizard, and eyeless. The Poik cavern, a mile from the last-named grotto, is only accessible by the aid of a rope, and remarkable chiefly for the dashing of the river over the rocks.

ADELUNG. I. **Johann Christoph**, a German lexicographer, born at Spantekow, Pomerania, Aug. 8, 1792, died in Dresden, Sept. 10, 1806. He finished his studies at the university of

Halle, and went to Leipsic, supporting himself by translations of valuable foreign works. His *Glossarium manuale ad Scriptores medie et infimae Latinitatis* (Halle, 1772-'84) is his most important achievement in this department. His great work, for which he took Johnson's English dictionary as a pattern, is his *Grammatisch-kritisches Wörterbuch der hochdeutschen Mundart* (Leipsic, 1774-'86). He also produced *Deutsche Sprachlehre für Schulen* (Berlin, 1781), and *Umständliches Lehrgebäude der deutschen Sprache* (Berlin, 1782). In 1787 Adelung was called to Dresden, and appointed head librarian in the electoral library in that city, where he conceived the plan of his *Mithridates*, a work which was to contain an account of all the known languages of the earth, with a translation of the Lord's prayer given as a specimen of each. He only lived to finish the first volume, which gave an account of the Asiatic languages. The work was afterward taken up by Johann Severin Vater, and his own nephew Friedrich Adelung, and finished in 4 vols. It is said that he devoted 14 hours a day to study.

II. Friedrich von, nephew of the preceding, born in Stettin, Feb. 25, 1768, died in St. Petersburg, Jan. 30, 1843. He began his career as a private tutor, and spent several years in Rome, but subsequently went to St. Petersburg, where he was appointed by the emperor Alexander preceptor of his brothers Nicholas (afterward czar) and Michael. His principal works are: "The Relations between the Sanscrit and Russian Languages" (1815), an "Essay on the Sanscrit Literature and Language" (1830), and *Bibliotheca Sanscrita* (1837).

ADEN (anc. *Adane*, *Attane*, or *Arabia Felix*), a fortified British seaport town on the S. coast of Arabia and on the gulf of Aden, about 120 m. E. of the entrance to the Red sea at Bab-el-Mandeb, lat. 12° 47' N., lon. 45° 9' E.; pop. about 50,000. It is built on the N. E. end of the peninsula of Aden, and connected with the mainland by a low, sandy isthmus. The latter, united with another peninsula called Jebel Hassan, forms the two extensive harbors of Aden, the best on the Arabian coast. The town stands at the E. base of a volcanic mountain range from 1,000 to 1,800 feet high. It is a place of considerable strength and is well garrisoned, its situation between Asia and Africa resembling that of Gibraltar between Europe and Africa. The superiority of the port and abundant supply of water render Aden a valuable and important station on the way from India to Europe. The inhabitants are Asiatic and African, with a few Europeans, chiefly English. The English political resident is the governing authority. The town is surrounded with gardens and fruit trees. The climate, though dry and hot, is not insalubrious.—In ancient times, Aden was the great centre of trade between Arabia, Egypt, and India. It was destroyed by the Romans in the time of Augustus, but soon revived. Marco

Polo speaks of its wealth and splendor in the middle ages. At the beginning of the 16th century it was so strongly fortified that the Portuguese failed to capture it; but the Turkish domination, from about 1540 to 1630, was injurious; and the imam of Sana and the sultan of Yemen, who successively ruled Aden for the next three generations, completed the work of the Turks, and left the place a heap of ruins in 1705, when it became independent. In 1838 Capt. Haynes proposed to the sultan of Aden to cede the town to Great Britain, and on his declining the English took forcible possession, Jan. 11, 1839. Since that time the town has gained commercial importance. In 1870 the imports from Great Britain amounted to £110,403, and the exports to £2,633.

ADERNO (anc. *Adranum*), a town of Sicily, in the government and 17 m. N. W. of Catania; pop. in 1861, 12,877. It is situated on a plateau at the S. W. foot of Mt. Etna, and is approached by a steep winding road of 4 m. A large proportion of the inhabitants are monks and nuns. There are many remains of the ancient town and ruins of mediæval buildings; and in the piazza is a Norman castle, now used as a prison.

ADET, *Pierre Auguste*, a French chemist and politician, born at Nevers in 1763, died about 1832. He was sent by the directory in 1795 to the United States as minister plenipotentiary, and presented to congress a tricolor flag on behalf of the French nation. On Oct. 27, 1796, he delivered to the secretary of state the celebrated decree of the directory complaining that the American government, in its treaty with England, had violated its neutrality and broken the treaty of 1778, and authorizing French ships of war to treat neutral vessels in the same manner that they allowed themselves to be treated by the English. After the delivery of this note Adet announced that he should suspend his functions, and he accordingly returned to France, after issuing an inflammatory address to the people of the United States. He subsequently adhered to Napoleon, but his political career remained unimportant. He composed a new system of chemical signs, but it found no favor.

ADHESION (Lat. *ad*, to, and *hære*, to stick), the force by which the particles of different bodies stick together, distinguished from cohesion, which is the force that holds the molecules of the same body together. There are six kinds of adhesion: solids to solids, liquids to solids, liquids to liquids, gases to solids, gases to liquids, and gases to gases. 1. *Solids to solids*. Two glass or metal plates with well ground surfaces, when pressed together, will adhere with such force that the upper one will not only support the lower, but an additional weight will be required to separate them. The amount of this adhesive force has been measured by recording the weights necessary for their separation. The records of the old experimenters on this subject are worthless, because they placed a lubricating fluid, oil or

fat, between the plates; they found thus the cohesion of the oil or fat, and not the adhesion of the plates. In later times Preechl in Germany has made the most careful experiments in this line; he took polished metal plates of $1\frac{1}{2}$ inch diameter, suspended the upper one to a balance, brought it to an equilibrium in a horizontal position, and attached the lower plate to a support underneath it. Both plates were then brought in contact, so that the flat polished surfaces covered one another perfectly, and the weights required in the scale at the other end of the balance beam to separate the plates were the measures of the adhesion.

Preechl's Adhesion Balance.

He found thus the following remarkable law: The adhesion between two plates of the same material is the same as that between one of the plates and any material which possesses a less adhesive force. For instance, to separate two copper plates required a weight of 21 grains; but the same weight was required to separate one of the copper plates from a plate of bismuth, zinc, tin, lead, &c., notwithstanding the adhesive force of bismuth to bismuth, zinc to zinc, &c., was found to be smaller than that of copper to copper. Preechl found also that an attraction of the plates manifested itself at an appreciable distance before actual contact, and he even measured the amount of this attraction at the distance of $\frac{1}{4}$ of an inch by means of weights in fractions of grains. The suspended plate when brought within this distance was attracted with an accelerated motion till the contact took place with a slight concussion. The idea that the pressure of the air was the chief cause of the adhesion of two such plates, as it is in the case of the well known experiment with the Magdeburg hemispheres, was set at rest by Boyle, who suspended the adhesive plates charged with weight in the vacuum of an air pump; the plates were not separated, while the hemispheres held together by the vacuum alone fell apart. The adhesion of solids to solids is also seen in the dust, which will not only adhere to perpendicular but even to inverted surfaces. Granite consists of feldspar, quartz, and mica, kept together by adhesion. A portion of such apparently adhesive force is, however, cohesion. For instance,

brick and mortar adhere chiefly by the cohesion of the mortar, which penetrates the pores of the brick; stones without sensible pores do not adhere so well to mortar. 2. *Liquids to solids.* Taylor was the first who investigated this subject in a scientific manner. He suspended a polished plate on the balance as above described, and brought it carefully down on the surface of a liquid, when it adhered, and the adhesion was measured by the weight required to separate the plate. After this method Guyton de Morveau in Paris found that plates of a French inch in diameter had the following adhesive power to mercury: gold, 446 grains; silver, 429; tin, 418; lead, 397; bismuth, 372; zinc, 204; copper, 142; antimony, 126; iron, 115; cobalt, 8; cold platinum, 108; red-hot platinum, 10 grains. Taylor also believed that the pressure of the air was the main cause, but Guyton found nearly the same results in the vacuum of the air pump. Link took a polished plate of agate of nearly one inch diameter, and tested its adhesion to different liquids; he found for water, 25 grains; sulphuric acid, 29; hydrochloric acid, 25; solution of saltpetre, 23; of lime, 21; almond oil, 16; petroleum, 16; turpentine and alcohol, 15; ether, 10. Where in many of these experiments drops of the liquid adhere to the plate used, it proves that the adhesion of the liquid to the solid is stronger than the cohesion of the liquid itself, and that the numbers obtained express rather the cohesion of particles of the liquid which were separated by the weight, than the adhesion of the plate to the liquid. The ascent of liquids in capillary tubes is also a result of adhesion, as well as the spreading out of liquids between two surfaces kept in close proximity. The chain pump, in which the water is carried up by a simple chain in a tube, is a practical application of adhesion. Prévost made interesting experiments on elective adhesion, showing how one fluid will drive another away from a surface for which it has more adhesion. He found that they displace one another in the following order: ether, alcohol, oil of bergamot, poppy oil, olive oil, nut oil, and other oils, water. Pure water displaces in its turn solutions of salts and alkaline earths. Camphor drives a film of water away from a surface, and pieces of camphor placed on water will show a peculiar motion; the same is seen with camphor or phosphorus placed on pure mercury. These phenomena are due to the evaporation of the solid and the cohesion of its vapor. We see practical applications of the adhesion of liquids to solids in writing, painting, printing, dyeing, washing, and elutriation, or separation of coarse from fine powders by suspension and settling in a large quantity of water. 3. *Liquids to liquids.* If a drop of water is placed on mercury, or a drop of oil placed on water, it does not keep its round form, but spreads out at once, because its adhesion to the liquid surface is greater than the cohesion of its particles. A drop of water on an oily surface, however, will not spread out,

as the cohesion of its particles is greater than its adhesion to the oil. The manner of displacement of one liquid by another having greater adhesive force to the liquid they float on, gives rise to a series of phenomena, for the study and exhibition of which Prof. Morton of the Stevens institute at Hoboken has recently contrived an apparatus in the style of a magic lantern. 4. *Gases to solids.* Many solids have the property of condensing gases on their surface (see ABSORPTION OF GASES), and polished metallic surfaces, even when long exposed to the air, will be covered with such a gaseous film, which is the first manifestation of chemical affinity. In the process of daguerreotyping, the polished silver plate will be inert unless this film of air has been removed by a polishing process just before the operation. Such removal of air may be made visible on the surface of a glass mirror which has not been rubbed for some time, by drawing a few figures or letters on it with a clean finger; the invisible change of surface will become visible by breathing on the glass, when the appearance of the deposit of watery vapor will show where the air film has been removed by friction. The adhesion of gases to solids is further illustrated by the small air bubbles which are often visible in mineral waters and effervescent drinks, sticking to the sides of the glass vessel in which they are contained, and not rising to the surface notwithstanding they are some 600 times lighter than the liquid. This adhesion is also illustrated by heavy powders and even sewing needles floating on water; the air adhering around the needle prevents the adhesion of the water, and the latter by its own cohesion forms a hollow depression in which the needle floats. The same adhesion of air around a piece of solid iron causes it to float on melted iron, notwithstanding it has not a less specific gravity than the fluid material. The mutual adhesion of solids and gases is also illustrated by the floating of particles of dust in the air; subdivision of matter increasing the surface, a continued subdivision will at last cause a point to be reached where the surface adhesion overcomes gravitation. In the vacuum of the air pump the dust falls down like a heavy body. It is the same with smoke, as this consists of solid particles carried upward by a current of heated air; the white smoke evolved by the burning of magnesium, zinc, or phosphorus illustrates this point very plainly. 5. *Gases to liquids.* The adhesion of gases to the surface of liquids is stronger in proportion to their solubility or absorption by the liquid. So carbonic acid adheres to water with greater force than air; but air possesses very strong adhesion to water, as shown by the currents of air carried down by any considerable cataract. Use is made of this adhesion in the so-called water bellows, in which a stream of water falling through a wide tube carries air downward and produces a blast so strong that this principle was used for driving the drills during the boring of the Mont

Cenis tunnel. In the so-called atomizer a current of air is used to divide water into a fine spray. In the Giffard injector a blast of steam is used to carry water by its adhesion to it into the boiler against its own pressure. The adhesion of air to water is further illustrated by the friction of a strong wind on its surface, which not only pushes it forward, but creates the waves. If oil is spread over the water, the air finds a surface for which it has little adhesion, and glides easily over it. This is the cause of the quieting influence of oil upon ocean waves, of which advantage has occasionally been taken in a storm by vessels having oil on board; the oil will spread at once over a large surface. The peculiar motions of camphor on water, phosphorus on mercury, &c., belong to the same class of phenomena; it is the elective affinity of the vapors of these volatile substances for the liquid on which they float, which is the cause of a strong and unequal evaporation at the points in contact, the evolving gas or vapor pushing the floating solid onward by its mechanical reaction. When the water is touched with a substance containing the merest trace of oil or grease, the motion of the camphor stops at once, as the water becomes then at once covered with a very thin but strongly adhering oil film, which has no affinity for the vapor of the camphor. A similar action is seen as soon as mercury is covered with a film of phosphorus; removing this film with the edge of a knife, the motion recommences at once, and is visible in the dark. The mutual adhesion of liquids and gases is also illustrated by the floating of watery particles in the atmosphere, as is seen in clouds and fogs. Watery vapor, present in the air in an invisible condition, becomes visible as soon as condensation commences, when a kind of fine water dust is formed, identical with the spray of large cataracts, where it originates by mechanical means. These watery particles are kept floating simply by their adhesion to the air, the total surface being very large compared with the total weight; but when the particles, by contact and mutual adhesion, form larger bodies, the total surface diminishes in proportion to the weight, while finally their gravitation becomes greater than their adhesion, and they fall down like rain. This falling down of water dust not only takes place in a vacuum, but even a trifling diminution in the atmospheric pressure will cause it when the amount of watery vapor in the air is large, as seen in the fact that rain is usually preceded by a descent of the mercurial column of the barometer. A descent of temperature is also a cause of this condensation of watery vapor, as it diminishes the capacity of the air for holding it. This adhesion theory makes the hypothesis of De Saussure quite unnecessary. This savant imagined that the particles of watery vapor were supported in the clouds by being hollow, with a vacuum inside, and thus, being lighter than the same volume of air, they were sup-

ported like a balloon. He was strengthened in this notion by the microscopic illusion which often causes solid small spheres to appear as if hollow. Still such hollow spheres are occasionally seen like microscopic soap bubbles, but they have air inside, are heavier than the air, and are only supported by adhesion. 6. *Gases to gases.* The interpenetration of gases being very great, it is impossible to keep their surfaces distinct; there must consequently be much adhesion and friction between them. Direct experiment with two gases cannot well be made, but observation demonstrates this great adhesion and friction. So one small jet of air in a wide tube will cause a rush of air to follow; the exhaust steam blown upward in the locomotive flue causes the air to rush out with it, and so creates the draft necessary to keep up a sufficient heat. This adhesion of gases plays no doubt a most important part in the actions of the atmosphere in the economy of nature.

ADIGE (anc. *Athesis*; Ger. *Etsch*), a river of the Tyrol and N. Italy, rises in the Swiss Alps, and flows E., S., S. E., and again E. about 220 m. to the Adriatic, S. of Chioggia. On its banks are the towns of Trent and Roveredo in the Tyrol, and the fortresses of Verona and Legnago in Venetia.

ADIPOCERE (Lat. *adeps*, fat, and *cera*, wax, from its fatty origin and waxy consistency), a white, solid, non-putrescible substance, into which human bodies are sometimes converted after burial. If the dead body be left exposed to the air at a moderate temperature, it undergoes the process of putrefaction, and is rapidly decomposed with the evolution of offensive and putrefactive gases. If buried in closed coffins with a limited supply of air, or in a tolerably dry soil, the process is somewhat modified; the putrescent character of the changes is less marked, the offensive effluvia are much less abundantly developed or are absorbed by the soil, and the body slowly decomposes, losing its original form and structure, and finally crumbling away to powder, leaving only the bones, which remain for a long time after the remainder of the body has become unrecognizable. But occasionally it has been found that bodies disinterred after the lapse of many years have not undergone either of these changes, but on the contrary have been converted into a white, solid, and very heavy substance, of firm consistency, retaining the original size and contour of the frame, so that the features may still be distinguishable, and even the natural markings and texture of the skin distinctly apparent. This substance is adipocere. It does not putrefy, but has evidently remained unchanged for a long time while buried, and after disinterment continues with but slight alteration. After exposure to the air it simply becomes lighter in weight, drier and more granular, owing to the evaporation of the water which it contained; so that a body which has undergone this conversion may be

afterward preserved for an indefinite time without changing materially in form or appearance. It is this change, or conversion of the soft parts into adipocere, which gives rise to the instances occasionally reported of human bodies being found after some years in a state of so-called petrification. The white color, solidity, and weight of the bodies thus found naturally suggest to the popular mind the idea of their having become petrified; but the change which they have undergone is in reality a very different one, and has little or nothing in common with a true petrification.—It is found that, for a body to become changed into adipocere, two principal conditions are mainly requisite. First, the body at the time of its burial must be fat. Lean bodies, as a rule, do not undergo the change in question, but only those which are abundantly supplied with adipose tissue. And yet it is not the adipose tissue itself which is converted into adipocere; it merely supplies some of the necessary elements, which are employed in effecting the alteration in other tissues. The second necessary condition is that the body should be buried in a moist place, and one in which the water collects in considerable quantity and remains standing at or about the level of the coffin, without being rapidly changed. Thus a single body, buried in marshy ground, or even deposited in a tomb which is undrained and collects standing water, will sometimes be found to have undergone the alteration. A collection of many bodies in or near the same spot seems also to favor the change. The first notable instance in which it was observed was on the removal in 1787 of the bodies deposited in the *Cimetière des Innocents* in Paris, where they had been accumulating for eight or nine centuries, many of them being found in the condition of adipocere. In 1849, in the city of New York, an old potter's field burying ground, situated at the junction of Forty-ninth street and Fourth avenue, was demolished and the bodies removed. Many of them had been buried in trenches or pits, in which the coffins were piled one upon the other, sometimes six or seven deep. This was said to have been done during the cholera epidemic of 1832. On removal of the bodies, those occupying the upper and middle tiers were found to be nearly or altogether decomposed; those forming the one or two lowermost tiers, beneath the level of the water retained by the soil, had apparently been converted into adipocere, but had been subsequently in great part dissolved and disintegrated by the water; while those situated between the two were in many instances also converted into adipocere, but completely preserved, retaining, with but a few changes, their natural form and size.—The process of the conversion of a human body into adipocere under such circumstances appears to be the following: The fatty substance of the adipose tissue first undergoes a change, by which it becomes rancid and produces two fatty acids, the oleic and the margaric acids.

These acids are liquid, and, being in large quantity, penetrate the neighboring tissues, so that the skin, muscles, &c., become permeated and saturated with them. At the same time, the albuminous matter of these tissues, beginning to undergo decomposition, produces a small quantity of ammonia, which unites with the fatty acids, making an ammoniacal soap. The greater part of these acids, however, is taken up by combinations of lime, forming an oleate or margarate of lime, substances comparatively insoluble and non-putrescible. The lime is derived partly from the soil, being brought down in solution by the rain water as it filters through successive layers of superincumbent earth. If other bodies are piled above, the water which filters through also brings the products of their decomposition and partial solution, among which are ammonia and lime, until the whole of the fatty acids of the bodies lying at the requisite level have combined with these bases, and have become in this way converted into adipocere. Thus the tissues, already permeated by the fatty acids, are now saturated with their ammoniacal and calcareous combinations, and especially with the oleate and margarate of lime, which protects them from further decomposition, and causes even their minute anatomical structure to be indefinitely preserved. These bodies when first taken out are, as we have said, dense and heavy, owing to the abundant moisture which they contain; but this soon evaporates after exposure to the air, leaving them comparatively light and dry.—It is not by any means all the tissues and organs of the body which are converted into adipocere, even under favorable circumstances. The adipose tissue itself disappears more or less completely, since its principal ingredient is used up in accomplishing the alteration of other parts. The internal organs generally, such as the heart, lungs, brain, liver, spleen, kidneys, &c., become shrivelled and disintegrated and finally undistinguishable. But the skin, fascia, tendons, fibrous membranes generally, and especially the muscles of the head, limbs, and trunk, are all more or less completely preserved. The muscular texture is easily recognizable by the naked eye, and the natural folds of the skin, or accidental impressions made upon the surface by portions of the dress or ligatures, may be plainly discernible after the lapse of many years. The bones, teeth, hair, and other less destructible parts of the body, do not seem to be particularly influenced by the change, but undergo only the usual very slow and almost imperceptible alterations which they would present in ordinary cases.

ADIPOSE SUBSTANCES (Lat. *adeps*, fat), a class of substances of a fatty nature, which are present in greater or smaller quantity in most animal and vegetable organisms. Adipose substances are all composed of carbon, hydrogen, and oxygen, to the exclusion of other chemical elements. They are all crystallizable at a low temperature and fluid at a high temperature,

combustible, and insoluble in water, but soluble in ether and in each other. They differ from each other in the exact proportion of the different chemical elements which they contain, and particularly in the precise degree of temperature at which they crystallize or assume the solid form; some of them, such as stearine when pure, remaining solid above 140° F., while others, such as oleine, continue fluid until near the freezing point of water. The three special kinds of adipose substance with which we are most familiar are stearine, margarine, and oleine; stearine and margarine being the principal constituents of the more solid fats, while oleine is abundant in the more fluid fats, or oils. In the animal body, these different substances are usually mingled with each other in various proportions, thus forming fats or oleaginous ingredients of different degrees of consistency. They are found in the adipose tissue, of which they form by far the largest part; in the minute cells of the liver and of some cartilages, where they are deposited in the form of microscopic globules; in the brain and nervous matter, where they are found in the proportion of from 5 to 15 per cent.; in the marrow of the bones; in the chyle, to which fluid they impart its opacity and white milky color; and in the milk itself they exist under the form of the milk globules, which are minute particles of butter, formed of a mixture of various fatty substances, and suspended in the serous fluids of the secretion. There is also a sebaceous matter secreted by the skin, especially in the parts covered with hair, which is a semi-solid or lardaceous secretion, consisting largely of adipose materials. Fatty substances also exist in considerable abundance in the food, since they enter so largely into the composition of animal and vegetable tissues. The fat of meat, the liver and the brain of animals, when used as food, of course supply a large quantity of adipose substances. Milk and butter and the yolk of eggs are especially rich in these materials; and many articles of vegetable food, such as nuts, olives, Indian corn, &c., also contain them in large proportion.—Although fatty substances by themselves are not capable of sustaining life when used exclusively as articles of food, yet they are extremely useful and perhaps indispensable as part of the regimen. This is shown by the instinctive desire, which is nearly universal among healthy persons, to have some kinds of adipose materials as a portion of the food: butter, fat, and olive oil being the kinds most highly valued and abundantly used. It has also been proved directly by the experiments on the fattening of animals by Bous-singault (*Chimie agricole*), who found that, however abundant and appropriate the other elements of the food might be, the addition of a small quantity of fatty substance improved greatly the condition of the animals, and caused the formation in their own bodies of a much larger amount of fat than that which had been

introduced. Thus the fat which exists in the interior of the body of a living animal has not all been derived from similar materials taken with the food. On the contrary, there is every reason to believe that fatty substances are produced in some way, in the process of digestion and assimilation, from the starchy and saccharine elements of the food. It is a matter of common observation that food containing an abundance of starch and sugar is especially favorable to the deposit of fat; and Bous-singault also found that the most effective diet for the fattening of pigs was one consisting very largely of cooked starchy materials, with the addition of a small proportion of fatty substances. The adipose substances found in the body are thus partly introduced with the food, and partly generated from the transformation of its starchy and saccharine ingredients. They are then deposited in the various tissues, or form for the time a part of the fluids or secretions, like the chyle, the milk, and the sebaceous matter of the skin. Of all the fatty material thus taken with the food, or generated in the system, but a small part is again discharged in its own form. It is only the fat of the sebaceous matter and that of the milk which is thus discharged. The remainder is decomposed or transformed in some way in the daily process of nutrition, so that it is no longer recognizable as fat. In the opinion of some writers, it is directly oxidized by the air taken in by respiration; thus producing animal heat and the evolution of carbonic acid, as it would do if burned, as in the case of ordinary combustion. But this must be considered as doubtful, since we cannot yet follow all the details of the chemical changes which take place in the living body. It is certain, however, that the fat which is taken up from the intestine during the digestion of food is absorbed by the vessels, partly deposited in the adipose and other solid tissues, and for the most part rapidly decomposed or transformed, so that it disappears and is used up, so to speak, in the nutrition of the body.

ADIPOSE TISSUE, the tissue in animal bodies containing the largest proportion of adipose substance, known in ordinary language as the fat of the animal, in distinction from the lean or muscular flesh. The adipose tissue is situated principally beneath the skin and over the muscles, particularly those of the abdomen, about the cheeks, in the orbit of the eye, over the buttocks, on the outside of the heart about the origin of the great vessels, over the intestines, where it forms a special layer or distinct curtain called the *omentum*, around the kidneys, and in various places about the inner side of the abdominal walls. It consists of a number of distinct masses or lobules, which are connected with each other by thin layers of areolar tissue, containing the few blood vessels and nerves with which the adipose tissue is supplied. Each lobule in its turn consists of a number of transparent vesicles, or closed sacs, about $\frac{1}{100}$ of an inch in diameter, which are

peculiar to the tissue and are called the adipose vesicles. Each vesicle consists of a thin, colorless, and structureless animal membrane, embracing a closed cavity, and filled with fluid or semi-fluid fat. The vesicles generally approximate a globular or ovoid form, but with some flattening and angularity of surface produced by mutual compression. The albuminoid elements entering into the composition of the adipose tissue, such as those composing the wall of the vesicles, the intermediate areolar tissue, &c., are much less abundant than its fatty contents. The blood vessels and nerves are particularly scanty, as compared with those of the neighboring skin and muscles; so that a wound of the adipose tissue produces but slight pain and very little bleeding.—The functions of the adipose tissue are for the most part physical in their character. It acts as a cushion to protect delicate parts from pressure or injury. Particularly, wherever the skin is exposed to frequent pressure over a bony prominence, as over the buttocks or beneath the heel, it is defended by an elastic layer of fat. The eyeball rests in its socket upon such a cushion of adipose tissue, and the abdominal organs are protected from injurious pressure by that of the omentum and the abdominal walls. The entire layer of adipose tissue beneath the skin

and elsewhere also acts as a protection to the animal warmth. Being to a great extent a non-conductor, it is a kind of natural blanket, which prevents the dissipation of the heat of the internal organs, and thus serves to maintain their temperature. An abundant layer of adipose tissue is accordingly an effective protection against external cold, while animals which are in an emaciated condition more readily suffer from its effects.—Adipose tissue is sometimes deposited in an excessive degree, forming morbid growths or tumors. These tumors, however, are usually not dangerous, but only inconvenient from their size or situation.

ADIRONDACK MOUNTAINS, the principal group of mountains in New York, extending from the extreme N. E. corner of the state in a S. S. W. direction toward its centre, occupying portions of Clinton, Essex, Franklin, and Hamilton counties. The Catskills, S. of the Mohawk river, may be regarded as their extension in this direction. In the western part of Essex county these mountains have their greatest development, and present the highest peaks of any of the northern spurs of the Appalachian chain, Mount Washington in New Hampshire alone excepted. They rise from an elevated plateau, which extends over this portion of the country for 150 miles in latitude and

Longitude East 3 from Washington

Longitude West 74 from Greenwich

100 in longitude, and is itself nearly 2,000 feet above the level of the sea. The highest summits are those of Mounts Marey, St. Anthony, McMartin, Seward, Emmons, and McIntyre. The first of these reaches the height of 5,337 feet above the level of the sea. St. Anthony, McMartin, and Seward are supposed to be about 5,000 feet high, and the other two summits about 4,000 feet each. These mountains are in ranges, which have a general N. N. E. and S. S. W. direction; but being formed not of stratified, but of granitic rocks, they lack that precision of outline which characterizes the mountains of the same Appalachian system in the middle and southern states. For the same reason the peaks assume more of the conical form, the slopes of the mountains are more abrupt, and the scenery wilder and grander than among the mountains of the sedi-

mentary rocks. The Saranac and the Ausable, whose sources are among these mountains, run in nearly parallel lines toward the northeast, discharging their waters into Lake Champlain. They define upon the map the position of the valleys, which have the same general arrangement throughout the whole chain, and to some extent the position of the ranges of mountains also. In the other direction, the Boreas, the Hudson, and the Cedar rivers, which all unite below into the Hudson, define the extension of the valleys of the Ausable and its branches on the S. declivity of the great plateau; and further west the chain of lakes, including Long lake, Raquette lake, and the Fulton lakes, lie in the same line with the valley of the Saranac, and mark its extension from the central elevation of the plateau toward the southwest. The drainage of this table land is toward Lake

The Adirondacks from Placid Lake.

Champlain on the east, the St. Lawrence on the northwest, and the Hudson on the south. The sources of many of the streams which flow in these different directions often interlock with each other; and the numerous lakes and ponds with which they connect lie almost upon the same horizontal plane. The elevations of many of these sheets of water are given by Prof. Benedict, and nearly all of them are included between 1,500 and 1,731 feet above the level of the sea, the latter being the elevation of Raquette lake. The great numbers of these lakes and rivers easily navigable to the light canoe of the Indian, with occasional portages past the rapids and falls, gave to this district in former times features of great interest. The deer, moose, caribou, bear, beaver, and otter were abundant throughout this region, and, with the numerous varieties

of fish, among them the salmon trout and the pike, of those excellent qualities only met with in our northern inland waters, gave to that ancient race nearly all they required for sustenance. The game, excepting the caribou, still linger about the Adirondacks. The mountains are covered with forests, groves of birch, beech, maple, and ash succeeding to the evergreens, among which the most common are the hemlock, spruce, fir, and cedar, with the valuable white pine intermixed with and overtopping the rest. In the lower lands along the streams a denser growth of the evergreens is more common, forming almost impenetrable swamps of cedar, tamarack or hackmatack, and hemlock. The white pine is the most valuable product of this region; and the numerous rivers, which served as roads for reaching every part of it, now answer the same purpose

for conveying this valuable timber to market. So important has the pine upon these mountains become, that large sums have been expended in removing the obstructions of the streams, and in opening new outlets to the lakes, by which in the spring freshets the logs could be run down. As may well be supposed, this mountain region offers little inducement to the permanent settler. Only along the wider bottoms of the Saranac and the Ausable, the fertile alluvial soil, the wash of the mountains, tempts to cultivation.—About 40 years ago the discovery of enormous masses of magnetic iron ore in the very heart of the mountains led to the establishment of the village of Adirondack, in the township of Macomb, on the western border of Essex county, about 50 m. W. of Lake Champlain. Iron works were erected on a scale of considerable magnitude; but the final result was that the distance from market, the scarcity of labor, and the difficulties of transportation made the enterprise unprofitable in spite of the excellence and abundance of the iron, and the works are now wholly abandoned.—Of late years the whole northern wilderness of New York has come to be popularly known as the Adirondaeks, and is much resorted to, not only by sportsmen, but by tourists of both sexes, for whose accommodation taverns have been established at convenient distances. All travelling there is done by means of boats of small size and slight build, rowed by a single guide, and made so light that the craft can be lifted from the water and carried on the guide's shoulders from pond to pond or from stream to stream. Competent guides, steady, intelligent, and experienced men, can be hired at all the taverns, who will provide boats, tents, and everything requisite for a trip. Each traveller should have a guide and a boat to himself, and the cost of their maintenance in the woods is not more than a dollar a week for each man of the party. The fare is chiefly trout and venison, of which there is generally an abundance to be procured. A good-sized valise or carpet-bag will hold all the clothes that one person needs for a two months' trip. There are several routes by which the Adirondaeks can be reached, but the best and easiest from New York is that by Lake Champlain. The steamer from Whitehall will land the traveller at Port Kent, nearly opposite Burlington, Vt., where coaches are always waiting to take passengers, six miles, to Keeseville. Here conveyances for the wilderness can always be had.

ADIT (Lat. *aditus*, entrance), a horizontal passage made into mines for the purpose of draining them, and also for the extraction of their products at the lowest convenient level. In very mountainous regions adits often present the readiest means of access to the mineral veins known to exist in the interior of precipitous hills. Enormous sums have been expended in the silver region of Mexico in these exploring adits. One of the most fa-

mous adits in the world is that of Klausthal, in the Harz, which is $6\frac{1}{2}$ miles long, and passes upward of 300 yards below the church of Klausthal. Its excavation lasted from the year 1777 till 1800, and cost about \$330,000. The adit which drains the district of Gwenap, in Cornwall, is estimated with its branches to extend a distance of 30 miles; its mouth is in a valley near the sea, and from it are discharged the superficial waters of numerous mines, as also all the water pumped up in them to its level. One of the most extensive adits in the world was commenced in the beginning of the present century by the Austrian government, and is called by the name of Joseph II. Its mouth is in the banks of the river Gran, in Hungary, and it passes by the mines of Hodritz toward those of Schemnitz, about 10 miles. The object of its construction is partly to explore for new veins, and in part to drain mines already in operation. A work of similar magnitude has been undertaken in the Washoe mining district of Nevada, for the purpose of developing the Comstock lode. It is known as the Sutro tunnel, and the plan was to commence at the Carson river, 150 feet above the stream, and to excavate a space of 12 by 14 feet to a distance of 19,790 feet, when the lode would be cut at a depth of 1,898 feet below the outcrop. A cross tunnel was to be constructed along the ledge about 12,000 feet, to connect with all the mines, and four shafts were to be sunk for ventilation. A company for its construction received large privileges from congress in 1866, and afterward application was made for a government subsidy. A commission was appointed to examine the project, which early in 1872 reported unfavorably, estimating the cost at \$4,418,329. The work was not then far advanced, but has since been vigorously prosecuted both upon the main tunnel and the shafts.

ADJUTANT, a staff officer attached to the commander or to the headquarters of larger or smaller bodies of troops. Generally, the commander of every military post, battalion, regiment, brigade, division, corps, army, or military department has an adjutant, or an adjutant general, with such assistants as the importance of the command may require. The duty of the adjutant is to assist his chief in the performance of his military duties, to make known his orders, to see to their execution, to receive reports, and to take care of the records and returns pertaining to the troops. He has therefore under his charge, to a great extent, the internal economy of the command to which he is attached. By authority of the commander, he regulates the rotation of duty among its component parts, and gives out the daily orders; at the same time, he is a sort of clerk to his chief, carries on the correspondence with detachments and with the superior authorities, arranges the daily reports and returns into tabular form, and keeps the journal and statistical books of his body of troops. Larger bodies of troops now generally have a regular

staff attached, taken from the general staff of the army, and under a "chief of the staff," who takes to himself the higher functions of adjutant, and leaves him merely the transmission of orders and the regulation of the internal routine duty of the corps. Owing to the difference of regulations and military systems, as well as to the peculiarities of commanders, there is practically a great variety in the functions of adjutants. In the army of the United States there is one adjutant, or adjutant general, attached to the war department, who issues the orders of the secretary of war and the general-in-chief, and has charge of the military record of the government. He is also head of the adjutant general's department, composed of a fixed number of colonels, lieutenant colonels, and majors, promoted by selection from the officers of the army, and assigned to duty in the bureaus of the adjutant general's office or with the headquarters of armies, corps, divisions, brigades, or military divisions and departments; they are called assistant adjutants general. Besides these, the governor of each state has an adjutant general, while the requirements of monarchical institutions have created in almost all European states hosts of titular adjutants general to the monarch, whose functions are imaginary, except when called upon to do duty with their master; and even then these functions are of a purely formal kind.

ADJUTANT BIRD. See MARABOU.

ADLERBERG. I. Vladimir Fedorovitch, count, a Russian statesman, born in St. Petersburg in 1793. His mother, the widow of a colonel, and superior of a seminary for the daughters of the nobility, was much befriended by the empress Maria Feodorovna, through whose influence the son became a favorite at court, and in 1817 adjutant to the grand duke Nicholas. After the latter's accession to the throne, Adlerberg became his constant companion, and was made general of infantry in 1843 and count in 1847. In 1852 he was appointed minister of the court, the most influential office in the personal service of the imperial family, and which requires constant attendance on the emperor. After the death of Nicholas (1855), and at that emperor's urgent recommendation, he retained his post under Alexander II., whose full confidence he also enjoyed. In 1869 he retired on account of old age. For many years he had also officiated as postmaster general, and contributed much toward postal reform. His sister, widow of the councillor of state Baranoff, brought up the daughters of the emperor Nicholas, and was made a countess in 1846. II. Adlerberg II., Alexander, count, eldest son of the preceding, succeeded him in 1869 as minister of the court and chancellor of imperial decorations, and holds the rank of general of infantry and chief aide-de-camp of the czar. He is inseparable from the emperor, of whom he had been a schoolmate, and whom he accompanied on his journey to Germany and the

Caucasus in 1871. III. Adlerberg III., Nicholas, brother of the preceding, was active in the Hungarian campaign of 1849, published in 1852 a narrative of his journey to the Holy Land (*Ot Rima v' Yerusalem*, "From Rome to Jerusalem"), was governor of the province of Taurida in 1854-'5, and from 1857 was for some time military commissioner in connection with the Russian embassy at Berlin. He holds the rank of adjutant general of the emperor, and since 1861 also that of lieutenant general. He has been for several years governor general of Finland.

ADLERCREUTZ, Karl Johan, count, a Swedish soldier, born April 27, 1757, died Aug. 21, 1815. He distinguished himself in the Finnish war against Russia in 1808, as adjutant general of Field Marshal Klingsporr, and on March 13, 1809, joined that officer in arresting Gustavus IV. in his own palace. The king was deposed, and the diet on May 1 thanked Adlercreutz and his fellow conspirators for having saved Sweden from ruin by their daring. He was made lieutenant general in 1809 and count in 1814.

ADLERSPARRE. I. Georg, count, a Swedish soldier and statesman, born March 28, 1760, died Sept. 23, 1835. He enjoyed the confidence of Gustavus III., after whose death (1792) he retired from the army, and edited from 1797 to 1801 a periodical, *Läsning i blandade Ämnen*, the liberal politics of which gave umbrage to the government. In 1809 he joined in the campaign against Russia, as well as in the conspiracy which culminated on March 13 in the arrest and deposition of Gustavus IV. He had insisted upon the consummation of this event without bloodshed and revolutionary commotion. On May 1, 1809, he received the public thanks of the diet, and was promoted to various high dignities, eventually including that of count and provincial governor general, which latter post he resigned in 1824. He was fined in 1831 for having published secret state papers and his private personal correspondence with Swedish princes, but protested against the injustice of the punishment and persisted in the publication (*Handlingar rörande Sveriges äldre och nyare historia*, 9 vols., Stockholm, 1830-'33). II. Karl August, count, an author, eldest son of the preceding, born in 1810, died in 1862. Like his father, he possessed poetical talent, and published various novels and lyrical effusions under the name of Albano. His reputation rests on his historical works, entitled 1809 *Års Revolution*, and 1809 och 1810 *Tidstafvor* (respectively 2 and 3 vols., Stockholm, 1849), and *Anteckningar om bortgångna Samtida* (3 vols., 1860-'62).

ADMETUS, in Greek mythology, a king of Pheræ, in Thessaly, who took part in the Calydonian hunt and the Argonautic expedition. He is said to have obtained, through the intercession of Apollo, deliverance from death, on condition that his father, mother, or wife

should voluntarily die for him. This was cheerfully complied with by his wife Alcestis, daughter of Pelias, who was subsequently rescued from the hands of Pluto by Hercules and restored to Admetus.

ADMINISTRATOR. See EXECUTOR.

ADMIRAL, a naval officer of the highest rank. The title was introduced by the Genoese and other Italians into Europe, and was probably derived from the Arabic word *amir*, which was also used in reference to shipping by the Greeks of the lower empire. The office of admiral was not created for the navy of the United States until during the second year of the civil war. Previously the grade of captain was the highest in the service, although the title of commodore had been accorded to commanders of squadrons and naval stations, and they had assumed the commodore's distinguishing broad pennant. By act of congress, Jan. 16, 1857, captains in command of squadrons were denominated flag officers, and by subsequent and progressive departmental orders and regulations they substituted for the broad pennant a square blue flag worn at the mizzen; next the same at the fore for those over 20 years commissioned as captain, and the senior captain's was carried at the main; finally they came to arrogate all of the functions of admirals. Congress established the grade of rear admiral July 16, 1862, and commissioned therein on account of eminent individual services David G. Farragut and three other captains from the active list, and Charles Stewart and ten other distinguished veterans from the retired list. The grade of vice admiral was constituted by act of Dec. 21, 1864, and Farragut promoted thereto as a reward for Mobile; and as a further token of gratitude and honor the grade of admiral was created for him July 25, 1866. The rank of admiral is relatively equivalent to that of general in the army, vice admiral to lieutenant general, and rear admiral to major general. The pay per annum of admiral is \$13,000; the sea pay of vice admiral \$9,000, and of rear admiral \$6,000. There have been bestowed 2 commissions of admiral, 3 of vice admiral, and 55 of rear admiral; and there are now in the service 1 admiral, 1 vice admiral, and 38 rear admirals; of the latter, 12 are on the active and 26 on the retired list.—In Great Britain there were until 1864 three classes of admirals, red, white, and blue. The distinction of flags was then abolished, and only the white flag retained in the royal navy. The management and superintendence of the navy of England was formerly vested in a lord high admiral. James II, when duke of York held this office, and when king, on account of his predilection for the naval service, kept it in his own hands. Prince George of Denmark, husband of Queen Anne, was also lord high admiral. The last incumbent of the office was the duke of Clarence, afterward William IV., who held it from May, 1827, till September, 1828, since which time

the office has been put in commission, the duties being performed by the lords of the admiralty, who are six in number, the first lord having a seat in the cabinet. His pay is £4,500 per annum.—The highest officer in the Russian navy bears the title of general admiral.

ADMIRALTY. In England at a very early period the administration of the navy, and of all affairs pertaining to commerce, ships, and navigation, or connected in any way with the high seas or the navigable waters of the realm, seems to have been delegated to a naval officer of high dignity called the lord high admiral, deriving his authority directly from the sovereign, and invested with powers over some of the sovereign's most important prerogative rights. His functions, covering originally all maritime affairs, extended also to the private concerns of the subject in commercial trade. All of his powers which required judicial action were delegated to a court of admiralty, and they still remain its characteristic function. That part of the jurisdiction which was purely executive, and which related especially to the navy and the royal privilege, was at a very early date transferred to other departments or tribunals. Originally, then, the high court of admiralty in England was the court of the lord high admiral, and its judge was his lieutenant. The admiral also appointed vice admirals, and their lieutenants in turn were the judges of the vice admiralty courts in different parts of the kingdom. The commission usually issued to the admiral of England in the 16th and 17th centuries gave him cognizance of "debts, bills of exchange, policies of insurance, accounts, charter parties, contractions, bills of lading, and all other contracts which any ways concern moneys due for freight of ships, moneys lent to be paid beyond the sea at the hazard of the lender, and also of any cause, business, or injury whatsoever had or done on or upon or through the seas or public rivers, or fresh waters, streams, lavens, and places subject to overflowing, within the flowing and ebbing of the sea, upon their shores or banks, from the first bridges toward the sea, throughout our kingdom or dominions aforesaid, or elsewhere beyond the seas, or in any parts beyond the seas whatsoever," &c. A commission of the time of Henry VIII. gives to the admiral authority in cases of treasons, robberies, and other crimes on the seas or other waters within the king's maritime jurisdiction. But these commissions, though full and large, are, it must be remembered, of a comparatively recent date; for the admiralty jurisdiction is very ancient, and the "Black Book of the Admiralty," a sort of code of the admiralty law of England, compiled probably about the beginning of the 14th century, contains constitutions of John (1199), Richard I. (1189), and Henry I. (1100), relating to the admiralty. The jurisdiction of the court was modelled after that of the consular courts of the Mediterranean. Its decisions

were governed by the practice of those and the like courts on the continent by the ancient customary laws of the sea and commerce, and by those collections—such as the laws of Rhodes and Oléron, the *Waterrecht* of Wisby, the Hanseatic ordinances, and the *Consolato del Mare*—which from time to time shaped the admiralty law of Europe. From the course of the administration of the law in those continental courts from which the English admiralty borrowed its procedure, and from the fact that its characteristic jurisdiction related so largely to commercial dealings with the states of continental Europe where the Roman law prevailed, the law and practice of the English court adopted and followed also the principles and rules of that system of jurisprudence. But the Roman law was regarded in those early periods with great jealousy and suspicion in England, and many efforts were made to restrain the jurisdiction of the admiralty within the narrowest possible limit. It was charged in the reign of Edward III. that now the admiralty claimed jurisdiction of trespasses on land and within the bodies of counties, and undertook to regulate the wages of labor and the prices of provisions. As a result of the complaint it was enacted in the 13th year of Richard II. (1390), that “the admirals and their deputies shall not meddle henceforth of anything done within the realm, but only of a thing done upon the sea;” and in the 15th year of the same reign (1392), that “all manner of contracts, pleas, and queables, and all other things rising within the bodies of counties, as well by land as by water, as afore, and also wrecks of the sea, shall be determined and remedied by the laws of the land, and not before nor by the admiral nor his lieutenant in any wise.” The admonitions of these statutes were still further emphasized by a law of Henry IV. (1411), which not only inflicted fines on persons proceeding in the admiralty courts in the forbidden causes, but also fined the admiralty judges who entertained their suits. About the same time the common law courts began to issue their prohibitions to the courts of admiralty, forbidding their interference in certain disputed cases. This matter of prohibitions became the subject of a sort of convention between the judges of the rival courts early in the reign of Elizabeth (1575), which quelled the discord until the next reign. Coke (1551–1633) repudiated the agreement just referred to, though it had been observed for a quarter of a century, on the ground that it was not signed, and that the justices of the queen’s bench had never assented to it; and he accordingly sent out prohibitions from his court more fierce than had ever issued yet. There was never much peace with the admiralty courts during his time, and the common law courts had their own way. In 1632 certain ordinances were drawn up by the king and his council and the judges of the two courts, which were again favorable to the ad-

miralty. But these were set aside by the commonwealth, and in turn a new ordinance of that period (1648), still more favorable to the admiralty, was annulled at the restoration, and the common law judges began anew with their prohibitions. The jurisdiction of the court was now very much narrowed, and among the more important branches of it which were lost were cases of seamen’s wages, freight, charter parties, claims for the building, repairing, or supplying of ships, and questions involving disputes of title to ships. The statute 3 and 4 Victoria began to repair and restore the damaged capacity of the admiralty. That act extends the power of the court to all cases of salvage or damage, though arising within the body of a county; to questions of title in causes for possession; to cases of damages, bottomry, and wages; to suits for supplies furnished to foreign ships; and to the claims of mortgagees when the ship or her proceeds are under the control of the court. The so-called admiralty court act of 1854, the elaborate merchant shipping act of the same year, and especially and notably the admiralty court act of 1861, “to extend the jurisdiction and improve the practice” of the court, have increased very materially its power, and bear strong testimony to its usefulness in all matters of a maritime character.—The criminal jurisdiction of the English admiralty was anciently very extensive, and included all crimes and injuries committed on the high seas, and the general government of the navy. In later times, however, this branch of its jurisdiction was withdrawn. Cases arising in the public ships of the realm were transferred to naval courts martial by acts of Charles II. and George II.; and cases arising on ships of commerce or in foreign ports were assigned to certain commissioners and courts created by acts of 28 Henry VIII., 39 and 46 George III., and 4 and 5 William IV., in which tribunals the acts provide that the lord high admiral, or as now the judge of the admiralty, shall be included; and by the operation of still more recent statutes the criminal jurisdiction of the court is almost entirely annulled. Apart from the general, or as it is called the instance side of the court, it has exercised very important functions in time of war as a court of prize. This court is called into being by the special warrants of the crown at the outbreak of each war, and takes cognizance of all seizures of prizes and their condemnation, and all other matters relating to capture. (See PRIZE.)—In France admiralty courts existed prior to the revolution of 1790, and there as in England derived their authority from a lord high admiral. Their jurisdiction was even more extensive than that of the English courts, and included all questions of prize, salvage, bottomry, charter parties, average, wages of seamen, fisheries, and the building, fitting, manning, and sale of ships; and also all crimes or misdemeanors committed on the high seas, except those connected with the

navy. These courts were abolished in 1791, and their functions distributed to other tribunals. All commercial questions were assigned to the tribunals of commerce, matters of prizes to a special court called the council of prizes, and the criminal jurisdiction was transferred partly to courts of assize and partly to the correctional police.—In Ireland there also exists, unless very recent changes have been made, a high court of admiralty which is independent of that of England, and has a jurisdiction of the same character and quite as extensive. Such a court also existed in Scotland until it was abolished by statute of 1 William IV., ch. 69. Its jurisdiction on the instance side was transferred to other courts. Its authority in cases of prize and capture had been already, by 6 George IV., ch. 120, vested in the high court of admiralty of England.—The American admiralty exists under the clause of the constitution which declares that the judicial power shall extend to “all causes of admiralty and maritime jurisdiction,” and the statute vesting that power, which gives to the district courts exclusive original cognizance of all civil causes of that description. The interpretation of this clause of the constitution has brought out conflicting opinions as to its proper meaning. For upon the principles and rules of construction which are familiarly applied in determining what is the law of the United States in civil or criminal or equity cases, in the absence of specific legislation, the question fairly arises whether the admiralty and maritime jurisdiction contemplated by the constitution was the jurisdiction as it existed in England when the colonies declared their independence, or as it existed in the colonial courts at the time of the revolution, or as it was exercised by the states when the constitution was adopted; whether it was not rather that characteristic and proper jurisdiction of the English admiralty before it was taken away from it by prohibitions or encroachments; or whether finally the clause was not, in a still more liberal spirit, designed to embrace all causes relating to shipping and maritime commerce which, in the broadest sense and within the traditional functions of admiralty courts of full powers, are regarded as maritime and admiralty cases. Though no very definite test by which the extent of the jurisdiction is to be determined has been laid down, yet it is certain that the American jurisdiction does not depend absolutely on any of the criteria suggested by the propositions just recited, and that the clear tendency at least of our decisions is to extend the authority of the court over its ancient domain, without confining it within limits prescribed by any particular historical precedent. Our greatest judges, and eminently Marshall and Story, have construed the constitutional grant with the utmost liberality, and with the purpose of embracing within its scope the largest powers; and especially within the last 20 years the disposition of the supreme court has been to regard all causes of which foreign

admiralty courts have usually and characteristically taken cognizance, and which are historically known as admiralty and maritime causes, as being cases within the constitutional provision.—The first statute which drew upon the constitutional grant, and first actually vested its power in our courts, was the act of 1789, by which “exclusive original jurisdiction of civil causes of maritime and admiralty jurisdiction” was assigned to the district courts. This statute, it will be observed, repeats the language of the constitution, and therefore gives no aid to the definition of the power. But the extent of it has been illustrated by a multitude of adjudicated cases, and from these the general character and range of the authority can be easily gathered. The jurisdiction can be most conveniently considered under two aspects: first, as it is determined by the subject matter; and second, as it is determined by the locality. Upon what is probably the right ground of construction, the first of these is the proper criterion; for, as has already been intimated, the reason of the thing depends probably only upon the consideration whether the subject is of a maritime character or not. The early contests which arose in England upon the competency of the admiralty to interfere within the bodies of counties or other land lines have, however, fixed the criterion of locality so firmly that it has been constantly appealed to here; but it has been found singularly embarrassing in this country from the fact that so much of our commerce is carried on on great inland seas, and on great rivers which are navigable through the whole extent of our territory. The European states afford no parallel to these, and to adopt literally the limits of the jurisdiction fixed by the practice of their admiralty courts was to exclude the ships and commerce of all these waters. Nevertheless, the precedents of the foreign admiralty law in these respects were closely followed for fully half a century after the foundation of the government; and though our courts did not submit to the limited jurisdiction by which the English courts were restrained within headlands or the bodies of counties, yet they did hold regularly that no cause came within their power unless it arose within the movement of the tides. At last a case arose in the harbor of New Orleans. There the waters of the Mississippi flow always outward and never backward with the ocean tide; but upon proof that there was nevertheless a perceptible rise and fall of the water, caused by the tides below, it was held that this was sufficient, and that the jurisdiction attached. The decision was admitted to be a forced one, and the tide on which it rested was afterward spoken of in the supreme court rather contemptuously as “an occult tide without ebb or flow.” But there was good sense at the bottom of the decision, and the inconvenience of making tide waters the limit of the jurisdiction led to the enactment in 1845 of the famous act “extending the

jurisdiction of the district courts to certain cases upon the lakes and the navigable waters connecting the same." This act did not cover the great rivers which do not connect the lakes, nor did it profess to extend a real admiralty jurisdiction even over the waters to which it referred. It created rather a sort of imitation jurisdiction, modelled all the way after the real. The act caused more embarrassment than it relieved, and in fact it has been practically annulled by the supreme court by decisions which declared subsequent to its enactment that the admiralty and maritime jurisdiction given by the constitution was not in fact limited to the high seas and tide waters, but, by its own proper force, covered as well the great interior lakes and rivers wherever they were navigable, so that the act of 1845 was unnecessary and inoperative.—As to the subject matter, it may be said generally that the American admiralty exercises a jurisdiction based largely upon that of the English court in the time of Edward III., and embraces all maritime causes of action, as well matters of contract as matters of tort, and under the latter covers all injuries and damage done upon the seas, even though done in a port or harbor or within the body of a county. With reference to the contracts which are within the reach of the court, the distinction must be first made between those which directly and of themselves touch maritime affairs, and those which are only preliminary or subordinate to such agreements; for the former the court will pass upon, but it will not upon the latter. Thus a charter party or, as within a year or two it has been decided, a policy of marine insurance is a maritime contract which the court will aid in enforcing; but it has no power in respect to an agreement to make a charter party or a policy. The distinction in these cases is rather obvious and reasonable, but it is not so clear as to some other cases. For example, the earlier maritime law, as it was administered in those periods and courts to which our court appeals for tests of jurisdiction, covered all contracts which concern the ship, and thus included all contracts for building, repairing, supplying, or equipping her. But as to a contract for building a ship, our supreme court has held that it was not within its jurisdiction. It may be observed, however, that the court in Massachusetts has since decided the contrary, and also that the recent English admiralty court acts expressly confer jurisdiction in such cases upon the court. The court does without hesitation entertain suits by material men for repairing and supplying the ship and for towing her, and even claims for shipping a crew and procuring a cargo; but it has declined to hear actions by stevedores and ship keepers, or claims for advertising the vessel for sea or preparing her cargo for stowage, or for the wages of lightermen, and even claims for scraping the ship's bottom preparatory to coppering her. The jurisdiction

also includes what are called possessory and petitory actions respecting a ship—that is to say, cases in which the title to possession of the ship is involved, and cases of dispute between part owners as to their interests in the employment of the vessel; contracts of affreightment, either at the instance of the owners for their freight, or of the shippers for damages for the non-fulfilment of the contract of carriage, and also contracts for the carriage of passengers; cases of jettison and average, bottomry and respondentia bonds, and all hypothecations of ship or cargo; of salvage, collision, surveys, and sales of condemned vessels; demurrage, pilotage, and wharfage, and seamen's wages—and all persons stand on the footing of seamen who serve or are useful in the navigation of the ship, including cooks and carpenters, coopers on whaling voyages, and firemen and engineers and deck hands on steamboats. The court has also jurisdiction of all assaults and batteries, imprisonment or improper treatment of sailors or of passengers, and all other damages and injuries done on the high seas and navigable waters, and also of questions of prize and of seizure under the revenue and navigation laws. (See PRIZE.) With respect to the relations of the federal and the state courts, it is now settled, but it was not until very lately, that the jurisdiction of the former in admiralty suits *in rem* is exclusive, and consequently none of the states can give their local courts power, under statutes, to enforce liens *in rem* which are of a purely maritime and admiralty nature.—Though the court of admiralty exercises its jurisdiction upon principles of equity and natural justice, and may administer equitable relief upon a subject which is fairly within its characteristic powers, yet it is not in the ordinary sense a court of equity, and cannot intervene in that class of cases which are peculiarly passed upon in such a court; and though it construes the contracts and obligations of parties before it less strictly than the courts of common law, and will mitigate the severity of contracts or moderate exorbitant demands, yet it will not assume to go further and grant purely equitable relief. Thus it cannot entertain a bill for the specific performance of a contract for the sale of a ship, for the execution of a trust, for the correction of a mistake, or the reformation of an instrument, on that ground, or grant relief against fraud; and it was even expressly held that it cannot in general order an accounting between part owners, or aid in cases of mortgage of a ship so as to decree foreclosure, or vest title in the mortgagee upon a sale. The court in its equitable spirit will also disregard technicalities in procedure, and looks at the matter rather than the form, to the end that the party entitled to it shall receive substantial justice without regard to formal irregularities or defects.—In the United States there are no courts which possess an admiralty jurisdiction solely. It is exercised in all cases by the fed-

eral courts, as a branch and part of the full powers delegated to them. The original jurisdiction is vested exclusively in the district courts. From these appeals lie to the circuit courts in admiralty and maritime causes, when the matter in dispute exceeds the value of \$50, and from these to the supreme court when it exceeds the value of \$2,000. Upon an appeal in admiralty to the circuit court, unlike the course in such proceedings in other courts, the parties may have the whole cause heard *de novo*, and the cause is not in fact *res adjudicata* or finally decided until such appeal is waived or sentence is reached in the appellate court. The case may therefore go before the circuit court upon the same testimony taken below, or the parties may introduce new evidence there and have all the proceedings as well of fact as of law in the court below reviewed. And even the supreme court, sitting on an admiralty appeal, is very liberal in permitting amendments and additions; and if justice require that the pleadings be reformed or a new claim brought into the case, that court will refer the cause back to the circuit court for this purpose. But in regard to appeals brought up on the same testimony presented below, the supreme court has lately declined to reverse decisions as to matters of fact in which the district and circuit courts have agreed.—The practice of the admiralty courts is simple, and their procedure direct and expeditious, and intolerant of technicalities; their administration of the law is liberal and equitable, trusting rather to the matter than to the form, and seeking always to insure quick remedies and to give relief upon the actual merits of the case. The practice is regulated in some of its details by rules framed by the district courts. They differ somewhat in the different districts, but not materially. The forms of proceedings are modelled upon those of the Roman civil law as it has been fashioned in European courts, and especially in European courts of admiralty. The suit is instituted by the filing of a libel, which is a mere statement in the simplest narrative form of the libellant's cause of action. Upon this the court issues its process directing the marshal, in an action *in personam*, either simply to call the defendant into court to answer, or, if such process be prayed for, to arrest him or attach his goods; or if the suit is *in rem*, it directs the marshal to take the thing into his custody, and to give due notice to all persons claiming it to come and show cause why it should not be condemned; the theory of the proceeding *in rem* being that the thing proceeded against, rather than any person, is to satisfy the libellant's action. The defendant puts in an answer, and if he is the owner of the thing proceeded against in an action *in rem*, he puts in also a claim to the property, and may remove the hold of the court upon it by giving a bond for its value. In matters of contract, the cause is brought to a hearing before the judge; and previous to the

final hearing by the court the evidence of witnesses about to leave the district, as for example of sailors or officers of ships, may be taken out of court before its commissioners.

ADMIRALTY ISLANDS, a group in the S. Pacific, N. E. of New Guinea, between lat. 2° and 3° S., and lon. 146° and 148° E. They consist of one large island, Admiralty or Basko, in the centre of the group, between 50 and 60 m. long, one (Matthew) of about 117 sq. m., 150 m. N. E., and 20 or 30 much smaller ones. They are generally low and fertile, though Basko has high mountains, and abound in cocoanut trees. The inhabitants are nearly black, well formed, and of good features, and go almost naked. The islands were discovered in 1616 by a Dutch navigator, Cornelius Schooten (hence sometimes called Schooten's islands), rediscovered in 1767 by Carteret, who gave them the present name, and have been very seldom visited since, access being difficult on account of the coral reefs which surround them.

ADMONITION, a part of ancient church discipline. If the offence was of a private nature, the warning was given in private; otherwise before the assembled church. If the person censured did not amend his ways, excommunication followed.

ADOBE HOUSES, dwellings built of unburnt brick, in common use in Mexico, Texas, and Central America. Adobe bricks are made of loamy earth, containing about two thirds fine sand and one third clayey dust, which under the action of the sun becomes a hard, compact mass, without a crack. Four men generally work at the making of these bricks, one to mix the mass, two to carry it in a hand-barrow, which is sprinkled with finely powdered dry manure or dust to prevent adhesion, and one to mould the prepared substance into bricks. The moulds are double, each 16 to 18 inches long, 9 to 12 inches wide, and 4 inches thick, and have projecting handles at each end, but no bottom, the brick being deposited on the surface of the ground, which has been previously levelled; and the adobes are carefully turned on the edge, and left to harden in the sun. They are laid with mud mortar, made from the earth at the foot of the wall; and on the completion of every two feet of the structure, an interval of one week is allowed for drying, and a similar space of time between the completion of the walls and fixing of the roof. The houses are usually one story high, and the inside plastered before the roof is put on, so that it may dry with the walls. An adobe house costs little; it is warmer in winter and cooler in summer than either wood or brick, and its duration is extraordinary, adobe houses 50 feet high being in existence which have stood for more than a century.

ADOLPHUS. I. John, an English advocate and author, born in London in 1766, died July 16, 1845. He studied in London, was admitted attorney and solicitor in 1790, and was called to the bar in 1807. He soon obtained the

character of an adroit, skilful counsellor, and practised chiefly at the Old Bailey in criminal cases. His forensic reputation was not fully established till 1820, when, on the trial of the "Cato street conspirators," he defended Arthur Thistlewood, charged with high treason, with marked ability, though his client was convicted. From that time his practice at the bar was large and lucrative, but his warmth of temper frequently led him into undignified squabbles. His reports are referred to as authority. His principal works are: "The History of England from the Accession of George III." (3 vols., 1805, of which a new edition enlarged to 7 vols., but still unfinished, appeared shortly before his death), and "Biographical Memoirs of the French Revolution." See "Recollections of John Adolphus," by his daughter (1871). **II. John Lyecester**, a barrister, son of the preceding, highly distinguished himself at the university of Oxford, and published in July, 1821, a work which Lockhart says "was read with eager curiosity and delight by the public, with much diversion, besides, by his [Sir W. Scott's] friends, and which Scott himself must have gone through with a very odd mixture of emotions." This book is entitled "Letters to Richard Heber, Esq., containing critical remarks on the series of novels beginning with Waverley, and an attempt to ascertain their author." The purpose of this book was to prove, from Scott's acknowledged writings, and from other known circumstances connected with his personal history and position, that he and none other could be the author, sole and unassisted, of the Waverley novels.

ADOLPHUS FREDERICK, of Holstein-Entin, king of Sweden, born May 14, 1710, died Feb. 12, 1771. In 1727 he was elected prince-bishop of Lübeck as successor of his father. On the death of his cousin Charles Frederick, duke of Holstein-Gottorp, in 1739, Adolphus Frederick became the administrator of his possessions during the minority of his son, afterward Peter III. of Russia. The king of Sweden, Frederick of the house of Hesse-Cassel, being childless, and the young duke of Holstein-Gottorp having declined to become heir apparent at a time when he hoped to succeed to the throne of Russia, it was decided in 1743, by virtue of the treaty of Abo between Russia and Sweden, that Adolphus Frederick should occupy the position, so that it might be at all events vested in the Holstein family. The grandmother of Adolphus having been a daughter of Charles XI. of Sweden, this circumstance was also regarded as favorable to his election, which was ratified by the Swedish diet on July 3, 1743. In 1744 he married Louise Ulrike, a sister of Frederick the Great, and he ascended the Swedish throne April 5, 1751, on the death of King Frederick. The aristocracy being favorable to France, Sweden was dragged into the seven years' war against Prussia; and the attempts of the queen to oppose this policy

resulted only in bringing the ring-leaders against the aristocracy to the scaffold (1756). The council of state sided with the aristocracy against the crown, and it was only after the king's threatening to abdicate that the Swedish diet consented to sustain his rights and protect him against the aggressions of the nobles. He was an upright prince, but by his meekness he encouraged the schemes of France and her allies among the nobility. He was succeeded on the throne by his son Gustavus III.

ADOLPHUS OF NASSAU, a German sovereign, born about 1250, fell in battle near Worms, July 2, 1298. He was the second son of Walram IV., count of Nassau, and was distinguished for valor in the service of Rudolph of Hapsburg. On the death of the latter he was, at the suggestion of the archbishop of Mentz, unanimously elected as his successor (May 10, 1292), in place of Rudolph's son and heir Albert. He was crowned at Aix-la-Chapelle as king of Germany, June 24, 1292, but not in Rome as emperor. Adolphus disgraced himself by accepting an English subsidy of £100,000 for joining in the war against France, and by backing out of the bargain without restoring the money. He further lost caste by his mercenary but fruitless transactions with the landgrave Albrecht of Thuringia for the acquisition of his territory. The archbishop of Mentz, in concert with Albert of Austria, caused Adolphus to be arraigned before the college of electoral princes. On his declining to comply with the summons, his deposition was proclaimed, June 23, 1298. But Adolphus appealed to the arbitrament of arms. The rivals met, with their respective armies, between the villages of Gölheim and Rosenthal, near Worms. Adolphus fell, hit in the face, as was reported at the time, by the lance of Albert, whose companions gave him the death blow. Under Henry VII. his remains were placed beside those of his successor Albert I., in the vault of German sovereigns at Spire.

ADONAI, one of the appellations of the Supreme Being in the Hebrew Scriptures, signifying Lord, or my Lord. The Jews, who refrain from uttering the name of Jehovah, pronounce Adonai in its place where it occurs in the Hebrew text, in which they have also substituted the vowels of Adonai for those of the name, thus rendering the right pronunciation of the latter doubtful.

ADONIA, feasts anciently held in honor of Venus and Adonis. They lasted two days; the first was spent in tears and lamentations, the second in mirth and feasting. The festival typified the dying and resurrection of nature.

ADONIS, in Greek mythology, a beautiful youth beloved by Venus. According to the account received from the cyclic poet Panyasis, he was the son of Theias, king of Assyria, and his daughter Smyrna. Venus, discovering the beauty of the child, hid him in a chest, which she intrusted to Proserpine. Hence resulted the dispute between these goddesses as to

which of them Adonis should belong to, which was settled by the judgment of Jupiter that he should remain with each of them an equal part of each year. Adonis died of a wound received from a wild boar in the Italian woods, and the sorrow of Venus for his loss was so great that the gods allowed his return to earth for six months of every year to console her.

ADOPTIANI, a Christian sect in Spain, founded by Elipandus, archbishop of Toledo, and Felix, bishop of Urgel, near the close of the 8th century. They affirmed that Jesus was really the son of God only in his divine nature, and the son of God by adoption merely in his human nature. So long as they confined their efforts to spreading their views in the Mohammedan territory, no notice was taken of the new sect. But when, through the efforts of Felix, whose diocese belonged to the Frankish empire, adoptianism began to spread in the dominion of Charlemagne, the subject was brought to the notice of that emperor, and the synod of Ratisbon (792) condemned it as a renewal of the Nestorian heresy. Felix recanted, and confirmed his recantation before Pope Adrian in Rome. But after his return to Urgel he reaffirmed his adoptian views. At the request of Charlemagne Alcuin wrote an epistle to Felix against adoptianism. This step, however, had no results; on the contrary, a number of the Spanish bishops declared their agreement with Felix. A new synod convened at Frankfort (794) ratified the decrees of Ratisbon against adoptianism. Finally, Archbishop Leidrad of Lyons prevailed upon Felix in 799 to appear before a synod at Aix-la-Chapelle, when, after a protracted discussion of the subject with Alcuin, he once more recanted. Felix was now committed to the charge of Leidrad at Lyons, where he died in 816. Elipandus never retracted his opinions, but soon after his death the sect became extinct. Adoptianism was the first important theological controversy concerning the person of Christ originating in the western church.

ADOPTION, the taking of another's child as one's own, still regulated by law in Germany and France, as it was in Rome. Where the party adopted is under age, and actually under the parents' power, it is called adoption proper; but where it is of age, *sui juris*, adrogation. The abstract rule that adoption must imitate nature, though derivable from regulations of the Roman law, such as that forbidding eunuchs to adopt, and that requiring the adopter to be at least 18 years older than the adopted, is not fully carried out, since by the same law those incapable of procreation may adopt. In Germany, while the child is more completely absorbed into the family of the adopter than he was in Rome, numerous subtle distinctions have been engrafted upon this title of the law; while the *Code Napoléon* admits adoption only to a limited extent. A prerequisite to adoption in Rome was leave from the college of priests;

in Germany the sanction of the prince or judge is required. In Texas, a person may adopt another to be his legal heir by filing a statement, authenticated like a deed, expressing his intention so to do, with the county clerk, thereby entitling him to all the rights and privileges of a legal heir, except that if the adopter have a legitimate child or children, the adopted shall in no case inherit more than a fourth part of the testamentary estate of the adopter. In several of the states adoption has been made the subject of recent statutes; for example, in Illinois (1867) and Kansas (1868). The proceeding under these acts is in general similar to that which has existed for a long time in Massachusetts. In that state, any person may present a petition to the probate court for the adoption of a child not his own, and, if desired, for a change of the child's name. If the petitioner has a husband or wife, the application will not be entertained by the court unless such husband or wife join in it. The consent of the child's parents, or of the survivor of them, must be procured in writing; or if it has no parent, its guardian or next of kin or some person appointed by the court must give the requisite consent. And the adoption will not be sanctioned without the child's consent, if it is more than 14 years old. The child thus adopted, for all purposes of inheritance, and in respect to all the other legal consequences and incidents of the natural relationship of parent and child, is deemed the child, born in lawful wedlock, of the person who adopts it, except that it shall not take property limited to the heirs of the body of the new parents, nor coming from their collateral kindred. An appeal from the decision of the probate court upon the petition lies in favor of either the petitioner or the child to the supreme court; and any person interested who had not actual notice of the proceeding may apply within a year for a reversal of the order of the probate court. In Louisiana the proceedings are more like those of the civil law. The person adopting must be at least 40 years old, and at least 15 years older than the person adopted. Married persons must concur about the adoption.

ADOUR (anc. *Aternus*), a river in the S. W. of France, about 180 m. in length, 70 of which are navigable. Its course is nearly semi-circular. It rises in the Pyrenees, flows through the departments of Hautes-Pyrénées, Gers, and Landes, and empties into the bay of Biscay, a little below Bayonne. Though many streams unite with it, its volume of water is small, except during the melting of the snows in the Pyrenees, when it often inundates the surrounding country.

ADOWA, one of the chief towns of Abyssinia, capital of Tigré, about 145 m. N. E. of Gondar; pop. about 8,000. It is the great depot of the trade in cattle, corn, salt, and slaves, between the coast and the interior. The chief manufactures are of cotton.

ADRASTEIA (Gr. Ἀδράστεια, she whom none can escape), in Greek mythology, a goddess of just retribution, like Nemesis, or, according to some of the poets, identical with her.

ADRASTUS, a legendary king of Argos, in the history of ancient Greece. His father was Talaüs, king of Argos. Being expelled from Argos, he took refuge in Sicily, and there succeeded to the throne, and instituted the Nemean games. He was subsequently restored to his native city, and married one of his daughters to Polynices, son of Œdipus and brother of Eteocles, who had been deprived by the latter of his share in the reign over Thebes. He now formed a union of Greek heroes to restore his son-in-law to his throne, and led the famed expedition of the "seven against Thebes," the abundant theme of later tragedy. Adrastus alone survived, saved by the fleetness of his horse Arion. Ten years later he prompted the seven sons of the defeated heroes to renew the war. Their expedition, known as that of the epigoni or descendants, set out with promises of success from the oracle, and ended with the capture and complete demolition of Thebes. The son of Adrastus was the only Argive that fell, and Adrastus himself soon after died of grief.

ADRIA, a town of Italy, in the Venetian province of Rovigo, on the canale Bianco, between the mouths of the Adige and Po, 30 m. S. by W. of Venice; pop. 13,000. The inundation of these rivers gradually rendered the country uninhabitable, and their deposit of soil caused the sea to recede until the town, anciently a seaport, is now 14 m. inland. It is a bishop's see, and has a celebrated museum of Etruscan and Roman antiquities. The ruins of ancient Adria, or Hadria, founded by the Etruscans, lie S. of the modern town. The name of the Adriatic sea is derived from it.

ADRIAN, a city and the capital of Lenawee co., Mich., on the S. branch of the Raisin river, and on the Michigan Southern railway, 74 m. W. S. W. of Detroit; pop. in 1870, 8,438; in 1860, 6,213. The city is well built and paved, and lighted with gas. It commands the trade of an extensive grain-growing region. The stream on which it is situated furnishes good water power. The principal industrial establishments are: a car factory employing 250 men, a brass foundry employing 100, two iron foundries, two sash factories, two planing mills, two organ factories, and three flour mills. The city possesses a fine monument to the memory of 77 citizens of Adrian who fell in the civil war. There are eleven churches and five public school houses. Adrian college, founded in 1859 by the Protestant Methodists, admits both sexes, and has an average attendance of about 160 students. The central union school building is one of the finest in the West. Three papers are published here, one monthly (educational), one weekly, and one daily and weekly. The first house in Adrian, a log dwelling, was built in 1826. The

village was laid out in 1828, and it was incorporated as a city in 1853.

ADRIAN, a Roman emperor. See **HADRIAN**.

ADRIAN, the name of several popes. **I.** Born at Rome, succeeded Stephen IV. in 772, died Dec. 25, 795. Desiderius, king of the Lombards, having invaded the provinces which Pepin had presented to the Roman see, Adrian solicited the assistance of Charlemagne, who entered Italy, and overthrew the power of the Lombards in 774. In return the Frankish conqueror received from Adrian the title of king of Italy and patrician of Rome. In 791 Rome was inundated by the Tiber, when Adrian distributed provisions in boats. He also rebuilt the fortifications of Rome. **II.** Born at Rome, succeeded Nicholas I. in 867, and died in 872. He had been married, but left his wife to live in celibacy. During his pontificate the schism between the Greek and Latin churches was begun by the secession of Photius, patriarch of Constantinople. **III.** Born at Rome, was made pope in 884, and died in 885, on his way to the diet at Worms. **IV.** **NICHOLAS BREAKSPEAR**, the only Englishman who ever filled the papal chair, became pope in 1154, and died in September, 1159. He is said to have left England as a beggar, became a monk and afterward abbot of St. Rufus in Rome, and was made cardinal bishop of Albano by Eugenius III., who sent him as his apostle or legate to Norway and Denmark. On the death of Anastasius IV. he was, much against his will, elected pope. Rome was at this time in a state of great confusion, resulting from the reformatory preaching of Arnold of Brescia. Immediately after his election he placed Rome under interdict, prohibited all religious services, and banished Arnold, who was subsequently surrendered on Adrian's demand by Frederick Barbarossa, and tried and executed at Rome. Shortly afterward Adrian crowned Frederick emperor of Germany; but some trifling dispute occurring as to the forms to be observed in the ceremony, a general conflict took place between the Roman and German troops, in which many lives were lost. Adrian afterward became involved in numerous quarrels with Frederick, which was the origin of that bitter enmity between the papal see and the Hohenstaufens, which ended only with the fall of the latter. **V.** A Genoese, succeeded Innocent V. in 1276, and died five weeks after his election. **VI.** Son of an obscure mechanic of Utrecht named Boeijens, born in 1459, died Sept. 24, 1523. He was known only by the name of Adrian, was educated at Louvain, and became professor of theology there and vice chancellor of the university. Maximilian I. chose him as preceptor of his grandson (Charles V.), and subsequently sent him as ambassador to Spain, where he became bishop of Tortosa. After the death of King Ferdinand (1516) he shared the regency with Cardinal Ximenes, and in 1517 was made cardinal. On the departure of Charles V. for Germany

in 1519 Adrian was left sole governor, and showed remarkable feebleness in his treatment of a powerful insurrection (war of the communities, or of the holy league) caused by oppressive taxes, and especially by the excessive favors showered upon the Flemings, but which was finally suppressed by a council appointed by Charles V. He was elected pope in 1522, as successor of Leo X., and entered Rome Aug. 31. The simplicity which he introduced at the papal court, contrasted with the magnificence of his predecessor, excited contempt and discontent among the people; while his ecclesiastical reforms, and his humility in acknowledging the errors of the papacy while dealing with the schism of Luther, were very distasteful to the clergy. He was the author of several pious works, in one of which, published after his accession, though written previously, he held that a pope might err even in matters of faith.

ADRIANOPLE (anc. *Hadrianopolis*; Turk. *Edirneh*; Fr. *Andrinople*), a city of European Turkey, capital of the vilayet of Edirneh, situated on the Maritza (the ancient Hebrus), in ancient Thrace, about 130 m. N. W. of Constantinople. The population is variously estimated from 100,000 to 150,000, at least one third of whom are Greeks, and the rest Turks, Armenians, Jews, Franks, &c. The scenery of the city is beautiful; the gardens on the banks of the Maritza and the neighboring village of Hisekel, inhabited by the wealthy merchants, are delightful; but the interior of the straggling city is, like that of most Turkish towns, dirty and desolate. Even the picturesque effect of the 40 mosques, among which is the famous one of Selim II., built of materials furnished by the ruins of Famagosta in Cyprus, is impaired by the wretched surroundings. The most capacious bazaar, named after Ali Pasha, is the centre of trade, which is considerable, the city being the focus of the whole of Thrace. It is also the residence of a governor general, a Greek archbishop, foreign consuls, and missionaries. Wool, silks, cotton, dyestuffs, carpets, opium, and attar of roses are the principal articles of commerce. Quince preserve is one of the special products of Adrianople.—The town was founded by the emperor Hadrian, and soon attained great commercial and military importance. It was the scene of famous encounters in the times of the Romans, the Byzantine empire, and the crusades. Frederick Barbarossa concluded a treaty there in 1190 with the Greeks, and Baldwin I. was defeated and captured in the city in 1205 by the Bulgarians. Taken by the sultan Murad I. in 1361, it remained the Turkish capital until the taking of Constantinople in 1453. Charles XII. spent some time in 1713 in the neighboring castle of Timurtash, previous to his residing at Demotika. In 1829 Adrianople was captured by the Russian general Diebitsch, and a treaty of peace was signed there on Sept. 14, 1829, between Russia and Turkey, in virtue

of which the Danubian principalities were restored to the Porte. The Pruth, and from its mouth the Danube, were made the dividing line between the two countries, and the boundaries of their respective Asiatic possessions were agreed upon. Russia obtained the privilege of trading with all parts of the Turkish empire, the navigation of the Danube, the Black sea, and the Mediterranean, and the passage of the Dardanelles, upon the same terms with the most favored nations, besides a full indemnity for her war expenses.

ADRIATIC SEA, the portion of the Mediterranean lying between Italy on the W. and Turkey and Austria on the E., takes its name from the city of Adria. Its length from the strait of Otranto (which connects it with the Ionian sea) to the head of the gulf of Trieste is about 500 m.; its average width about 130 m., which, northward from the mouth of the Po, is reduced to about 60 m. by the peninsula of Istria. The Adriatic receives few rivers of importance, except the Adige and the Po. The western coast is generally flat and swampy; its harbors are few and poor. The eastern shores are steep and rocky, and the numerous islands along the Dalmatian coast furnish vessels a safe shelter from storms. The northwestern part of the Adriatic is known as the gulf of Venice, the northeastern as the gulf of Trieste. On the Neapolitan coast lies the gulf of Manfredonia, on the Dalmatian the gulf of Cattaro, and on the Albanian that of Drino. During summer the navigation of the Adriatic is usually free from danger, but the S. E. winds that blow in winter produce disastrous shipwrecks. Its depth between Dalmatia and the outlets of the Po is 22 fathoms; but opposite Venice, and in a considerable portion of the gulf of Trieste, it is less than 12 fathoms. To the southward it deepens rapidly. Its waters are more salt than those of the Atlantic. The tides are almost imperceptible. There can be little doubt that the dimensions of the Adriatic were formerly much greater than at present, and that they have been contracted by the deposits of mud made by the streams that empty into it. On the western coast several lagoons produced by sand bars are being rapidly transformed into meadows by this process. The original depth of the Adriatic has likewise been diminished by the accumulations of sandy marl and testaceous incrustations at the bottom.

ADULLAM, a town of ancient Palestine, in the lowland of Judah, the seat of a Canaanitish king before the Hebrew conquest. It was fortified by King Rehoboam. Its location, like that of the "cave of Adullam," where David hid when pursued by the Philistines, has not yet been sufficiently identified.

ADULTERATION, a term applied to the deterioration of different articles of food, drugs, &c., by mixing them with cheap and inferior substances. The microscope has become a very important instrument in detecting fraudulent mixtures. In wheat flour it detects the mix-

ture of rice flour, and in the maranta arrow-root it exposes the peculiar structure of the cheap potato flour and sago. In mustard and coffee it brings out the peculiar forms of chicory root; and in the former turmeric has been detected by it, when this was added only in the proportion of $\frac{1}{500}$ part. Poisonous ingredients, being mostly of a mineral nature, are subjects rather of chemical analysis than of microscopic examination. There is an instance, however, of cattle having been poisoned by eating rape or oil cake, in which were detected by Dr. Hassall the ground seeds of the mustard. Chemical analysis in such a case could discover nothing. It is to Dr. Hassall, the author of scientific papers in the London "Lancet," and of several works on food and its adulterations, that the credit is principally due for the progress made in this department of science, at least in its applications to this subject. In some vegetable powders, Dr. Hassall has succeeded in detecting nine different vegetable productions. The mineral poisons that are made use of to give light colors to confectionery, and the fine green shades to pickles and to tea, are only brought to view by chemical analysis. By these, however, they are separated quantitatively, and in forms that are recognized by every one. The mistaken taste of the public for very white bread leads the baker to select the flour from which the more nutritious portion of the grain has been separated by the miller, and to make this flour still more white he adds to it a quantity of alum. Though the use of this substance in bread is forbidden by law in England, it was found in every one of 53 samples that were examined for it. Cheaper and less nutritious kinds of flour, as of rice, potatoes, corn, beans, rye, &c., are mixed with wheaten flour, some of which, besides their direct effect in lessening the value of the article, also cause the bread to absorb much more water, and thus add to its weight by substituting water for flour. Carbonate and sulphate of lime, silicate of magnesia in the form of soapstone, white clay, carbonate of magnesia, bone dust, and bone ashes, have all been detected in flour in England. In the adulterations of tea, especially green tea, the ingenuity of the Chinese is taxed before it leaves their country, and that of the English on receiving it in their own. The list of other plants which furnish leaves for the tea chests, and which are recognized by the microscope, is too long for repetition here, and so of the poisonous mineral ingredients, including arsenite of copper, which are skillfully used to make good green teas of unsalable black teas. Coffee fares somewhat better, its adulterating mixtures being of a more harmless nature, such as chicory, acorns, mangel-wurtzel, peas, and beans, and for the use of the poor in London roasted horse liver. In an analysis made in 1872, under the direction of the Massachusetts board of health, a pound package of a mixture sold as ground coffee was found to contain no coffee

whatever; but coffee sold in bulk was nearly always found pure. Sugars are more decidedly free from adulteration, but the brown sugars, as usually imported, are found from the accidental impurities present, and from the immense numbers of live animalcules, to be in a state unfit for human consumption. The white lump sugars are very pure, and any insoluble substance like sand can be easily detected. No articles, however, have been the subjects of such a reckless system of adulterations as the colored sugar confectionery. Though expected to be used principally by children, the colors painted upon the candies and sweetmeats are the product of virulent mineral poisons; and it is wonderful what a variety of these have been made applicable to this purpose. Their use, however, is not now nearly so great as it was in former times, and is discountenanced by reputable dealers in these articles.—Wines and spirits, from their high value and general use, as also from the difficulty of detecting the cheap mixtures added to them, are almost universally adulterated to some extent; while many are made up entirely of ingredients wholly foreign to the country which produces the genuine wine. The substances added with a view of preserving wines are sometimes poisons, lead and copper both being used, the former in the state of litharge. In England the favorite port wine is thus most shamefully treated, besides being manufactured on a very large scale, after a variety of curious recipes, from thousands of pipes of spoiled cider imported for the purpose, bad brandy, and infusions of logwood and other dyestuffs. The champagnes, which are more in demand in this country, find here as ingenious imitators; and from our native ciders, with a due mixture of cheap French wine, sugar, brandy, and a little lemon or tartaric acid, more champagne is bottled than ever crosses the Atlantic. If gooseberry wine is easily obtained, it is used instead of cider for making good champagne. The impossibility of supplying the demand for French brandy, and the consequent high price of the article, have led to its extensive manufacture in France from very cheap materials. These materials are water and spirits obtained from molasses, beet root, and potatoes, and more particularly cheap whiskey, which is sent from this country in large quantities to come back brandy. Burnt sugar gives the desired color, and the fine flavor is made to suit the taste by skillful admixtures of essential oils and distilled murk, which is the refuse skins and pips of the grape left after the wine is expressed. This stuff is imported into England, to be distilled with molasses for making brandy. Gin is largely adulterated with water, and as the effect of this is to make the liquor whitish and turbid, other substances must be added to correct this and "fine" the gin. These are alum, carbonate of potash, and the poisonous acetate of lead. To restore its strength and pungency, cayenne

in the form of tincture of capsicum, or grains of paradise, are employed; and its peculiar aroma is preserved by compounds called "gin flavorings," the ingredients of which are juniper berries, coriander seeds, almond cake, angelica root, licorice powder, calamus root, and sulphuric acid. The common whiskey of the country is largely diluted in the distilleries with water, and then to restore the strength the lye of ashes, which is prepared for the purpose, is added in sufficient quantity to give the liquor the character which is expressed by the slang name by which it is called of "rot-gut." The report of the Massachusetts board of health, already referred to, shows that the adulteration of vinegar with sulphuric acid is extensively practised, especially in wine vinegars. Lead is also found in vinegar, often coming from lead faucets.—It has been supposed that the adulteration of drugs was very generally practised, and almost without check. Were this the case, medicine would indeed be in bad repute; for in no department would this practice be followed by more disastrous consequences. That it is largely adopted, the analyses of our most respectable druggists prove; but these also show that the system may be exposed, and in a great measure checked, by those disposed to do so; and further, that the articles used for sophistication are generally of a very harmless nature. In July, 1848, a law went into effect in this country, forbidding the importation of these dangerous mixtures. But while the effect of this has been to exclude foreign adulterations, the manufacture of them at home has been greatly increased. In the first year after its establishment, it appears by the report of Dr. J. M. Bailey to the New York academy of medicine that over 90,000 pounds of drugs, comprising Peruvian bark, rhubarb, jalap, senna, and various other kinds, had been rejected and condemned in the ports of the United States. It is very questionable, however, among druggists, whether after all the sale of spurious medicines has been seriously diminished. The adulteration of Turkey opium is carried on as a regular business at Marseilles. It is there literally made over again. The greatest variety of impurities are introduced into it; besides extracts of the poppy and other plants, sand, ashes, gums, aloes, small stones, pieces of lead and iron, seeds and stems of plants, are freely used. In England the same practice has been so successfully pursued, that what appeared to be the best Turkey opium has proved entirely destitute of the active principle of the drug. The essential oils, used more particularly for perfumery, are especial objects of adulteration. Oil of wormwood, we notice upon the test book of one of our most respectable druggists, "warranted pure from Boston," contained about 40 per cent. of a mixture of chloroform and alcohol, besides some resin or fixed oil. Such adulterations may be detected by the greatly reduced boiling point of the fluid. Scammony, which is

extensively used as a drastic purgative, was before the passage of the law always very impure. At Smyrna its adulteration is still a regularly established business. The article called cake scammony, bought and sold in this country, is considered good if it is found to contain 20 per cent. of the genuine material; and virgin scammony passes if it contains no more than 20 per cent. of foreign matter. This is usually starch. Chalk and flour are also used.

ADULTERY, the voluntary sexual intercourse of a married person with another than the husband or wife. As a topic of the law, adultery may be considered, first, as a ground of divorce; second, as a criminal offence. 1. *In civil cases.* The adultery of either party to the marriage contract is now a ground for absolute divorce in almost all Protestant states. It was not so, however, either in Scotland or England until the reformation; and after that, though in the former country divorces *a vinculo* were allowed for adultery, the law remained unchanged in England for a long time, and as it had been administered in the spiritual courts ever since the Catholic period; and by the ecclesiastical law marriage was held to be an indissoluble contract, and divorces from it were prohibited. The consequence was, that though divorces *a mensa et thoro*, or rather separations from bed and board, were granted, the only absolute divorces to be had in England were those procured from parliament upon petition. Proceedings of this character were very expensive and cumbrous; and besides, it was the almost uniform practice of parliament to grant divorces to husbands only, and to refuse them to wives. The divorce act of 20 and 21 Victoria, ch. 85, has partly removed this invidious distinction; but not even now have husband and wife in England equal legal rights and remedies in this respect. Under this statute the husband may have a dissolution of the marriage when the wife has since its celebration been guilty of adultery; but the wife may have such relief only when the husband since the marriage has been guilty of incestuous adultery; or of adultery with bigamy; or of rape, sodomy, or bestiality; or of adultery coupled with such cruelty as, without adultery, would have entitled the wife to a divorce from bed and board before the statute; or of adultery coupled with desertion without reasonable excuse for two years and upward. The incestuous adultery of this statute is declared to mean adultery with a woman with whom the husband could not have contracted a valid marriage, on account of her relationship to him within the prohibited degrees of affinity or consanguinity; and the bigamy of the statute means marriage of the husband with another woman during the life of his lawful wife, whether within or beyond the realm.—It has been shown that by the common law of England, at the time of the settlement of this country, adultery was ground only for a divorce *a mensa*; and as our law followed that of the

parent state, the common law of the United States was to the same effect. But as the power to grant such divorces was vested in England in the ecclesiastical courts, and no such tribunals were ever erected here, the jurisdiction over divorces was granted to our common law courts by special statutes. But these statutes did not limit the relief, as in England, to mere separation, but have almost universally made adultery the cause for absolute divorce; also, here as in Scotland, the law makes no distinction in favor of the husband, but administers the remedy in favor of either party to the marriage, and for the same grounds.—In reference to divorce, it is immaterial whether the paramour of the adulterous husband or wife be married or single. It is essential to the action for divorce that the adultery be voluntary. Thus a woman is not guilty of it in having intercourse with a man whom she innocently supposed to be her husband, nor if she committed the act in a state of insanity, or was forced to it by a ravisher. It has been held otherwise in Pennsylvania in regard to insanity, Chief Justice Gibson declaring that insanity so great as to efface from the mind of the wife the first lines of conjugal fidelity will be no defence to the husband's action for adultery. But this seems hardly sound, and it is probably not law in any other state. Adultery may be committed by the contraction of a new marriage under the belief that the former husband or wife is dead, when that is not the fact; for unless the period of absence is the full term prescribed by statute for founding the presumption of death, the mere belief of it is not deemed innocent. But in such a case, if the new marriage is by law not totally void, but only voidable, the essential adultery is not committed unless the parties continue to cohabit after the passing of a decree against them; and even when a divorce regular in form has been procured, if it was invalid in fact, either because the party defendant was not within the jurisdiction or power of the court which granted it, or for any other reason, the plaintiff in the divorce suit may be guilty of adultery in contracting a new marriage.—The bill or complaint for divorce on the ground of adultery must in general allege the time and place of the commission of the act, and the name of the person with whom it was committed. The principle which requires these specifications is that the defendant is entitled to be informed with reasonable certainty of the nature of the charge made against him, so that he may have an opportunity to prepare his defence intelligently. If, however, the name of the paramour is not known to the complainant, the allegation on this point may be to the effect that the act was done with some person unknown, and this will suffice if the bill is in other respects specific enough to make the charge definite and certain on the whole. But if the allegation of adultery is based on circumstantial evidence of its commission, as

for example on the fact that the defendant is infected with a venereal disease, or that a wife is found pregnant after such an absence of the husband as precludes the presumption of access on his part, the complaint or libel will be good if, besides charging adultery generally, it suggests such reasonable circumstances as fairly support the allegation.—The charge of adultery is made out by proof of a single act; but it is not necessary that the court or jury which decides upon the case should be furnished with demonstrative proof that the act was committed, or be absolutely convinced of the very time and place when or where it was committed. From the nature of the act, the evidence of it is and must be in the mass of cases only circumstantial. Sometimes the circumstantial evidence is very simple, but of a very convincing character; and sometimes the nature of the case requires the scrutiny, comparison, and interpretation of trains of circumstances which regarded separately are insufficiently criminating. As an illustration of the former sort of evidence, Lord Stowell's remark may be quoted, that "as people, according to the old saying, do not go to bawdy houses to say their paternosters, it is impossible that one can have gone to such a place for any but improper purposes;" and to have done so is universally held to be good proof of adultery. Accordingly, it has been held to be sufficient evidence of adultery, *prima facie* at least, that a man has gone to a brothel and shut himself into a room with a prostitute; and the same is true if a married woman goes to such a house with another man than her husband, or even alone. Of course, in both cases proof of innocence, or better of an innocent purpose, is admissible, though such evidence would not have much weight in most cases. The mere fact that a man and woman live together in the same house, even with the common reputation of being married, while they are not so in fact, would probably not, without other suspicious circumstances, be held sufficient proof of adultery; though it would be otherwise if the parties gave themselves out to be husband and wife. With reference to cases where the intent of the defendant is less clear, and where the approaches to the act have been less bold and open, the courts have used such language as this: that it is impossible to lay down in the form of a rule what circumstances shall or shall not constitute satisfactory proof of the fact of adultery, because the same facts may constitute such proof or not, as they are modified or influenced by different circumstances. But there must be on the whole satisfactory proof that a criminal attachment or purpose existed between the parties, and that opportunities occurred when the intercourse in which it is clear that the parties intended to indulge might have taken place. If, for example, a married woman were shown by undoubted proof to have been in an equivocal position with a man not her husband, leading to a suspicion of her adultery; if it were proved

that she had shown an improper fondness for the man; if they had been detected in clandestine correspondence, had had private meetings, or made passionate declarations; if her affection had been alienated from her husband, or it appeared that her mind and heart were already depraved, and nothing was wanting but an opportunity to consummate the guilty purpose; then proof that such opportunity had occurred in connection with some or all of these other circumstances, according to the nature of the case, would lead to the satisfactory conclusion that the act had been committed. The guilty consummation, in short, may be fairly and conclusively presumed from such circumstances of conduct as, on grounds of common experience and common sense, would lead the discreet and careful judgment of a reasonable and just man to that conclusion. But, on the same principles, the conclusion may not be fairly or justly deduced, even when a witness testifies to the actual fact of adultery; for his testimony may be unworthy of credit, either because he is mistaken or because he does not speak the truth. On this ground the direct but uncorroborated evidence of two prostitutes as to the very act has been held insufficient proof of it; and on the same principle, the testimony even of the paramour of the defendant may require confirmation. Such a person, it has been said, is an accomplice, and all the legal considerations applicable to such a witness must be applied to him or her. Upon the same principles and within the same spirit of construction already suggested, acts in themselves rather innocent and indifferent may take the color of guilt from proof of other circumstances attending them. Thus the mere visit of a married woman to the lodgings of a single man has been held insufficient, alone, to establish criminality; but the act receives a different complexion when there is also proof of correspondence or other improper conduct between the parties. So, though a mere correspondence or intimacy with the alleged paramour would not be by itself sufficient, proof that there had been falsehood or concealment in respect to these things might justify the inference of guilt. Again, the difference between the higher and lower classes of society in their habits of life and social manners must be taken into the account in passing upon the behavior of parties in certain instances. For indelicate acts and demeanor, which among the vulgar may be consistent with innocence, may deserve no such favorable significance when observed among those whose breeding is finer. (See DIVORCE.) II. *The criminal offence.* Adultery, by which is here meant the mere private act, is not a crime nor indictable at common law. Before the famous adultery act of 1650, in the time of the commonwealth, there was no law in England against adultery and the kindred acts as criminal offences. This statute introduced at once the utmost severity, ordaining death for incest and adultery, and three

months' imprisonment for simple fornication, and making a second offence felony without clergy. The act was repealed at the restoration, and nothing was substituted in its place. Adultery, however, has been, theoretically at least, punishable in England by virtue of unwritten law in the ecclesiastical courts, though the offence has never been pursued with any great or systematic vigor; and it may be remembered that Blackstone charges the framers of the canon law with an improper levity in respect to this sort of offences from their own aptitude to commit them. In Scotland there is still, or until very recently there was, on its statute book a law making adultery and incest capital offences. The statute, as to adultery at all events, has been long in disuse.—In many of the United States adultery is made criminal by special statutes, but in as many more it is not criminal. But though the simple act is not a crime in Ohio, Indiana, Illinois, Missouri, Louisiana, and other states, yet in many of them open and notorious adultery is criminal. The nature of the offence of adultery, created by statutes, is sometimes clearly defined by their provisions; but many of the statutes on this head simply declare the punishment of adultery, using the word as if it had a precisely ascertained meaning. In such cases it has been necessary for the courts to determine what acts were intended to be covered by the word; and upon this point has arisen an extreme diversity of opinion on account of the different views which have been taken of the policy of the law on the subject. Thus it has been sometimes said that an unmarried man's illicit intercourse with a married woman is adultery on his part, because he may impose a spurious issue upon the husband; and, upon the same ground, that a man, though married, does not commit adultery in having intercourse with an unmarried woman, because in that case there is no possibility of that result. It has also been said that when either of the parties to the act is married, though the other is not, both commit adultery. In Massachusetts the statute expressly provides that when the crime is committed between a married woman and an unmarried man, the latter shall be deemed guilty of criminal adultery, and be liable to the punishment prescribed for that offence. The statute of Minnesota is to the same effect. In the absence of such provisions, it has been held in New Jersey, for example, that in such a case the man does not commit the crime, and in Virginia that his act is only fornication. In Connecticut the statute provides that "every man and every married woman who shall commit the crime of adultery with each other shall be punished with imprisonment." The statute of Iowa declares that when the crime is committed between persons only one of whom is married, both are guilty of adultery, and shall be punished accordingly. It seems on the whole to be the prevailing and better rule, when positive enactments do not forbid it, that when one of the

parties to the act is married and the other is not, it is adultery in the married one, whether man or woman, and only fornication in the other. From this rule results as the best definition that can be given of the offence, that criminal adultery is the voluntary sexual intercourse of a married person with another than the husband or wife; and this is the position taken by Mr. Bishop, the highest American authority on this and the cognate topics of the law.—Even though the single private act of adultery is not criminal or indictable at common law, yet within the principle that the general law will punish all acts which offend against public morality, adultery may take so gross and openly indecent a form as to be regarded as criminal at common law. But offences of this character are in general made the subject of special statutes. Such crimes, especially the living together in adultery, are not ordinarily regarded by the law as having been committed by mere occasional acts of private intercourse, but there must be proof of a general course of misbehavior, an habitual living or lodging together, though it is not impossible that the complete offence may be committed in a single day. In several of the states it is provided that no criminal prosecution for adultery shall be commenced except on the complaint of the husband or wife of a guilty party.

ADVANCEMENT OF SCIENCE, Associations for the. The British association for the advancement of science was formed in 1831, principally through the energy of Sir David Brewster, supported by Sir Humphry Davy, Sir John F. W. Herschel, Mr. Charles Babbage, Messrs. Forbes, Johnston, and Robison of Edinburgh, and Mr. Murelison of London. The main feature which distinguishes it is an annual gathering of its members, at which each one who has made what he supposes a real advance reads his paper for the criticism of laborers in the same department of science. The association also procures reports upon the state of each particular science, its progress, and its needs, as a guide to inquiry. The effect of the formation of this society upon the state of science in England has been very marked. The first meeting, in September, 1831, consisted of about 200 members; the second, June, 1832, numbered 700; the third, 900; and the fourth, in September, 1834, 1,390. The transactions are annually published in octavo volumes of about 500 pages, and these contain a record of nearly every important step taken in British science during the past 40 years. In the reports included in these transactions are also found the discoveries of continental and American men of science.—The American association for the advancement of science was formed in September, 1847, by the association of American geologists and naturalists. The first meeting of the new association was held in Philadelphia in September, 1848, and although the original association of geologists consisted of only 21 members, 461 names were enrolled in the first list of members of

the new society, which now embraces nearly every scientific man in the United States. The 2d meeting was held at Cambridge in August, 1849; the 3d at Charleston, March, 1850; the 4th at New Haven, August, 1850; the 5th at Cincinnati, May, 1851; the 6th at Albany, August, 1851; the 7th at Cleveland, July, 1853; the 8th at Washington, April, 1854; the 9th at Providence, August, 1855; the 10th at Albany, August, 1856; the 11th at Montreal, August, 1857; the 12th at Baltimore, May, 1858; the 13th at Springfield, Mass., August, 1859; the 14th at Newport, R. I., August, 1860. The 15th was appointed for April 17, 1861, at Nashville, Tenn., but was postponed in consequence of the civil war, and after an interval of several years was finally held at Buffalo in August, 1866. The 16th was held at Burlington, Vt., in August, 1867; the 17th at Chicago, August, 1868; the 18th at Salem, Mass., August, 1869; the 19th at Troy, N. Y., August, 1870; the 20th at Indianapolis, August, 1871; the 21st at Dubuque, Iowa (substituted for San Francisco), August, 1872. The objects and methods of the association are identical with those of the British society. The proceedings of each meeting form an octavo volume of about 300 pages, and this series of volumes contains the most valuable results of American scientific inquiry during the last 25 years. The mathematical papers are not usually published in detail, but the titles of all papers offered at the meeting are published, and thus the volumes furnish at least a record of the growth of American science, a growth partly due, as it is well known, to the influence of this association. The usual number of members is about 700.

ADVENT, the period of four weeks preceding Christmas, appointed by several Christian churches to be observed in honor of the approach of the anniversary of Christ's nativity. It formerly occupied six weeks, and that is still the case in the Greek church. It commences with the Sunday nearest to St. Andrew's day (Nov. 30). In England and some parts of the European continent, marriages can be performed only by special license during this period.

ADVERTISEMENT, a public notification. Announcements in the public journals known as advertisements appeared while journalism was in its infancy. The *Acta Diurna* of the Romans, the *Gazzetta* of the Venetians, and the *affiches* of the French belong rather to the crude devices which led to the creation of journalism than to the history of advertising; while the stamping and bill-posting processes of ancient times, and the fence and rock decorations of to-day, sometimes considered in connection with advertising, are little else than ingenious sign-painting. The advertisement proper arose with periodical literature, and must be considered in connection with its development. The first regular newspaper, "The Certain Newes of this Present Week," published in England in 1622, did not contain any advertisements; but they appeared in some-

thing like a resemblance to the present form in 1652, in a paper called the "Mercurius Politicus." It needed but a short time to popularize the idea, and those notices which are still called "hue and cry advertisements"—for thieves and runaway apprentices—soon became prominent features in the papers. Books were the earliest articles advertised, and were followed by groceries—tea (or, as it was then called, "teha") being the first article of merchandise announced. By 1688 England had added a sufficient number of newspapers to her meagre list to cause advertisements, especially those of popular amusements, to be eagerly looked for. The plague brought the first medical advertisements. Under William and Mary a gratuitous journal was started devoted solely to advertisements. It lived but two years. A similar enterprise a few years afterward succeeded. In 1700 advertising had become very general, and in 1710 we find Addison reviewing the advertisements of his time, "printed with little cuts and figures"—this being the first we hear of pictorial advertisements. In 1800 a crude system of classifying and arranging advertisements was adopted. The further progress of advertising up to the time when the enterprise of the United States pushed it onward may be followed out in the history of the London "Times," which was established in 1788. The "Times" did little to reduce advertising to a system, but it demonstrated its value to the public, and its importance in the economy of newspapers. In 1865 a single number is said to have contained 2,575 advertisements, and other numbers are cited containing still more.—The first printing press was brought to America in 1629. In 1704 the first regular newspaper, "The Boston News Letter," was established. This was often without a single advertisement, and had been published 40 years before its circulation reached 300. It needed 15 years after the establishment of the first paper to add a second and third. With the increase of shipping interests newspapers appeared in larger numbers, and advertisements began to multiply. In 1725 the first newspaper in New York, the "Gazette," was commenced; and in 1728 Philadelphia founded the journal which at its 40th number passed into the hands of Benjamin Franklin. At this time the country contained but seven newspapers. In 1775 there were 34. Then came the war of independence, which put journalism back again; but after its close the country steadily advanced in periodical literature. In 1787 the first daily journal, the "Independent Gazette," was commenced in New York, and in the following year (the same in which the London "Times" was established) it contained 34 advertisements. It seems from these facts that England and America made advertising a serious business more nearly at the same time than is usually supposed. England had largely the advantage, however, in population

and in developed resources. Some of the larger tradesmen in London soon learned that those who advertised most liberally received the most custom. Competition among dealers created a large advertising business, which certain special advertisers carried so far as to astonish the world, until the growth of American advertising enterprise developed the fact that heavy advertising was not so much a bold as a strictly legitimate operation on the part of business men. Various food and medicinal preparations and many fancy articles were advertised in England until the yearly amounts paid the newspapers on account of a single article sometimes reached \$100,000 to \$150,000. Cuts became almost innumerable, and, with crests and monograms, appeared in every paper which would admit them. The advance of journalism in America can, up to a certain time, be best given in its statistics, it being understood that advertising fully kept pace with it and to a considerable extent made it possible. In 1794 the "Commercial Advertiser" was commenced in New York, and in 1801 the "Evening Post." Both journals had considerable influence and grew rapidly. The year 1810 found 32 papers in the state of Massachusetts, and 10 years afterward there were 690 in the United States. In 1830 there were 1,000, and in 1840, 1,401. The New York "Sun," founded in 1833, the "Herald," in 1835, and the "Tribune," in 1841, had introduced some new ideas, which not only enlarged the power and influence of journalism, but greatly popularized advertising. Transient advertising was encouraged, it being discovered that a regular run of small advertisements, at fair rates, continued the year round, paid better than contracts for the same space devoted to long advertisements at low rates, and which lasted only during the business season. A variety in the classes of advertisements was also introduced, and is almost peculiar to American newspapers. For instance, the advertiser could insert, if he chose, amusing "reading" or "local" notices, in which matters interesting the public mind were ingeniously joined with the goods for sale. "Business Notices" and "Special Notices" are other varieties of early adoption, for which higher prices are obtained than for the ordinary advertisement. In 1860 the United States contained the surprising number of 5,253 newspapers. The art of advertising was growing into something like system. Expedients of all kinds were used. Odd and startling cuts were adopted in spite of the newspaper rule (not always enforced) of double prices for such figures; while the old-fashioned, simple style of advertising grew to very large proportions, and enabled almost every village in the country to have its newspaper. As the business became so extensive and the territory to be covered so large, advertising agencies became necessary. These exist to-day in England and continental Europe, but have

by no means the importance which from the nature of the case they have attained in the United States. A few large houses—one of which situated in New York has transactions to the amount of nearly one million dollars per annum—do most of the agency business. It requires a high reputation for responsibility either to obtain the advertising or secure favorable contracts with the newspapers. The method pursued by the better class of agents is simple in principle, but the details require great labor and attention. The largest house in the United States employs about 40 men permanently, and occupies one of the best offices in New York. It has its own printing establishment, and keeps files of nearly 6,000 periodicals. The advertiser gives in his "copy," chooses the papers in which it is to appear, and receives an estimate of the cost. The copy is printed, forwarded to publishers, and inserted in the space contracted for. The agent receives his commission entirely from the paper, though it will be understood that he saves the advertiser large sums in postage or travelling expenses and much time and trouble. The papers, as fast as returned with the advertisements, are entered, checked, and verified, after which they are filed away for the inspection of the advertiser if he desires to examine them. The first advertising agency in America was established in 1828 by Mr. Orlando Bourne, and was followed in 1840 by the founding of similar agencies in Philadelphia, Boston, and New York, by Mr. V. B. Palmer. It was not until about 1860 that anything like full lists of newspapers appeared and the business was systematized. A complete "American Newspaper Directory" is now published by a New York advertising agency, and annually revised; and the same firm publish a weekly "Newspaper Reporter," which fully records the occurrences in the newspaper and advertising world.—The number of large cities in the United States having a powerful and thoroughly organized press would naturally give rise to the supposition that advertising was cheaper here than in England, where the very large papers are few in number. But such is not the case. "Harper's Weekly," for example, considered an important medium for "scattered" advertising, receives from \$1.50 to \$2.50 per line, and "Frank Leslie's Illustrated Newspaper" from \$1 to \$1.50. The "New York Weekly Tribune" receives from \$2 to \$5 per line, the latter price being for notices inserted among the news. The "New York Weekly," a story paper, receives \$3 per line. The "Fireside Companion," "Harper's Bazar," "The Scientific American," and others, charge \$1 per line, although the last-named paper, to protect its smaller advertisers against being overshadowed, has adopted the peculiar rule of charging 25 cents per line additional for advertisements over four lines in a certain part of the sheet devoted to this purpose. The larger dailies in New York receive from 20 to

40 cents per line for ordinary advertisements, and \$1 to \$2.50 per line for notices inserted among the general matter.—The amounts expended by certain advertisers, though often exaggerated, have been very large. Ten years ago, when boldness was less a habit than to-day, \$150,000 was spent by one firm in New York for a year's advertising. Since that time the same sum has been expended repeatedly. A patent medicine dealer in New York has several times advertised to the extent of \$250,000 a year. To advertise to the amount of \$100,000 a year now excites little surprise in the United States, and many names might be given of those who do not use less than \$50,000 or \$25,000 for their yearly advertising. Some of the larger incorporated companies are also heavy advertisers. This is a peculiar feature in this country, as most of these interests are advertised in Europe by a brief card, if at all. The "Union Pacific Railway Company," and also the "Northern Pacific," are stated to have advertised to the extent of between \$400,000 and \$500,000 in a little over two years. Insurance companies expend large amounts in this way, and banking houses, brokers, and those connected with shipping interests, all find advertising advantageous. Nor are their advertisements confined to any single class of newspapers. When Jay Cooke advertised the bonds of the United States, his announcements were seen throughout the country. The banker's orders to his manager were, "Give the advertisement to all those newspapers that are alive enough to apply for it." The faith of Americans in advertising may best be shown in the fact that newspaper publishers and the largest advertising agents are often liberal advertisers. The sum of \$3,500 has been paid by "The Sun" for an advertisement in one number of a publication. The weekly paper which is supposed to have the largest circulation in the country, the "New York Ledger," gained it almost exclusively by advertising. In 1867 the government tax was collected on nearly \$10,000,000 worth of advertisements. New York state paid nearly \$100,000 tax, at 3 per cent. (of which the city alone paid over \$80,000), Philadelphia \$30,000, Boston \$23,000, Cincinnati \$16,000, Chicago \$15,000, and New Orleans and St. Louis each over \$13,000. In the five years 1867-'72 the amount paid by the public for their advertising must have reached \$15,000,000 annually. The use of pictures in the advertising columns of newspapers is gaining constantly in popularity, and less and less resistance is made to it by publishers. Of the 150 religious newspapers, most of which refused cuts two or three years ago, all but 16 now accept them.

ADVOCATE. See **LAWYER.**

ADVOCATUS DIABOLI, in the Catholic church, the speaker or writer who shows cause against the canonization of a person proposed for sainthood. The advocate who defends the proposed

saint is called *advocatus Dei*. The *advocatus diaboli* insists upon the weak points of the good man's or woman's life. Hence the name is sometimes popularly applied to those who detract from the characters of good men.

ADVOWSON, in English law, the right of presenting to a vacant living in the church. Advowson, according to Blackstone, signifies taking into protection or patronage. When the lord of a manor built a church and endowed it, he acquired a right of nominating the ministers, provided they were canonically qualified. Advowsons are property, and as such purchasable, provided that certain laws for the prevention of simony are not infringed in the purchase. These laws are, however, more frequently evaded than obeyed. The most ordinary form of advowson is the presentation of a duly qualified clergyman to the bishop for institution into the living. The bishop has the right to reject the candidate presented; but in a few rare cases the patron has a right of presenting a person without the bishop's interference. The benefices of the church of England are in every case subjects of presentation. They are nearly 12,000 in number; the advowson of more than half of them belongs to private persons, and of the remainder to the crown, bishops, deans and chapters, universities, and colleges. The incumbents are maintained by tithes, or since the tithes commutation act by taxes in lieu of tithes. The elective right of the congregation is unknown in the church of England, except in regard to those clergymen who perform duties in excess of the regular duties of the rector or vicar; such for instance as lecturers, who are paid by voluntary contributions.

ÆACUS, in Greek mythology, son of Jupiter and Ægina, and first king of the island of Ægina. He was renowned for his justice, so that he was called upon to settle disputes not only among men, but even among the gods. His reputation was such that, on the occasion of an excessive drought in Greece, he was appointed by the oracle of Delphi to intercede with the gods for rain, and his prayers were successful. After his death, Pluto made him one of the three judges of Hades.

ÆDILES (Lat. *ædes*, a building, temple). Roman magistrates charged with the supervision of public buildings, archives, streets, roads, aqueducts, markets, baths, eating houses, places of amusement, and public games; with the regulation of prices of provisions, and of weights and measures; with the sanitary superintendence, and various other functions of a similar character. The ædiles were originally of the plebeian order, and served as assistants to the tribunes of the people. Subsequently they became independent magistrates. In the earlier part of the 4th century B. C. two patrician ædiles were added, who enjoyed the double privilege of wearing the *toga prætexta* and sitting on curule chairs (*ædiles curules*). These privileges were soon after extended to their plebeian colleagues. In the latter periods of

the republic the office of ædile became an object of great ambition to wealthy politicians, who sought to win the favor of the multitude by lavish expenditures on the public games.

ÆDI, or **Hedui**, a powerful people of Celtic Gaul, between the Saône and the upper Loire, which rivers separated their territory from the countries of the Sequani and Bituriges. They were the first Gallic tribes which concluded an alliance with the Romans, and having, after a struggle with the Sequani, fallen under the power of Ariovistus, the German ally of the latter, were restored to power by Julius Cæsar, shortly after the opening of his Gallic campaigns (58 B. C.). They joined, however, in the great rising against that conqueror under Vercingetorix (52), on whose fall they were leniently treated by the victor. Their chief town was Bibracte, subsequently called Augustodunum, now Autun, in Burgundy.

ÆGEON. See BRIAREUS.

ÆGEUS, a legendary king of Athens, father of Theseus. Misled by a false signal to believe that his son had been killed in a contest with the Minotaur, he cast himself into the sea, which, according to some, was called after him the Ægean.

ÆGEAN SEA. See ARCHIPELAGO.

ÆGINA, or **Engia** (Turk. *Engia*), a Greek island in the Saronic gulf (now gulf of Ægina), 12 m. S. S. W. of the Piræus, about 9 m. long from N. E. to S. W., and about 7 m. wide. Its western side consists of stony but fertile plains, which are well cultivated and produce luxuriant crops. The rest of the island is mountainous. The climate is the most healthy in Greece. From its hills a magnificent prospect unfolds itself. Its chief interest depends on its past history and its antiquities, it having been one of the most celebrated islands of Greece, both in the mythological and historical periods, and also in the sphere of art. It was a Dorian settlement, and was one of the first places in Greece noted for its maritime ascendancy. As early as 563 B. C. Ægina had a factory in Egypt. It was a great rendezvous for pirates and slave traders, fugitive criminals and insolvent debtors. The people of Ægina, with their contingent of 30 ships, played a brilliant part in the great sea fight off Salamis. Its earliest enemy was Athens, which state eventually, in 429 B. C., took possession of the island and expelled its inhabitants. Ægina, though often mentioned in the Greek authors, never recovered any political or commercial importance. Sulpicius, in one of his letters to Cicero, in which he alludes to a cruise in the Saronic gulf, speaks of Ægina as a monument of departed greatness. Its chief temple was that of Zeus Panhellenius, or, in the opinion of some archaeologists, that of Minerva, mentioned by Herodotus. Cicero speaks of it as in ruins. In 1811 a company of German and British scholars cleared away the rubbish which had accumulated in the course of 2,000 years at the base of the temple, and after 20 days' excavat-

ing were rewarded by the discovery of 16 statues of an early type of Greek sculpture. These statues are now in the Glyptothek of Munich, and have been restored by Thorwaldsen. The subject is supposed to be the expedition of the Æacidae or Æginetan heroes against Troy, under the guidance of Minerva. The present population of the island is about 6,000, and that of its chief town, of the same name, on the W. side, near the ruins of the ancient town, 3,000. The products are wine, oil, fruits, and grain. The Ægina almonds are the best in Greece. The water works on the neighboring Mount Elias, famous for its magnificent views, save the island from drought. A bishop resides on the island, and schools and churches abound. Since the decay of the Byzantine empire, Ægina has been successively in the hands of the Venetians, Turks, and Greeks. Under Capodistria it was from 1828 to 1831 the seat of the government. Edmond About has published *L'Île d'Égine* (1854).

ÆGIS (Gr. *αἴς*, she goat), the appellation of the shield of Jupiter, which was covered with the skin of the goat Amalthea, by which that god was nourished in infancy. Minerva also bore an ægis, which, at least according to post-Homeric mythology, was of different origin.

ÆGISTHUS, king of Mycenæ, son of Thyestes and cousin to Agamemnon. He formed an adulterous connection with Agamemnon's wife Clytemnestra during his absence at Troy, and contrived his murder on his return. Eight years later he was slain by Orestes, the son of Agamemnon. Writers later than Homer tell a frightful story of incest and crime about Ægisthus and his family. (See **ATREUS**.)

ÆLIA CAPITOLINA, a name given to Jerusalem by the emperor Hadrian (Ælius Hadrianus), who, after a rebellion of the Jews in his reign, drove them from the destroyed city and its environs, and repeopled it with Roman colonists. It went by this title until the time of the Christian emperors.

ÆLIANUS, Claudius, a writer of the early part of the 3d century, born at Preneste in Italy. His compilation, generally known under the Latin title *Varia Historia*, is still extant, as well as an original treatise *De Animalium Natura*. These works are written in Greek, of which the author, though an Italian by birth, was a perfect master.

ÆELST, or Aalst, a town of Belgium. See **ALOST**.

ÆELST, or Aalst. **I.** Evert van, a Dutch painter, born in Delft in 1602, died in 1658. He was distinguished for painting flowers, dead birds, and game, and other inanimate objects. Few of his works are to be found in picture galleries. **II.** Willem van, nephew and pupil of the preceding, born in Delft in 1620, died in Amsterdam in 1679. His works in the same line were more admired than those of his uncle, and are to be found in the galleries of Berlin, Munich, and Dresden, as well as in France and Italy, in which countries he spent many years,

particularly in Florence. In the coloring, finish, delicacy, and naturalness of his flowers and fruits painted on vases, he had no superior.

ÆMILIUS PAULUS. **I.** See **PAULUS**. **L. ÆMILIUS**. **II.** (PAOLO EMILIO), an Italian historian, born in Verona, died in Paris, May 5, 1529. In consequence of his celebrity as a writer in Italy, Louis XII. made him a canon of the cathedral of Paris, and employed him to write a history of the kings of France in Latin.

ÆNEAS, son of Anchises and Venus, a Trojan prince, with whom tradition connects the origin of the Roman empire. Having fought for Troy till it fell, he quitted the burning city with his followers, accompanied by his father and son. After visiting various countries, they landed on the shores of Latium, where they met with a friendly reception from King Latinus. They settled there, and soon became involved in hostilities with the people of the country, in the course of which Latinus was slain. Æneas was finally victorious. He married Lavinia, the daughter of Latinus. His son by Creüsa, Ascanius or Iulus, founded Alba Longa, one of the last kings of which, Numitor, was the grandfather of Romulus and Remus, the founders of Rome. Æneas is the hero of Virgil's Æneid.

ÆNEAS SILVIUS. See **PITRUS II.** (pope).

ÆNEID. See **VIRGIL**.

ÆLIANES, an ancient tribe of upper Greece, of remote and uncertain origin, whose frequent migrations in early times are spoken of by many writers of antiquity, especially by Plutarch, in his "Greek Questions." According to this author, they occupied in the first instance the Dotian plains, on the confines of Thessaly and Macedonia, moved thence into Epirus, and in their last migration went from Crissa, on the gulf of the same name, to the valley of the northern Inachus, on which they finally settled. Their chief town was Hypata, at the foot of Mt. Æta, of which considerable remains exist at the village of Neopatra. The antiquity and early importance of this people are attested by the fact of their belonging to the Amphictyonic council. At a later period they joined the confederation of the other Hellenic states against Macedonia, which gave rise to the Lamian war; but according to Strabo, in his time they had no longer a national existence, having been nearly exterminated by the Ætolians and Athamanians.

ÆOLIAN HARP, a musical instrument, the tones of which are produced by the sweeping of the wind over its strings. Its invention is ascribed to Athanasius Kircher. It is composed of a rectangular box made of very thin boards, about 5 inches deep and 6 inches wide, and long enough to fit across the window in which it is to be placed. At the top of each end of the box is glued a strip of wood about half an inch in height; these strips serve as a bridge for the strings, which are stretched lengthwise across the top of the box, and are made of catgut or wire. These strings should

be tuned in unison by means of pegs constructed to control their tension, as in the violin. When the instrument is exposed in a window

Æolian Harp.

partly open, so as to allow a current of air to pass over the strings, a most agreeable combination of tones is produced, constantly varying in pitch and intensity with the force of the wind, and forming harmonies of a wild and melancholy character.

ÆOLIAN ISLES. See LIPARI ISLANDS.

ÆOLIANS, the name of one of the primitive divisions of the Hellenic race. They are said to have dwelt originally in the S. W. part of the plain of Thessaly, and thence to have spread over other regions of Greece, and after the Doric invasion of the Peloponnesus to have occupied the N. W. coast region of Asia Minor, from them called Æolis, and the islands of Lesbos and Tenedos. Of the Æolic dialect of the Greek, which was chiefly developed in Lesbos, only scanty specimens have been preserved; these bring it nearer to the Doric than the Attic. Mythologically, the Æolians were descended from Æolus, the son of Hellen.

ÆOLIPYLE, or **Æolipile** (*Αἰόλον-πύλαι*, the gate of Æolus; or, more probably, *Æolipila*, the ball of Æolus), a hollow metallic ball, containing a curved tube connected with a small orifice, and sometimes two such tubes turning in opposite directions. Water or alcohol being introduced in it and boiled, it was used in old times to exemplify the force of steam, or as a blowpipe when adjusted to a lamp. In 1615 Salomon de Caus noticed in using it the effect of steam in causing water, by the assistance of heat, to mount above its level. This machine was intended to discover the cause of the winds.

ÆOLIS, in ancient geography, a district in Asia Minor, originally settled by colonies of Æolian Greeks. It was properly the coast land of Mysia, extending from Troas to the south bank of the river Hermus. In its broadest signification it included Troas to the shores of the Hellespont. In the southern part were situated the twelve cities which formed the Æolian league. Of these, Cyme, where the annual Panæolium was celebrated, and Smyrna, which in later times became a member of the Ionian confederation, were the most celebrated.

ÆOLUS. I. In Greek mythological history, a son of Hellen, who, in the division by the

latter of the government of the Hellenes or Greeks between him and his brothers Dorus and Xuthus, received the throne of Thessaly and named his subjects the Æolians. He was the progenitor of a great race of heroes, the Æolids, from whom in turn sprang many of the most famous personages of the Greek legends. Other genealogies were also given by the Greeks to Æolus, but the above, that of the Hesiodic catalogue, is that which Grote believes to have been generally received. II. An inferior god or demigod, ruler of the winds. There seems no good reason to connect this Æolus with the preceding, but a few Greek authors endeavored to prove even the identity of the two, while others made the demigod the son of Jupiter and Acasta, daughter of Hippotas. Æolus was supposed to have his home in the island now called Stromboli, of the Lipari group, anciently known as the Æolian islands. According to tradition, he kept the several winds confined in bags, releasing them at the command of Neptune.

ÆON, a Greek term signifying age. In Gnostic speculations, æons are embodiments of divine attributes. (See GNOSTICS.)

ÆPINUS. I. **Johann** (the Greek translation of his real name, *Hoch* or *Höck*, high), a German theologian, born at Ziegesar, Brandenburg, in 1499, died in Hamburg, May 13, 1553. He studied at Wittenberg, was arrested on account of his zeal for the cause of Luther, and exerted himself after his release in England and Germany on behalf of the reformation. He was afterward for some time teacher at Stralsund, and organized the new educational and ecclesiastical system there, and in Hamburg (1522), in which latter city he was pastor, and afterward superintendent of St. Peter's church from 1529 till his death. He was one of the signers of the Smalcald articles in 1537, shared in the theological controversies regarding the Interim, the Adiphora, and the doctrines of Osiander, and was supported by Flacius and others, and to a moderate extent also by Melancthon. II. **Franz Ulrich Theodor**, a German physicist, a descendant of the preceding, born at Rostock in December, 1724, died in Dorpat in 1802. He became professor of physics and member of the academy of sciences at St. Petersburg in 1757. Catharine II. appointed him teacher of her son Paul, director of the nobility corps of cadets, and inspector general of the normal schools which she projected. He is honored as the inventor of the electrophorus and of electric condensation, an improver of the microscope, and the discoverer of the electrical polarity of tourmaline. He contributed extensively to the publications of the Berlin and St. Petersburg academies. His principal work is *Tentamen Theoriæ Electricitatis et Magnetismi* (St. Petersburg, 1759; French translation, abridged by Haüy, 1787). One of his other works, written in German, was translated in 1762 into French by M. Raoult, under the title of *Réflexions sur la*

distribution de la chaleur sur la surface de la terre. He wrote in French *Description des nouveaux microscopes inventés par M. L'Épinus* (St. Petersburg, 1786).

ÆQUI, also called **Æquicoli** and **Æquiculani**, an ancient warlike people of central Italy, dwelling in the mountainous region of N. E. Latium, between Lake Fucinus (Lago di Celano) and the Anio (Teverone), surrounded by the Sabines, Marsi, Hernici, and Latins. They were among the most obstinate enemies of the early Romans, fighting them chiefly in alliance with the Volsci, a kindred people, and together with the latter were badly defeated by Camillus in 389 B. C. They suffered still more crushing defeats shortly before the close of the same century, when they were finally subdued. Mount Algidus, in the western part of their territory, was one of their natural strongholds, from which they made their incursions into the country around Rome.

ÆRIANS, a semi-Arian sect of the 4th century, named from Ærius, a monk of Pontus, and holding middle ground between the Arians and the Nicæans. The Nicæans were Homoiousians, and the high Arians were Heterousians, while the Ærians were Homoiousians. The Ærians in church government denied the distinction between a bishop and a presbyter. They were opposed by a small counter faction called Ætians. (See **ÆTIRIS**.)

ÆRÖE, or **Ärröe**, an island belonging to the Prussian province of Schleswig-Holstein, in the Baltic, E. side of the entrance to the Little Belt, 10 m. S. of Fünen; pop. 12,400. It is about 10 m. long by 5 broad, and is fertile and well cultivated. The capital, Aeröeskjöbing, has considerable shipping; pop. 1,700.

ÆROKLINOSCOPE, an instrument recently introduced on the continent of Europe, in connection with the weather signal departments. It is intended to give public information of the condition or rather differences of barometric pressure at the different stations, so that every one at a glance may see in what quarter the maximum and minimum barometric pressure is, and consequently what direction of wind and what kind of weather are to be expected. The apparatus as now in practical use consists of a vertical axis some 30 feet high, turning on a pivot, and carrying on its top a horizontal arm of which the inclination can be varied according to the difference of barometrical pressure at different sides of the station. If the pressure is the same north and south, for instance, the horizontal arm is placed horizontal; but if the pressure is less in the north, the northern end of the arm is caused to dip downward, and more so in proportion as the barometer is lower north as compared with its position south. The amount of dip is regulated by a sliding rod, held in position by different notches at the lower part of the axis, each notch corresponding with one millimetre in barometric pressure. This most useful apparatus is the invention of Buys-Ballot in Holland.

The government of the Netherlands introduced storm signals there in 1860; England followed in 1861, and France in 1863.

AËROLITE (Gr. *ἀήρ*, air, and *λίθος*, stone), a stone or mineral mass of ultra-terrestrial origin which has fallen to the earth. The different bodies constituting our planetary system vary considerably in size. Jupiter, the largest, has in round numbers a diameter of 80,000 miles, while Clio, the smallest of the so-called asteroids thus far known, has a diameter of scarcely 16 miles, and is thus 125,000,000 times smaller in bulk. There is no ground whatsoever to assert that Clio is the smallest body which revolves around the sun; most likely there are bodies as much smaller than Clio as the latter is smaller than Jupiter. Such bodies would have a diameter of scarcely 16 feet; and if we descend another step in the same ratio, we come to bodies of a diameter of $\frac{1}{2}$ of an inch, constituting mere dust. Such bodies may revolve in myriads in the planetary space, without our ever being able to obtain any knowledge of their existence, except where they come so near to our planet as to be acted on by its gravitation and drawn to its surface. It has been proved by the statistics of observation that every year 600 or 700 meteoric showers take place over the surface of our earth, bringing down at least 5,000 separate aërolites; the unequal distribution over different portions of the earth's surface is only apparent, as the two zones in America and Europe in which, according to Prof. Shepard the greatest numbers of meteoric showers have been observed, are simply those zones which are the most thickly peopled, and where the press and telegraph diffuse rapidly every observation. Sometimes one or two single masses fall, and sometimes a shower of 2,000, 3,000, or more stones is distributed over a surface of several acres or even miles; sometimes dust accompanies the shower, and sometimes dust falls alone. The theory here propounded is due to Chladni, who toward the end of the last century defended the idea originated by Kepler, that there were more comets and smaller bodies flying about in space than fishes in the ocean. Before Chladni's time the most absurd ideas prevailed in regard to the origin of aërolites. Some supposed that they were formed in the upper strata of our atmosphere by the condensation of vapors of solids, as hailstones are formed by the condensation and congelation of watery vapors. Laplace sought their origin at a greater distance, and concluded that as gravitation on the moon is about four times less than it is on the earth, it might be possible that the volcanoes there project stones with such force as to go beyond the limits of lunar attraction, and to reach that of the earth; and indeed a velocity two or three times greater than that which we are able to give to a cannon ball would accomplish this result. These theories prevailed for a time, although chemists proved that aërolites are

not of volcanic origin, and astronomers proved that their velocity in approaching the earth is far too great to be accounted for by terrestrial attraction. Mechanical science indeed proves that a body falling from an infinite distance will arrive at the earth with a velocity of only 6 to 7 miles per second, while aërolites pass tangentially through our atmosphere with more than double or triple that rate, in fact, with a planetary velocity; some of them even overtake the earth in its course, as is the case with those falling about sunset. By the combined rotation and revolution of the terrestrial globe, that portion of the earth where it is sunset moves from its zenith, while that portion where it is sunrise moves toward its zenith, or at least toward that portion of the zodiac nearest to its zenith, and thus has more chance of coming in contact with isolated flying masses; this accounts for the fact that the greatest number of aërolites fall in the forenoon. Of the cases recorded in history, the most remarkable are as follows: An aërolite is mentioned by Pliny, which fell in 467 B. C. in Thrace, and was still extant in his time; he states that it had the size of a wagon. The Chinese chronicle a large aërolite which fell during a thunderstorm long before our era. The *Annales Fuldenses* report a great shower of aërolites in Saxony in 823, by which men and cattle were killed and 35 villages were set on fire. Among the other cases, the most remarkable are the falls of aërolites in 921, 1010, 1164, and 1304, all in Europe. In Alsace there fell in 1492 an aërolite of 260 lbs., which is still preserved in the church of Ensisheim. In Crema a shower of many hundreds of stones took place Sept. 14, 1511; 1,200 pieces were collected, of which one weighed 260 lbs., and another 120 lbs. Records of later date become more and more complete and authentic, and all doubts in regard to the accuracy of their statements, existing till the end of the last century, were removed when, on April 26, 1803, at Aigle in France, a small immovable cloud was seen, out of which, during explosions lasting five to six minutes, a number of stones fell on a surface two miles long. The largest weighed 20 lbs., the smallest $\frac{1}{4}$ ounce. On March 13, 1807, an aërolite of 140 lbs. fell in Smolensk, Russia; and on May 22, 1808, at Stannern in Moravia, between 200 and 300 stones fell, from half an ounce to 11 lbs. in weight. An American vessel 240 miles S. of Java experienced on Nov. 14, 1856, a shower of stones of the size of shot, which were afterward proved not to be the product of the eruption of a distant volcano, carried along with the winds, as at first suggested, but of true cosmical origin—a question easily settled by the microscope and chemical analysis, as will be seen later. Klein published in his *Sonnensystem* (Brunswick, 1869) a record of more than 300 well authenticated cases, of which 3 were in the 15th century, 15 in the 16th, 23 in the 17th, 40 in the 18th, and 216 in the first 69 years of the 19th

century. It is certain that such falls were just as frequent in former centuries as they are now, only the records are lacking. In regard to the ancient geological eras, there is no doubt that the falls of meteoric masses were even more frequent; it is highly probable even that a portion of the earth's and moon's mass is largely made up of such aërolites, which are not now found in the lower strata of the earth for the simple reason that they are very oxidizable, and have been disintegrated by air and water and mixed with the original terrestrial matter, by the immense changes through which our earth's crust has passed; they may therefore exist in a better state of preservation on the moon's surface. Olbers supposes that the earth has during countless ages hollowed out for itself a kind of comparatively empty rut among those flying aërolites, attracting all within the reach of its gravitation, and that now, by the periodical inequalities and perturbations of its orbit, it occasionally appropriates some masses which had before escaped its attractive power, or that the earth occasionally comes in the neighborhood of masses having an orbit which intersects its own. (See METEOR.) In regard to the sizes, the largest masses on record were heard of by Capt. Ross in 1818, when the Esquimaux of Baffin bay informed him of their existence on the W. coast of Greenland. They were found in 1870 by the Swedish Arctic expedition, which brought some of them to Stockholm, where they excited so much interest that in 1871 20 more specimens were collected, now in the royal academy of Stockholm, the largest weighing 25 tons, with a maximum sectional area of 42 square feet. The next in size weighs 10 tons, and has been presented to the museum of Copenhagen. In Mexico and Brazil similar masses have been found. The British museum possesses one of more than five tons. In the museum in St. Petersburg is a mass of 1,680 lbs. found in Siberia in 1772. Yale college, New Haven, possesses, among more than 100 specimens, one aërolite of 1,635 lbs., which fell in Texas in 1808. The Smithsonian institution possesses a very remarkable annular specimen discovered about 1700 in Mexico, which, according to an Indian tradition, fell there about 200 years before during a shower of stones; its weight is 1,400 lbs. Aërolites of a weight of 200 to 400 lbs. are not uncommon in collections, and those of 100 lbs. and less are very common.—In regard to the chemical composition of these stones, it must be observed that in passing through our atmosphere they undergo some change, as they always take fire in the upper regions, and arrive at the ground quite hot, sometimes making a deep hole. Combustible substances in their composition, and perhaps an atmosphere of combustible gases surrounding them, combined with the immense velocity with which they enter our atmosphere, cause on the sudden diminution of that motion a most intense rise of temperature, ignition.

and very often one or more exceedingly violent explosions. It is therefore not surprising that they all present the appearance of having been subjected to great heat. Chemical analysis has shown that there are two principal kinds, the stony and the metallic aërolites, which by further investigation have been divided into several groups, in accordance with the elements contained and the character of their combinations. Stony aërolites resemble the peridot, a universal scoria from the earth's deep interior, underlying the aluminous basic rocks, the granite and gneiss; the latter, being stratified rocks, are never found among aërolites. The specific gravity of stony aërolites is 3.5 to 3.8, while that of stratified formations, gneiss and granite, and of lava, is only 2.6 to 2.9. Metallic aërolites have a specific gravity of from 6.5 to 8, and consist chiefly of iron, always combined with nickel, usually containing 60 per cent. or more of iron and 5 to 25 of nickel, a compound never found on earth; the other elements are chiefly phosphorus, silicon, aluminium, cobalt, and manganese. Other substances which have been found in different specimens are: magnesium, titanium, tin, copper, chromium, arsenic, calcium, potassium, sodium, sulphur, carbon, chlorine, nitrogen, and hydrogen in occlusion (see ABSORPTION OF GASES BY SOLIDS), making 22 elements, one third of those of which the earth is composed. Some aërolites are of a mixed stony and metallic character, but they are never homogeneous; even the metallic ones, which appear to be an alloy, are very heterogeneous. This is manifested by grinding and polishing a face and then acting on it with nitric acid, when some portions will dissolve, and more resistant small crystals will become prominent, showing a decided crystalline structure. The figures thus formed are called, after their discoverer, Widmannstaett's figures, and they may be made so prominent as to allow the surface to be used as an engraved plate and printed. Our figure represents an aërolite found in Wisconsin, preserved in the

Widmannstaett's Figures.

cabinet of I. A. Lapham of Milwaukee, and engraved after the photograph of a section prepared by Dr. J. Lawrence Smith, showing the Widmannstaettian figures.—The idea suggested by Sir William Thompson before the British association for the advancement of science in 1871, that the existence of vege-

table and animal life on our planet may be accounted for by aërolites having brought the first organized germs hither, substitutes for the difficult question as to the terrestrial origin of organisms, the still more perplexing one of how they originated on the aërolites.—See further Phipson's "Treatise on Meteors, Aërolites, and Falling Stars" (London, 1866); Daubrée, *Rapport sur les progrès de la géologie expérimentale* (Paris, 1867). The latter is very exhaustive, and contains accounts of experiments in imitating the different kinds of aërolites.

AËROMETER (Gr. *ἀήρ*, air, and *μέτρον*, measure), an instrument invented by Dr. Marcus Hunt for ascertaining the mean bulk of gases and the density or rarity of air. It is now little used, and the whole doctrine of air, considered as a fluid, its pressure, elasticity, rarefaction, and condensation, belongs in that department of natural philosophy termed pneumatics.

AËRONAUTICS (Gr. *ἀήρ*, air, and *ναυτικός*, of or belonging to ships), or **Aerostation** (Gr. *ἀήρ*, and *στάσις*, standing), the art of sailing in and navigating the air, and of raising and sustaining substances by means of gases specifically lighter than the atmosphere, contained in a spheroidal bag called a balloon. The former term is the more comprehensive of the two, and includes the whole science of aërial navigation, while the latter is generally confined to ballooning. The myths of Dædalus and Icarus show that the attempts of man to soar above the earth commenced in prehistoric times. Flying machines were expected to effect this object. Archytas of Tarentum is said to have manufactured, 400 years B. C., a wooden pigeon which sustained itself in the air a few minutes. Simon Magus, according to Suetonius, met his death in Rome in the reign of the emperor Nero in an attempt to fly from one house to another. Roger Bacon had some notion of a flying machine to be propelled by a system of wings; and in the latter part of the 15th century Dante, a mathematician of Perugia, rose above Lake Trasimene by means of artificial wings attached to his body. Many similar attempts have been made since then by persons imperfectly acquainted with the principles of mechanical philosophy, which have invariably resulted in failure, and the problem is as far from solution as ever. The discovery of the properties of hydrogen gas by Cavendish in 1766 gave the first hint of a practical method of aërial navigation. This is the lightest of the gases, being a little more than 14 times rarer than atmospheric air; and as early as 1767 Professor Black of Edinburgh announced to his class that a vessel filled with it would naturally rise into the air. A few years later (1782) Cavallo made a series of experiments on the subject, but did not succeed in raising anything heavier than a soap bubble. The honor of preparing and sending up the first balloon belongs to the brothers Stephen and Joseph Montgolfier, paper manufacturers at Annonay, near Lyons, who, however, at the outset of their experi-

ments, knew nothing of hydrogen gas, and employed heated air to inflate their machine, without apparently being aware of its superior buoyancy to the atmosphere. Their balloon was constructed of linen cloth lined with paper, under which a fire was kindled, fed with bundles of chopped straw. By this means dense volumes of smoke were produced, which filled the balloon; and it would seem that they actually expected the latter to be raised by the ascending power of the smoke, instead of its true cause, the rarefaction of the heated air.

First Balloons made by Montgolfier.

On June 5, 1783, their balloon, weighing 500 pounds, first rose into the atmosphere. It reached an altitude of nearly a mile, remained suspended a few minutes, and, as the air escaped, gradually returned to the earth. The event singularly impressed all classes of society, and the most extravagant notions were entertained of the uses to which balloons might be applied. Several successful ascents were made within the next few months from Paris, and on Nov. 21, 1783, Pilâtre de Rozier and the marquis d'Arlandes, the first adventurers who durst ascend in an unconfined balloon, astonished the world by rising to the height of 3,000 feet, descending in safety not far from Paris. These experiments were mostly made with the Montgolfier balloon, or *montgolfière*, which was inflated with heated air, and the early aëronauts were obliged to carry with them a supply of fuel to renew the rarefied air as fast as it escaped. This clumsy and dangerous expedient subsequently led to disastrous results. On Dec. 1 of the same year Messrs. Charles and Robert left Paris in a hydrogen balloon, in the presence of 600,000 spectators, and after a trip of two hours descended in safety near Nesle, 25 m. distant. M. Charles immediately reascended alone, and had the satisfaction of seeing the sun, which had set when he left the earth, rise and set again. He descended in safety in 35 minutes, 9 m. from his starting point. In this expedition the fall of the barometer and thermometer was first noticed. The first, sinking to 20.05 inches, indicated an ascent of about 9,700 feet. The thermometer sank to 21° F. In 1784 upward of 52 balloon ascents are recorded, the most remarkable being those of Messrs. Charles and Robert, who reached an altitude of 13,000 feet; of Blanchard, the first aërial voyager by

profession; and of Prince Charles de Lignes. In January, 1785, Blanchard and Dr. John Jeffries, of Boston, accomplished the daring feat of crossing the channel from Dover to France, narrowly escaping being wrecked in the sea. In the same year occurred the first fatal accident connected with ballooning. Pilâtre de Rozier attempted, with a young man named Romaine Lainé, to cross from France to England in a hydrogen balloon, under which was suspended a small *montgolfière* for the purpose of increasing or diminishing the ascensional power at pleasure. The hydrogen, by its expansion in the rarer upper strata of the atmosphere, pressed down through the tubular neck of the balloon, and reaching the fire of the *montgolfière* was at once ignited. Both balloons were quickly consumed, and the voyagers were precipitated from a height of 3,000 feet upon the rocks near the French coast. As this calamitous occurrence was occasioned by the neglect of proper precautions, aëronauts were not deterred by it. Ascents to the number of many thousands have since been made in Europe and America, both in *montgolfières* and gas balloons, and it is believed that not more than 25 persons have lost their lives in consequence. Of this number of ascents, however, few only have been undertaken for scientific purposes, most having been made merely as a popular spectacle or for the sake of amusement. In this regard both hemispheres have furnished skilful and daring aëronauts. Among the earlier French voyagers was Blanchard, who died in 1809, having made more than 66 ascents, one of which took place in New York in 1796. Mme. Blanchard sometimes accompanied him, and after his death she occasionally ascended alone. In 1819, having ascended from Tivoli garden in Paris with some fireworks, her balloon became accidentally ignited and she was precipitated to the earth and dashed to pieces in the rue de Provence. In later times Eugène and Louis Godard have been the most famous of the French professional aëronauts. Green, the English aëronaut, had probably more experience in the management of balloons than any person who has given attention to the subject. During his professional career of 36 years, ending in 1857, he made nearly 1,400 ascents, crossing the sea three times and falling into it twice. His most interesting voyage was undertaken in 1836, when in company with Messrs. Holland and Mason he journeyed, in a balloon of great dimensions and provisioned for a fortnight, from London to Weilburg, in the duchy of Nassau, a distance of 500 m., in 18 hours. This feat of aërial travelling was however surpassed by Mr. John Wise, the American aëronaut, who with Mr. John La Mountain and two others passed in July, 1859, from St. Louis, Mo., to Henderson in Jefferson co., N. Y., a distance of 1,150 m., in 19 h. 50 m., or at an average speed of nearly a mile per minute. In September of the same year Messrs. La Mountain and Lowe made a voyage of 300 m. in about 4

hours.—The first ascent for the purposes of science was made from Hamburg on July 18, 1803, by Messrs. Robertson and Lhoëst, under the direction of the Russian academy of sciences. A second voyage followed in the succeeding month, and a third from St. Petersburg on June 30, 1804. But although the explorers reached on one occasion an altitude of 23,526 feet, no important results were obtained. In 1804 Laplace proposed to the French academy the solution, by means of observations from a balloon, of certain physical problems, and notably that of magnetic intensity at great heights. Gay-Lussac and Biot undertook to make the observations, and on Aug. 23 ascended from Paris to the height of 13,000 feet. Their experiments in magnetism, electricity, and galvanism gave results identical with those made on the earth. The rotatory motion of the balloon having presented an unexpected obstacle to careful observations, Gay-Lussac supplied his balloon with long hanging ropes destined to counteract this movement, and on Sept. 15 reascended alone to a height of 23,000 feet, and found a decline of temperature from 82° to 15°, which almost confirmed the theory of a fall of 1° in every 300 feet of elevation. The sky was very blue and the air was found to be very dry. A magnet took a longer time to vibrate than on the earth. He was the first to bring down air collected at this enormous height, which on being analyzed was found to be in its component parts the same as the lower air. In the highest strata of air reached by the balloon he suffered severely from cold. Breathing was difficult, the pulse and respiration were much quickened, and the throat became parched. In 1806 Carlo Brioschi, the astronomer royal of Naples, in company with Andreani, the first Italian aéronaut, attempted to rise from Naples to a greater height than that attained by Gay-Lussac; but in consequence of the bursting of the balloon the explorers were precipitated to the earth, which they fortunately reached without material injury. No subsequent scientific aerial expeditions took place till 1850, when Messrs. Bixio and Barral ascended from the garden of the observatory in Paris in a balloon filled with pure hydrogen gas. They reached a height of 19,000 feet, when an accident to their balloon compelled them to descend without having had the opportunity to make observations of much value. In a second ascent in July of the same year, they reached a height nearly equal to that gained by Gay-Lussac in his second expedition in 1804, but, owing to a tear in their balloon, were unable to rise above a bank of cloud estimated to be 15,000 feet in thickness, and reach the blue sky beyond. The most extraordinary phenomenon noted by them was the sudden variation of temperature during the last few thousand feet of their ascent. At the height of 19,000 feet the thermometer marked 15°, but in the next 2,000 feet it fell to 39° below zero, thus showing a temperature lower by

54° than that noted by Gay-Lussac at a similar elevation. In 1852 Mr. Welsh, of the Kew observatory, in company with Mr. Green, made four ascents from London in the great "Nassau" balloon, with results tending to confirm those already recorded by Gay-Lussac.—The most remarkable and successful ascents ever made for scientific purposes were those of Mr. James Glaisher, F. R. S., from various parts of England in 1862-'6, and of Messrs. Camille Flammarion, W. de Fonvieille, and Gaston Tissandier from Paris and other parts of France in 1867-'9. On Sept. 5, 1862, Mr. Glaisher, accompanied by Mr. Coxwell, an experienced aéronaut who had already made 400 ascents, reached the astounding height of 37,000 feet, or 7 m. above the earth's surface. At the height of 5½ m. Mr. Glaisher gradually lost the use of his limbs, and finally became totally insensible. Mr. Coxwell had meanwhile climbed up to the ring of the balloon in order to free the valve rope, which had become entangled; while doing this his hands became frozen and powerless, and he was compelled to drop down into the ear and pour brandy over them to restore the circulation. He then perceived the critical condition of Mr. Glaisher, and endeavored to approach him; but finding himself also in danger of lapsing into insensibility, and being at the same time without the power to move his hands, he seized the valve rope with his teeth, dipped his head downward several times, and found to his relief that the escape of gas caused the balloon to descend rapidly into a warmer temperature. Mr. Glaisher soon after revived, and they returned without further adventure to the earth. The results of Mr. Glaisher's observations induced him to abandon the theory of a decline of 1° of temperature for every increase of 300 feet of elevation. M. Flammarion calculated a mean abatement of 1° for every 345 feet when the sky is clear, and of 1° for every 354 feet when the heavens are overcast; but Mr. Glaisher's midday experiments show that within the first 1,000 feet from the earth the average space passed through for a decline of 1° was 223 feet with a cloudy sky, and 162 feet with a clear sky. Above 10,000 feet the space passed through for a like decline was 455 feet for the former, and 417 feet for the latter; and above 20,000 feet the space with both states of the sky was nearly 1,000 feet for a decline of 1°. In an ascent made by him on July 17, 1862, the temperature was 59° at the surface; at 10,000 feet it had fallen to 26°, and at 20,000 feet it had risen to 42°, which shows a difference of 81° from the temperature recorded by Bixio and Barral at the same altitude in their second ascent in 1850. Notwithstanding the difficulty of extracting any definite law from such capricious data, the results of Mr. Glaisher's observations above quoted afford a much nearer approach to a solution of the problem than the old rule of a uniform rate of decrease. All aéronauts have been aware of the existence of atmospheric currents, often

moving in opposite directions, to which they are obliged to trust themselves, if desirous of travelling in a horizontal direction. M. Flammarion made the curious discovery that the traces of his various voyages are all represented by lines tending to curve in one and the same general direction; whence he concluded that above the soil of France the currents of the atmosphere are constantly deviated circularly, and in a south-west-north-east-south direction. Still more curious was the discovery by Mr. Glaisher of what may be called an aerial gulf stream. In his ascent of Jan. 12, 1864, he reached a warm current at a height of 1,300 feet. At 3,000 feet the temperature was 45° , being $3\frac{1}{2}^{\circ}$ warmer than at the surface, and for the next 3,000 feet it was higher than on the earth. It then gradually fell to 11° at 11,500 feet. This warm stratum of atmosphere was a current moving from the S. W. in the direction of the gulf stream. Fine granular snow was falling into it. The existence of this warm S. W. current goes far, Mr. Glaisher thinks, to explain why England possesses a winter temperature so much higher than her latitude would indicate. The same observer found that the time of the vibration of a magnet was greater than on the earth; that the number of pulsations and inspirations increased considerably at the higher elevations, although the same individuals were differently affected at different times; that the velocity of the wind was much greater at a high elevation than near the surface; and that sounds from the earth were more or less audible according to the amount of moisture in the air. When in the clouds at 4 m. high he heard a railway train; but when clouds were below, no sound ever reached the ear at this elevation. The barking of a little dog was heard at the height of 2 m., while a multitude of people shouting was not heard at 4,000 feet. At the greatest heights to which Mr. Glaisher ascended he found that the color of the unclouded sky deepened to an intense prussian blue when the air was free from moisture. He rejects the theory which ascribes this to reflection from vesicles of water, and concludes that it must be caused by reflection from the air, whose polarizing angle is 45° .—Soon after the invention of balloons the idea was entertained that they might be used to advantage in war for purposes of observation and reconnoissance. An aërostatic school was established at Meudon in France, and a number of balloons were distributed among the French army. At the sieges of Maubeuge, Charleroi, Mannheim, and Ehrenbreitstein they proved to be of some value. It is said that the battle of Fleurus was gained by Gen. Jourdan in 1794 mainly through information of the Austrian positions and movements communicated by French officers stationed in a balloon. The machine was held by a cable, but its tether was easily extended by means of a windlass, so that the observers could soar above the enemy's fire.

This is the last we hear for many years of the use of balloons in warfare. In the Italian campaign of 1859 they were again employed by the French, and one is reported to have aided them effectually at the battle of Solferino. Early in the American civil war (1861-'5) a balloon corps was organized by the United States war department, in the management of which Messrs. La Mountain, Lowe, and other experienced aëronauts were associated. Mr. Lowe first performed the feat of telegraphing from an aerial station 600 feet above the earth. In the summer and autumn of 1861 many balloon reconnoissances were made along the Potomac and in the neighborhood of Fortress Monroe. The balloon corps formed a part of Gen. McClellan's expedition to the peninsula in the spring of 1862, and when his army in May and June occupied the lines in front of Richmond, the balloons were brought into daily use for purposes of observation. On one occasion, while Gen. Fitz-John Porter was watching the movements of the enemy from a captive balloon, the cable broke, and he was carried over the confederate lines. By pulling the valve string he caused the machine to descend, when it struck a current of air going in the opposite direction, and he landed safely within the Union lines. During the two days of the battle of Fair Oaks Mr. Lowe watched the conflict from an elevation of 2,000 feet, and was the first to announce the enemy's retreat to Richmond. After the retreat of McClellan to Harrison's Landing the balloon corps seems to have been disbanded, and no subsequent employment of the balloon for military purposes is recorded during the war. At the commencement of the Franco-Prussian war of 1870-'71 a proposal was made to Marshal Leboeuf that the French army should be supplied with balloons, but he rejected it. A similar proposal was made to the German war department, which was accepted, but failed because the balloons were placed in unskilful hands. The siege of Paris by the Germans in 1870-'71 gave a new and unexpected impulse to the science of aërostatics. Toward the close of September, 1870, the city was completely invested, and the balloon, rejected by the French government as of no practical use a few months previous, was gladly employed by the besieged as a means of communicating with those parts of the country not under the control of the enemy. As no machine in the city was at that time considered sufficiently trustworthy to pass over the besieging lines in safety, balloon factories were established in two of the principal railway stations, which previous to the capitulation turned out nearly 70 machines. The material of the envelope was calico varnished on the exterior with a mixture of linseed oil and oxide of lead, and the network, car, and other appurtenances were of the customary pattern. The balloons were of an average capacity of 70,000 cubic feet. The first left Paris Sept. 23 with 227 pounds

of letters, and descended at Evreux. From that date to the end of the siege, Jan. 28, 1871, 61 others were despatched. Of these, 54 were sent by the post office department, carrying about 2,500,000 letters, which represented a total weight of nearly 10 tons. Most of them also took carrier pigeons intended to bring back news and replies to the outgoing letters. Comparatively few of the pigeons returned to Paris. In order to adapt the weight of the return document to the capacity of the bird, long messages and letters were reduced by photography to within an area not exceeding one or two square inches on paper of the thinnest texture. These slips were generally enclosed in a quill, which was fastened to the central tail feather, and when received they were submitted to the microscope and copied. Most of the balloons were under the management of sailors, whose nautical training, it was supposed, would peculiarly fit them for navigating the air. Several fell into the hands of the enemy, dropping within the hostile lines; and one, the *Washington*, which left Paris on Oct. 12, was subjected, while crossing the Prussian outposts at an elevation of 2,500 to 3,000 feet, to so severe a fire that the travellers were obliged to ascend rapidly several hundred feet. Some were carried to considerable distances beyond the French frontier, and the *Ville d'Orléans* was swept into Norway, and came to anchor 600 m. N. of Christiania. Three have never been heard from since they left Paris. To avoid the enemy's fusillade, it was determined in the latter part of November to despatch the balloons at night; but as no flights were permitted in them by the government, the subsequent journeys were attended by unusual perils, the aeronauts being unable to determine their rate or direction of travelling or their distance from the earth. To this unwise provision was doubtless owing the loss of the balloons above mentioned, and the eccentric courses which others took. Gambetta, the leader of the provisional government, was one of the first to leave the city by this means of conveyance, in order to take the control of affairs at Tours. On the night of Dec. 2 Dr. Janssen departed in the balloon *Volta* for the purpose of observing the total eclipse of the sun on Dec. 22. He noticed that the balloon fell at sunrise and rose again when the sun was several degrees above the horizon, and accounted for this effect by the fact that the envelope upon receiving the first beams of the sun began to radiate heat into space and became rapidly cooler, deriving less heat from the rising sun than it parted with by radiation. This process being finished, it became again susceptible to the sun's rays and reascended. Since the termination of the war it has been announced that the German government have determined to take active steps to effect improvements in military ballooning, and to make it a part of their system.—Notwithstanding nearly a century has elapsed since the inven-

tion of the balloon, little or no improvement has been made upon its original form. It consists now, as in the time of Montgolfier, of a spheroidal bag of gas enclosed within a network, attached by ropes to a ring or hoop, from which is suspended a car for the conveyance of the aeronaut. In place of heated air

The Modern Balloon.

or hydrogen, the latter of which is expensive and requires an elaborate apparatus for its production, it has for many years been customary to use carburetted hydrogen or common coal gas, the mean density of which is about one half that of the air. This improvement in aërostatics was first introduced by Mr. Green, the English aeronaut. The height to which a balloon will rise is determined from the law according to which the density of the atmospheric strata diminishes as the distance from the earth is increased. The buoyant force diminishes with the density, and when it is reduced to a quantity only equal to the weight of the balloon and its appendages, no further ascension can take place. As the pressure of the external air is diminished the expansive force of the confined gas becomes greater; and a balloon quite filled at the surface of the earth would inevitably be torn to shreds at the height of a few miles, unless a portion of the confined gas were allowed to escape. For this purpose the neck of the balloon, into which the gas is introduced, is commonly left open, and the machine is also furnished with a safety valve at the top, which can be opened or shut at pleasure. The valve shown on the next page, invented by M. Giffard, a well known manufacturer of balloons, is considered by M. Tissandier and other high authorities to be perhaps the best thus far made. It consists of a metallic disk four feet in diameter, which is pressed against a wooden hoop by sixteen steel springs; by means of the rope attached to its centre it may be held open, but on this being released it springs back to its place. A good precaution, besides

the opening of the valve, and one generally adopted, is to inflate the balloon only partially at the surface of the earth. Mr. Glaisher is

Balloon Valve Invented by M. Giffard.

of the opinion that in order to reach great altitudes the balloon must have a capacity of at least 90,000 cubic feet, of which not more than one third need be inflated with gas, and must carry upward of 600 pounds of ballast. With such a machine he reached a height of seven miles, at which elevation, as we have seen, he became insensible and his companion nearly so. The question of the extreme altitude to which a balloon can ascend can therefore only be theoretically determined, since the vital powers, however strongly organized, must at 37,000 to 40,000 feet of elevation succumb to the intense cold and the attenuated atmosphere which there prevail. The balloon usually rises in an oblique direction under the combined influence of the vertical ascensional force and the direction of the wind. As soon as it mounts into a stratum of air having the same density as itself, it ceases to ascend unless more ballast be thrown out, and follows the course of the aerial current. As regards the particles of air which surround it, it is quite motionless, and the aeronaut may be swept along with the swiftness of a tornado, with nothing to indicate to him, if enveloped in clouds, that he is not in the quiet of a calm. M. Flammarion states that in an aerial journey of 120 m. he never felt himself in motion, and that from a glass of water filled to the brim, which was placed within the car, not a drop was shaken out, although the balloon was constantly rising and falling hundreds of feet. Not the least remarkable phenomenon which presents itself to the aeronaut is the concave appearance of the earth, which arches beneath him as the dome of the sky does above, so that he may be said to float between two vast concavities. In descending, the aeronaut reduces the buoyancy of the balloon by a skilful management of the rope which controls the safety valve, and when the descent becomes too rapid he lightens the machine by throwing over ballast. This is an operation which should be committed only to a practised hand. So deli-

cately does the balloon respond to any alteration in its weight that, as M. Tissandier relates, the throwing out of a chicken bone once caused him to rise from 20 to 30 yards. In descending through a heavy bank of clouds the weight of the balloon may also be considerably increased by the deposited moisture, and the most rapid discharge of ballast will sometimes scarcely prevent a violent collision with the earth. Under such circumstances the guide rope suspended from the car, first adopted by Green, proves of great advantage by acting as a sort of substitute for ballast, as every inch of it which rests upon the ground relieves the balloon of an equivalent portion of its weight.— Of the innumerable schemes which have been propounded for the guidance and propulsion of balloons, not one has proved available, and the machine is still manageable only for vertical motions. It is within the power of the aeronaut to ascend to the utmost height at which human existence is possible, but when he desires to move in a horizontal direction he is for the most part like a rudderless ship at the mercy of the winds and waves. Starting from a given point, he may traverse the segment of a circle, or describe the most eccentric course, and after hours of aerial navigation be as far as ever from his proposed goal. He can rise or fall at pleasure into a current of air seeming to waft him in the desired direction; but so capricious and infinitely various are the atmospheric streams, and so imperfectly defined are their courses, that he will be most likely to find himself only baffled and confused by them. In spite of the results which acrostatics offered in connection with the siege of Paris, Mr. Glaisher seriously doubts the practical use of the balloon. He sees no probability that any method of steering it will be invented, and even intimates that this is not necessarily the first step in aerial navigation, and may possibly have no share in the solution of the problem. He would employ it simply as an aerial observatory, whence an infinite variety of phenomena affecting the laws which control the universe can be noted with a precision not attainable on the surface of the earth. Messrs. Fonvielle and Tissandier, on the other hand, believe that the guidance of balloons has nothing impossible in it, and lay particular stress upon the use to be made by the aeronaut of the natural currents of air flowing at various heights in the atmosphere. But information with regard to these is at present entirely too vague to justify their confidence. Various plans of aerial ships to be propelled and steered by fans, paddles, sails, or other mechanical contrivances, have been projected in Europe and America, all of which, having been designed in ignorance of or indifference to the most rudimentary atmospheric laws, have proved failures. Under the conviction that the balloon can never solve the problem of aerial navigation, the "Aëronautical Society" was established in England a few

years ago, under the presidency of the duke of Argyll. Absolutely nothing has been accomplished by it yet except to organize a series of experiments on the relation between the pressure and the velocity of air.—See "Travels in the Air by James Glaisher, F. R. S., Camille Flammarion, W. de Fonvielle, and Gaston Tissandier, edited by James Glaisher, F. R. S." (London, 1871).

ÆSCHINES. I. An Athenian orator, rival of Demosthenes, born at Athens in 389 B. C., died at Samos in 314. He was the son of Atrometus and Glaucothea. Demosthenes says Atrometus was a freedman and Glaucothea a prostitute. Æschines, on the contrary, says his father was a true-born Athenian. Demosthenes upbraided him with the fact that his father was a schoolmaster, as though it were a low and sordid occupation. Æschines was afterward clerk to a magistrate, and thus obtained some insight into the laws of his country. He subsequently tried his fortune on the stage, served with distinction in the army, and finally appeared as an orator on the public arena. He was public clerk for two years, and a satellite of the orators Aristophon and Eubulus. In 347 he was sent, along with Demosthenes, as one of the ten ambassadors to negotiate a peace with Philip of Macedonia. From this time forth he favored the Macedonian alliance, and opposed the patriotic party of Athens, headed by Demosthenes. He formed one of the embassy who went to receive Philip's oath to the treaty. Timarchus and Demosthenes accused him on his return of malversation. He evaded the danger by a counter prosecution against Timarchus, on account of his bad moral character, which succeeded. Shortly after the battle of Charonea, in 338, Ctesiphon, an Athenian, proposed that Demosthenes should receive from the state a golden crown. Æschines indicted Ctesiphon for bringing forward an illegal and inappropriate resolution. The cause was not tried until 330, six years after the death of Philip, and when Alexander was in Asia. Ctesiphon was acquitted, and as Æschines had not gained one fifth of the aggregate votes cast, he was liable to pay the penalty inflicted by the Athenian law on him who brought forward a factious resolution. Being unable to pay this penalty, he retired to the island of Rhodes, where he taught elocution for a livelihood, and became the founder of the Rhodian school of oratory. Three speeches of his are extant, showing great narrative and descriptive power, and freer from personal abuse than those of Demosthenes, who reluctantly acknowledged the merits of Æschines. The first is on malversation in his embassy, the second is against Timarchus, and the third against Ctesiphon. II. An Athenian philosopher, a follower of Socrates, and the son of Charinus, a sausage maker. Socrates used to say that the sausage maker's son was the only man who knew how to honor him. Poverty obliged him to go to the court

of the younger Dionysius, the Syracusan tyrant, where Plato, then in the ascendant there, treated him with contempt, but Aristippus gave him a large reward for his dialogues. On his return from Sicily, he taught philosophy for a living at Athens. He wrote orations for the forum for hire. Several dialogues on ethical subjects have been with doubtful justice ascribed to him.

ÆSCHYLUS, the eldest of the great Attic tragedians, the son of Euphion, born at Eleusis in 525 B. C. (4th year of the 63d Olympiad), died in 456. He was of a noble family of the class of the Eupatridæ, and it is probable that he traced his origin to Codrus, the last king of Athens; for among the life archons, who succeeded the kings, was an Æschylus, in whose reign the Olympiads commenced. It is believed that his father was connected with the worship of Ceres; and he was probably himself accustomed from his youth to the spectacles of the Eleusinian mysteries, into which he was afterward initiated. A portion of these he seems to have described in a strange fragment from his drama of the Edoni, the remainder being lost, and he was accused of divulging their secrets in his tragedy of the Eumenides. Pausanias relates of him that Bacchus, of whose worship tragic and dithyrambic odes and spectacles formed a part, appeared to him in a vision—as he himself asserted—when he had fallen asleep in the fields one day, while he should have been watching the vines, and commanded him to write tragedy. At the age of 25 he made his first attempt as a tragic poet; but the next shape in which we find him mentioned is that of a warrior, when, with his two brothers, Cynægirus and Aminias, he received public honors for distinguished valor in the famous field of Marathon. Six years after that battle he gained his first tragic victory, and four years afterward again fought at Salamis, where his brother Aminias received the prize for the greatest courage, being the trierarch who sank the first Phœnician ship, as the poet himself has related in his *Perse*, although modestly refraining from mention of this hero's name. He again fought at Plataea, and eight years after this gained the prize for a trilogy, or series of three dramas presented at a single representation, of which the "Persians," the earliest of his extant works, was one. In the latter part of his life he was defeated by Simonides in an elegiac contest for the prize offered for the best elegy to the honor of those who fell at Marathon; but for many years he was esteemed the greatest of tragic poets, having composed, it is said, 70 dramas, 5 of which were satyric, the rest tragedies of the loftiest tone, and gained 13 tragic prizes before he was at length defeated by Sophocles, in 468. Soon after this, whether in disgust at this loss of his poetic laurels, or at a trial to which he is said to have been subjected on an accusation of impiety for the disclosure of the Eleusinian mysteries, as related above, he retired to Sicily,

where he was hospitably received by Hiero, in whose honor he composed a drama styled the "Women of Etna"; and he died at Gela, in the 69th year of his age. The real circumstances of his accusation and trial are unknown. Clemens Alexandrinus states that he was tried by the court of the Areopagus and acquitted; while Ælian relates that he would have been stoned to death by the Athenians, had not his brother Aminias awakened the sympathies of his would-be executioners by baring his mutilated arm, from which the hand had been hewn by a Persian scimitar as he was struggling to prevent the launch of a galley from the beach at Marathon. It is, moreover, doubtful whether he ever revisited his native country between the period of his expatriation and that of his death, although many of his pieces, among others the celebrated *Oresteian* trilogy, composed of the *Agamemnon*, the *Choephoroi*, and the *Eumenides*, which gained the tragic prize in 458, were performed during this period. The latter fact seems to disprove the whole story of the accusation of impiety as the cause of his taking umbrage toward Athens, as it certainly disposes of its connection with his removal to Sicily. Most doubtful of all is the received account of his death, which was occasioned, says the legend, by an eagle flying overhead with a tortoise in his claws, and dropping the reptile on the bald head of the poet, which he mistook for a stone.—Æschylus was a great improver of the Attic tragedy; in fact, it is he who gave to it first the tragic form, by introducing a second performer, with dialogue, emotion, and action. He also abridged the length of the dithyrambic odes, caused a regular stage to be erected, and was the first to produce his dramas with appropriate scenery and clothe his heroes in befitting costumes. Of his 70 dramas, but 7 have come down to us entire—the *Seven* against Thebes, the *Suppliants*, the *Persians*, the *Prometheus Bound*, the *Agamemnon*, the *Choephoroi*, and the *Eumenides*; with but a few fragments of the others. Æschylus is undoubtedly the grandest, the stateliest, and the most solemn of the Attic tragedians; and his style, though difficult and at times rugged, is magnificently sonorous with its many-syllabled compounds. His creed is that of a blind, overruling, ever-present, inevitable necessity, against which it is vain to contend, from which it is hopeless to escape, yet which it is alike the duty and the glory of the great, good man to resist to the end undaunted; of ancestral guilt continually reproduced and punished by the successive guilt of generation after generation; of hapless kindred criminals, who would not be criminals could they avoid it, but are goaded on to the commission of ever new atrocities by the hereditary curse of the doomed race. Such are the legends of the Theban Labdacidae and the Mycenaean Atridae, predestined murderers, adulterers, and parricides; inextricably involved in the dark net of necessity. It is objected to Æschylus that he

deals with horrors only; that his lyre has but one chord of dark and disastrous terror; that he is all iron, and has no key with which to attune the tenderer strings of human sympathies. But it is doubtful whether there is to be found in the whole range of Greek letters deeper pathos than that of the woe of Prometheus, crucified on his Scythian crags for his love to mortals; than that of the choruses in the *Agamemnon*, descriptive of the disconsolate sorrow of Menelaus deserted by his faithless Helen; and of the sacrifice at the father's bidding of the devoted Iphigenia. Less polished, he is grander than both Sophocles and Euripides.—The tragedies of Æschylus have been rendered into English verse by Dean Potter. A more poetical version is that of the *Prometheus Bound*, by Mrs. Elizabeth Barrett Browning. The great trilogy, the *Agamemnon*, *Choephoroi*, and *Eumenides*, was translated (London, 1865) by Miss A. Swanwick, assisted by Mr. Francis Newman. In 1866 appeared Dean Milman's translation of the *Agamemnon*. The most esteemed editions of Æschylus are by Schütz (Halle, 1808-'21), Dindorf (Leipsic, 1827, and Oxford, 1832), and Scholefield (Cambridge, 1830). Blomfield's edition is excellent as far as it is completed, but it contains only five of the seven tragedies that are still extant.

ÆSCULAPIUS (Gr. Ἄσκληπιός), in Greek mythology, the god of medicine and the patron of physicians. In the Homeric poems he is only spoken of as the "blameless physician," whose sons were serving in the Greek army before Troy. The most common story makes him the son of Apollo. He went about healing diseases and raising the dead to life. Pluto, god of Hades, took alarm at the latter exploit, and complained to Zeus, who struck Æsculapius dead with a flash of lightning. The most renowned seat of Æsculapius's worship in Greece was Epidaurus, in Argolis. He had a splendid temple there, with a statue half as large as that of Zeus Olympius at Athens. The cock was commonly sacrificed to him, but the serpent was his favorite type. At Epidaurus a peculiar breed of holy serpents were kept about the temple, and into them the god was supposed to insinuate himself. When a city was afflicted with a pestilence, it used to send to Epidaurus for one of these Æsculapian snakes, out of the sale of which the Epidaurian priests reaped large profits. The presence of the god in the pest-stricken city, in the form of a yellowish-brown snake, was held to be propitious, and likely to allay the rage of the pest. About 400 B. C. the Romans, under the pressure of calamity, sent a solemn embassy to request the presence of one of these representatives of Æsculapius. On a later occasion of the same nature (293 B. C.) the worship of Æsculapius was introduced into Rome. There were also famous temples erected in his honor at Cos, Cnidos, and Rhodes. In all these temples were tablets commemorating wonderful cures, on which were recorded the name and genealogy

of the patient, his disease, and the mode of recovery. The priests of these temples formed the race of Asclepiadae, or children of Æsculapius. They were the only regular physicians of antiquity. Formerly the priesthood of Æsculapius was hereditary, but in later times the priests took pupils and initiated them into the mysteries of medicine.

ÆSOP (Gr. *Αἰσωπος*), the fabulist, born about the year 620 B. C., was convicted of the crime of sacrilege while ambassador of Cræsus at Delphi, and thrown from a precipice, about 564. His birthplace is not certainly known, though Phrygia is generally mentioned. While young he was brought to Athens and sold as a slave, but finally received his freedom from his master, Iadmon the Samian. So high was his reputation as a writer that Cræsus, king of Lydia, invited him to reside at his court. He visited Athens during the reign of Pisistratus, where he wrote the fable of "Jupiter and the Frogs." His genuine works have perished, the excellent collection going by his name being either imitations or entirely spurious. The current stories concerning him are taken from a life written by Maximus Planudes, a monk of the 14th century, and prefixed to a volume of fables ascribed to his pen. In this work he is described as hideously ugly and misshapen, which statement is doubtless entirely false, as no personal defects of the kind are mentioned by any classical author. It is rendered still more improbable by the circumstance that his statue was executed for the city of Athens by the famous sculptor Lysippus.

ÆSOPUS, Cædus, a famous tragic actor at Rome, died at a great age about 50 B. C. He was the contemporary of Roscius, and with him the instructor of Cicero in oratory. He was accustomed to identify himself so completely with his part, that once while enacting the character of Atreus, and plotting how to avenge himself on Thyestes, he struck dead with his truncheon one of the stage attendants. He realized a large fortune by his acting, which his son squandered in extravagance and luxury.

ÆSTHETICS (Gr. *αισθητικος*, perceptive, from *αισθάνομαι*, I feel, or perceive by the senses), the science of the beautiful, first recognized as an independent branch of philosophy about the middle of the last century. Even the ancient philosophers had speculated upon the beautiful. Pythagoras tried to express its form in numerical proportions; Socrates and Plato united it with the good, and called the highest ideal by the compound name "kalokagathon"; Aristotle strove to give its laws in formulas; and later metaphysicians, down to the recent schools, continued these attempts to define its conditions and effect. But Baumgarten, a disciple of the German philosopher Wolf, and in 1740 professor of philosophy at Frankfort-on-the-Oder, first established its claims to the dignity of a separate science. He held that besides the divisions adopted by Wolf's system, namely, the capacity of knowing (intellect),

the ultimate ideal and aim of which is the true, and the capacity of acting (will), the ultimate aim of which is the good, there exists also in the human mind a capacity of feeling, or perceiving by the senses (sensibility), the ultimate ideal and aim of which is the beautiful. As logic determines the laws of intellect, and ethics those of will or action, so there should be a branch of philosophy, which he called æsthetics, to determine the laws of sensibility. He made the mistake of considering this faculty, by which men perceive the beautiful, a lower capacity founded in the mere exercise of sense (*cognitio sensitiva*); but Kant, who in his *Kritik der Urtheilskraft* accepted the general division given above, corrected this, and showed that the æsthetic perception, for which the senses form only a means, really falls within the province of the high power of judgment. After 1742 Baumgarten lectured regularly on æsthetics, and its place as a philosophical science was almost universally recognized. In this purely abstract psychological consideration of the subject he followed Kant, who held that the beautiful was the harmony between the understanding and the imagination; and, after him several other German philosophers of much less note. Hegel's great work (*Æsthetik*) also treats the subject from this point of view; and Fichte belonged entirely to the ideal school of writers on the æsthetic perception. But the name æsthetics soon began to be received in a more practical acceptation, and to be especially applied to that part of the science of the beautiful which relates to the expression and embodiment of beauty by art. Schiller first turned speculation in this direction; and Schelling, though devoting much study to the abstract, still contributed largely to the useful endeavor to bring the beautiful to the actual knowledge of men, rather than to analyze its psychological effects; and from their time this approach to the identification of the ideal and real has formed the chief and ultimate aim of the study of æsthetics. Two widely different theories as to the realization of the beautiful in art have been adopted by the different schools. One, the method *à priori*, strives by abstract reasoning to determine the laws of the beautiful, with which artists must comply; the other, the method *à posteriori*, seeks for the beautiful in existing works of art, and from the results of such investigation makes practical rules for future guidance. The former has among its adherents most of the German, and the latter nearly all the English and French writers on æsthetics.—Those German authors whose works best deserve study are as follows: A. G. Baumgarten, *Æsthetica* (Frankfort-on-the-Oder, 1750); Georg Friedrich Meier, *Anfangsgründe aller schönen Wissenschaften* (1748); Hegel, *Æsthetik* (Berlin, ed. 1842-'3); Weisse, *System der Æsthetik* (Leipzig, 1830); Schiller, *Æsthetische Briefe*, in Cotta's editions of his works; Zimmermann,

Geschichte der Aesthetik (Vienna, 1858); Vischer, *Aesthetik, oder Wissenschaft des Schönen* (Reutlingen, 1846-'57); Zeising, *Aesthetische Forschungen* (Frankfort, 1855); Köstlin, *Aesthetik* (Tübingen, 1863); Gottfried Semper, *Der Stil in den technischen und tektonischen Künsten, oder praktische Aesthetik* (Frankfort, 1860-'63); J. Dippel, *Handbuch der Aesthetik, &c.* (Regensburg, 1871). Among Englishmen, Dugald Stewart, Hutcheson, Alison, Jeffrey, and Payne Knight have written on æsthetics; Burke wrote "A Philosophical Inquiry into the Origin of our Ideas of the Sublime and Beautiful," but the work has little depth. The opposing theories of these older writers have long ceased to attract attention; and, as in Germany, later works on the subject have followed the method *à posteriori*. Sir William Hamilton, it is true, in his "Lectures on Metaphysics," considers in the abstract the philosophy of the beautiful; but other recent writers, like Ruskin, whose æsthetical works are the most voluminous, treat of beauty in form and color. Two recent American works may be also noticed: "The Science of Æsthetics," by Henry N. Day (New Haven, 1872), and "Lectures on Æsthetics," by Professor John Bascom (New York, 1872). One of the best modern writers on æsthetics is the French critic Hippolyte Adolphe Taine, whose principal works on art form a series of essays on the productions of almost every school. See his *Philosophie de l'art* (Paris, 1865), *Philosophie de l'art en Italie* (1866), *Voyage en Italie* (1866), *L'Idéal dans l'art* (1867), *Philosophie de l'art dans les Pays-Bas* (1868), &c., translated into English by J. Durand (New York, 1866-'70). Among older French writers on æsthetical subjects are Cousin (*Le vrai, le beau et le bon*) and Jouffroy (*Cours d'esthétique*, Paris, 1842).

ÆTHRIOSCOPE (Gr. *αἰθριος*, clear, and *σκοπεῖν*, to observe), an instrument invented by Sir John Leslie for measuring the relative degrees of cold produced by the radiation toward a clear sky.

In a metallic cup standing upon a tall hollow pedestal, a differential thermometer is placed in such a manner that one of its bulbs is in the

focus of the paraboloid formed by the cavity of the cup, and the other bulb is beyond the hollow of the cup. The interior of the cup is highly polished, and is kept covered by a plate of metal, and only opened when an observation is to be made. As the second bulb is out of the cup, it is not affected by the radiation, the action of which is concentrated upon the first bulb. The contraction of the air in this bulb by its sudden exposure to a clear sky causes the liquid in the stem to rise. The figure represents a vertical section of the æthrioscope. A B C D is the parabolic cup, of which the inside is plated with silver and well polished; in its focus one of the bulbs F of the differential thermometer F I T is placed; the other bulb T is outside the cup. Any difference of expansion between the air in the two bulbs is made visible by the motion of a short column of fluid in the tube, and read off on the scale in H. The support E K, with a hinge in I, connects it with the heavy footpiece G, so that it may be inclined in different positions, and directed toward different portions of the sky. Its inclination should never be made such as to expose the thermometric bulb in the focus F to terrestrial objects above the horizontal line H H, as these would either reflect or radiate terrestrial heat, and so entirely or partially annul the cooling of the bulb F by its own radiation. The polished surface of the cup, like all such surfaces, cannot radiate its own heat, but only reflect that of the bulb F; it forms thus a barrier between the earth and the cup, impenetrable to terrestrial heat.—Leslie could not interpret the indications of this instrument satisfactorily. Not only a passing cloud checked the loss of heat, but, he says, "sometimes under a fine blue sky the æthrioscope will indicate a cold of 50 millesimal degrees, while on other days, when the air seems equally bright, the effect is scarcely 30°." It has only recently become known that such differences are due to the presence of aqueous vapors in the air, totally invisible to the eye, but which, being more or less opaque to the feeble rays of radiant heat, screen the bulb and reflecting cup of the æthrioscope against loss of heat by radiation, while a dry atmosphere admits this radiation to pass, and more freely in proportion as the air is more dry. The æthrioscope is therefore at the present day used as a hydrometer to determine the amount of invisible moisture present in the upper inaccessible strata of our atmosphere.

ÆTIUS, a famous Greek painter, supposed to have lived in the first half of the 2d century. He was distinguished for the beauty of his coloring, and esteemed the first painter of his time. Lucian gives a description of a very fine painting by him, representing the nuptials of Alexander and Roxana, which was played at the Olympic games.

ÆTIUS, surnamed the Atheist, from his supposed denial of the God of revelation, an oriental heresiarch, born in Antioch, died in Constantinople, A. D. 367. In early life he was

successively the slave of a vine-dresser's wife, a travelling tinker or a goldsmith, and a quack doctor. He then studied medicine and theology at Antioch, and became prominent as a disputant. His theories (the chief of which were the Anomœan doctrines that the Son is of a nature unlike and inferior to that of the Father, and that the Holy Spirit is but a creature made by the Father and Son before all other creatures) incensed the Arians, and he was thrice compelled to seek safety in flight; but at length he was ordained deacon by Leontius, bishop of Antioch. He now developed, in connection with Eunomius, his pupil and amanuensis, a new schism known as the Aëtian or Eunomian heresy, and made many disciples. He was condemned by the council of Seleucia in 359, and banished by Constantius to Amblada, in Pisidia. After the death of Constantius he was recalled to Constantinople by Julian, and made a bishop. He adopted every means of spreading his heresy, but, having by his intrigues and immorality alienated all his friends, died unpitied by any but Eunomius, who buried him.

AËTIUS, a general of the western empire, born in Mœsia about A. D. 396, murdered in 454. He was brought up, owing to the influence of his high-bred Italian mother, in the imperial body guard of Honorius, and after the death of his father Gaudentius, an illustrious Scythian and master general of cavalry, who lost his life in a mutiny, he was given as a hostage to the king of the Huns. On his return to Rome he was made count on occasion of his marriage with the daughter of Carpileo, and became attached to the household of Joannes. After an ineffectual support of this usurper in 425 with an army of 60,000 Huns, whom Aëtius conducted into Italy under the guidance, it is said, of the then youthful Attila, he turned traitor against the treacherous cause he had espoused, and after the death of Joannes he succeeded in obtaining from Placidia, mother of Valentinian III., the chief command over the army of Gaul, as the condition of his procuring the peaceful retreat of the Huns. In this post he displayed great military skill, delivering Aries from the Visigoths, recovering from Chlodio, king of the Franks, the parts of Gaul bordering on the Rhine, overpowering the Juthungi in Bavaria, bringing to an end the Vindelician war, and in the following spring crushing the confederated forces of the Burgundians, Huns, Heruli, Franks, Sarmatians, Salians, and Geloni, in one terrible encounter. In 432 his rival Boniface, who had been urged to treason and then betrayed by himself, returning from the province of Africa, which his treason had thrown into the hands of the Vandals, and obtaining the dignity of master of the horse, they fought a duel at Ravenna on the challenge of Aëtius, of the wounds received in which Boniface soon afterward died. But Aëtius, fearing for his life, which was threatened by his late rival's adherents, fled into Pan-

nonia, and led a second army of Huns into Italy, threatened the throne of Valentinian, and, although the feeble emperor called in the aid of the Visigoths, forced the empress and her son, without an engagement, to submit to his terms, and returned as before with accumulated honors, to resume command of the army of Gaul. Here he once more displayed genius as a general, routing the Burgundians with exceeding slaughter, and forcing their king to throw himself on his mercy. In the mean time, Roas, king of the Huns, died, and was succeeded by Attila and his brother Bleda, the latter of whom being soon murdered, Attila assumed the sole dominion, and was speedily involved in hostilities with both the Roman empires. For several years his arms were directed chiefly against the eastern empire, but in 451 he set in motion his vast army of a thousand nations, debouched from the defiles of the Hercynian forest, crossed the Rhine on rafts, and fell like a torrent on the rich plains of Gaul. Here for a time all fell before him, till, when he was in the very act of storming the walls of Orleans, while his Huns were mounting the breaches, the spears of Aëtius and Theodoric the Visigoth appeared on the horizon, and, amid cries of "The aid of God" from the beleaguered citizens, the siege was raised, and the Hunnish hordes were forced to retreat. Some days later a tremendous pitched battle was fought on the field of Châlons, in Champagne, in which 162,000, or, according to other accounts, 300,000 men fell on both sides. The Huns were so completely defeated, that Attila prepared a funeral pile and contemplated burning himself alive, with his treasures, his women, and his baggage wagons, had the Romans renewed the battle on the following day. But Theodoric lay dead, and Aëtius suffered the Huns to escape. After this he purposely remained inactive during the remainder of the war, took no measures to oppose the invasion of Italy, and even advised Valentinian to evacuate that country and take refuge in Gaul, which would have left himself master of Rome, where by his great abilities he would speedily have rid himself of the Huns and assumed the imperial purple. Aëtius is believed, according to Marcellinus, to have been implicated in the sudden death of Attila (453); but there is no evidence to support this, excepting that Aëtius always had his emissaries, in the shape of confidential Greek secretaries, about the person of Attila, who had never ceased to intrigue with him. In the end he fell by a crime and a treason as base as his own, stabbed by Valentinian with his own hand, during a friendly interview. The circumstances of this murder are not clearly known, although a coin which has been preserved, bearing the inscription *Aëtius Imperator Caesar*, proves that he had assumed the imperial purple, and actually declared himself emperor, before he was killed. Nominally a Roman, he invariably betrayed Rome to the

barbarians except when it was for his own interest to defend her, and then the ease with which he conquered them showed what he might have done had he been honest. Nominally a Christian, he brought up one of his sons, Carpilio, in a heathen court, as a heathen, and destined him to wear the crown of a heathen nation; while the other, Gaudentius, he proposed to invest, after himself, with the purple of the western empire. Gibbon says that during the decay of the military spirit, the Roman armies were commanded by two generals, Aëtius and Boniface, who may be deservedly called the last of the Romans.

ÆTOLIA, a western division of the mainland of Greece, on the N. shore of the gulf of Corinth or of Lepanto, W. of Doris and Locris, and E. of Acarnania, and divided by the narrow strait between Rhium and Anti-Rhium from Achaia. It is bounded W. by the Achelous, now the Aspropotamo, and N. by Thessaly and Epirus. Its chief city in antiquity was Thermus, in the interior, on the river Evenus, now Fidhari. Ætolia is said to have been originally settled in the ante-heroic times by the Curetes, who were conquered by the hero Ætolus, son of Endymion, with a band of followers from Elis, in the Peloponnesus. During the mythic and heroic ages Ætolia was distinguished as the seat of many of the richest and most poetical of the legends of early Greece. In the days of Thucydides, however, the Ætolians were still a barbarous and uncouth tribe. During the Peloponnesian war they played no considerable part, nor do they appear prominently in Greek history until nearly a century later. On the death of Philip of Macedon and the accession of Alexander (336 B. C.), the Ætolians displayed such hostility to the latter as drew down his signal vengeance. According to Pausanias, Greece owed much to the Ætolians for their energy in beating back the Gallic hordes. With this exception, the Ætolians seem to have fought on any side to which the hope of plunder allured them. With Alexander of Epirus, the son of Pyrrhus, they formed a coalition for the sake of dismembering Acarnania for their own advantage; and again they banded themselves with Cleomenes III. of Sparta, hoping to overthrow the Achaean league. After the death of Antigonus Doson of Macedon (220), they carried their arms into the Peloponnesus in a series of predatory incursions, for which they were severely chastised by Philip V., the successor of Antigonus, who sacked and destroyed their capital, Thermus. In the latter years of the second Punic war the Romans were hard set to avert the consequences of the alliance between Hannibal and Philip V. of Macedon; the Ætolians, with their allies, attached themselves to the Romans, and enabled them, by the employment of a small naval squadron, and a trifling body of forces under the praetor Laevinus, to neutralize all the preparations of Philip, until they had rid them-

selves of their principal opponent on the field of Zama (202). At the battle of Cynoscephalæ (197) their cavalry greatly distinguished itself, charging home ten times against the Macedonians, who were at first victorious, and giving the consul Flamininus time to bring up his reserves and convert a half-lost day into a complete victory. For this they expected to reap their reward in the dismemberment of Philip's dominions; but it was denied to them by the Romans. The Ætolians now attempted an alliance against their late allies with Antiochus the Great of Syria, who had been prompted to hostilities against Rome by Hannibal; but after a single defeat by the Roman consul Glabrio in the pass of Thermopylae (191), the latter retreated into Asia, leaving his Greek confederates to the mercy of the enemy. The polity of the Ætolians from this time, and indeed before, consisted of a federal government similar to the Achaean league, at one time embracing a number of neighboring territories; but being swallowed up with the rest of Greece in the universal empire of Rome (146), Ætolia followed her fortunes, and afterward shared the reverses of the eastern empire. Possessed on the irruption of the barbarians by Slavic hordes, Ætolia was reconquered and partially civilized, together with the Illyrians and Dalmatians, by the Venetians during the middle ages, and subsequently became, like the Morea, the scene of deadly conflict against the victorious Turks. In later times it fell under the power of Ali Pasha of Albania, and it was the scene of some of the most important events of the Greek revolution.—The principal seaport town of modern Ætolia is Missolonghi. The climate is delicious, but along the seacoast and the swampy river shores the autumnal season is marked by fevers. The plains are rich and fertile in maize, wine, silk, and fruits; the mountain scenery is magnificent. (See ACARNANIA.)

AFANASIEFF, Alexander Nikolaievitch, a Russian author, born in Moscow in 1826, died in October, 1871. He studied at the university of Moscow, and was secretary to the council of magistrates in that city. He is the author of *Narodniya Ruskiya skazki* ("Russian Popular Tales," 4 vols., completed in 1863), a series of stories taken down from the mouths of Russian peasants, with critical notes. His other great work, *Poeticheskiya vozrzeniya Slavyan na prirodu* ("Poetic Views of Nature entertained by the ancient Slavs," 3 vols., completed in 1869), is a mine of wealth on the subject of Slavic legends and popular conceptions in respect to the spiritual and material world. He was also a frequent contributor to the Russian press of articles bearing on Slavic history, literature, and archaeology.

AFER, Domitius, a celebrated orator, the teacher of Quintilian, born at Nîmes in the reign of Tiberius, died in the reign of Nero, A. D. 60. His pupil speaks highly of his pleadings, and mentions several of his works, none of which have come down to us.

AFFIDAVIT (Lat., he has sworn or deposed), a statement in writing, signed by the deponent and verified by his oath or affirmation made before a person authorized to take it. The affidavit is the instrument by which the action of courts is invoked in proceedings taken in the first instance *ex parte*, either with reference to existing actions or in special proceedings independent of such causes. Thus it is used in actions for the purpose of procuring attachments or injunctions, or in support of motions of any sort incidental to the suit in its ordinary course; or to obtain a writ of mandamus or of habeas corpus, or a warrant for the arrest of a criminal; or upon an application to oppose or vacate any of these or the like proceedings. As affidavits are in such cases *ex parte*, that is to say, when they are presented by the applicant for the relief, there is no final adjudication upon the matter involved until the other party interested has had an opportunity to be heard. But the sworn allegations of the first party are ordinarily sufficient to set the power of the court in motion in his favor. For the reason, too, that an affidavit is *ex parte* or one-sided, it is the general rule that the testimony of witnesses in causes tried in courts cannot be received in this form. A party to an action has the right to cross-examine witnesses offered against him, and this right would be annulled by admitting affidavits against him.—No particular form of an affidavit is prescribed by our law; but in England very lately the courts have made some very expedient rules on the subject which are intended to cure some of the most frequent abuses and defects of these instruments. They require that the affidavit shall be framed in the first person, and be divided into paragraphs consecutively numbered, and each of them containing as far as possible a distinct portion of the subject. The occupation and residence of the deponent must be inserted. When the paper is sworn to by an illiterate person, the jurat, or certificate of the officer who administers the oath, must state that the affidavit was read over to the party, and that he seemed to understand its contents. The jurat must also certify that the signature or mark of the deponent was made in the officer's presence. The affidavit cannot be read in court if there are any interlineations or erasures in the jurat, or if there are any in the body of the affidavit, unless they are noted with the initials of the officer.—As to the form and nature of the instrument generally: If the affidavit is made with reference to any pending action, it should be headed with the title of that action and the name of the court. It must specify the state and county in which it is made, in order that it may appear on the face of the paper that the officer who took the oath had capacity to do so; for the power of the officer in this respect is confined to certain limits, and an oath administered outside of his jurisdiction is a nullity. Then follows the statement of facts, and this, according to a

practice much followed now in New York, should be a simple narrative in the first person and confined to facts which are within the actual knowledge of the deponent. Facts communicated by third persons are not proper, unless the affidavits of those persons cannot be obtained; and in that case the sources of information should be given, and also the reason why the parties who have actual knowledge do not themselves testify. The statement must be signed by the deponent, or marked if he cannot write, though the omission of the signature or mark will not be fatal if the jurat shows that the affiant actually swore to the statement. The jurat is the clause which is appended by the officer taking the affidavit, in which he certifies the time when and the fact that the deponent made oath to the instrument before him.—The persons who may take affidavits are designated by law. In England they are the judges and certain commissioners and authorized attorneys and solicitors. The authority of these last must be entered in a book kept for public reference. Conveyancers who are not attorneys or solicitors of the courts at Westminster cannot be qualified. In the United States, judges, justices of the peace, commissioners of deeds, notaries public, and other and similar officers have authority by statute to take affidavits. All the states also appoint commissioners residing in other states and territories, and give them the same power as to such instruments to be used in the states which appoint them. The certificates of these officers are ordinarily further verified by the secretaries of state of the appointing states, who keep a record of all qualified commissioners. By recent statutes of New York (1863 and 1869), affidavits to be used there may be taken in foreign countries and in other states by any person who is authorized there to exercise a like power. Judges of the higher courts in other states are also vested by most of the states with the same powers given to their commissioners. Generally, the authority of all foreign officials to administer oaths must be verified by some court or higher officer of the foreign state; or when a judge takes the affidavit, his signature must be authenticated by the clerk and seal of his court. Certain officers of the United States residing abroad, the consuls at London and Paris for example, may also take affidavits, and their consular seals sufficiently authenticate their acts. British ambassadors and consuls have similar powers by the English law. In 1862 a law was passed in New York authorizing colonels of the state regiments and certain other military officers to take affidavits of persons in actual service out of the state.—An affidavit of merits is one made by a defendant which sets forth that he has stated the case to his counsel, and that he is advised by him that he has a good defence to the action upon its merits. This affidavit is required by law, in order that a defendant may not delay a plaintiff's remedy by making

groundless defence to his suit; but the requirement of it does not always accomplish the designed object.

AFFINITY, the imputed relationship which exists in consequence of marriage between the husband or wife and the kindred by blood of the other. Thus, for example, the wife's kindred bear the same relation by affinity to the husband that they bear to her by consanguinity. Affinity also exists between the husband and one who is connected by marriage with the blood relations of the wife. Two men, for instance, who are married to sisters are related by affinity, but there is no such relationship between the blood relations of the husband and those of the wife, and it ceases properly when the husband or wife dies without leaving issue. Affinity is significant in the law because it constitutes a disqualification of judges or jurors, equally with consanguinity. When such a disqualification exists, the judge cannot act even with the consent of both parties; and if he does, the judgment may be vacated. Thus it has been held in New York that there was a disabling affinity between a judge and the defendant in a cause before him, because the defendant's deceased husband was a first cousin of the judge, and the son of defendant by that husband was still living. This living son preserved the affinity, which otherwise would have ceased on the husband's death. Affinity is also significant in the laws of marriage. The ecclesiastical law made certain marriages unlawful though they were contracted between persons whose relationship to each other was very remote. Though the statute of 32 Henry VIII., which has virtually furnished the rules of the English law on the subject ever since, forbade the ecclesiastical court to impeach the validity of any marriage between parties who were without the Levitical degrees, yet it was always held under it in England that affinity was an impediment to the same extent as consanguinity; and out of this interpretation of the statute came that rule of the law which has been so much discussed and assailed in England, that a man may not marry his deceased wife's sister. The reason given was that the marriage made the wife's sister the husband's sister; and although in the other branches of the law, with respect to judicial officers for example, the death of either party destroys the affinity and the disqualification, yet the same result has not been conceded in matrimonial cases.

AFFINITY, Chemical, the name given to the force which combines together chemical elements so as to form compounds. Of its real nature or essence we are entirely ignorant, as we are of the essential nature of other material forces. The term chemical attraction has also been applied to this force, on the hypothesis that it draws together chemical atoms. In many cases there can be no doubt that the chemical particles come nearer together when they combine: thus if two volumes of hydro-

gen and one volume of oxygen be caused to unite, we do not get three volumes of steam, but only two; that is, the particles have approached so much closer in combining as to occupy but two thirds of their former space. In other cases, however, compounds are found to occupy exactly the same space that their elements did before combination, and sometimes they fill even a greater space. Hence the term chemical attraction has been thought objectionable. Chemical affinity is that link or tie which binds together unlike kinds of matter, in such an intimate manner that the properties of the elements are lost, and a compound with new properties is produced. It is in this that it differs from cohesion, which only unites or aggregates similar particles without altering properties. The particles in a piece of iron or sulphur are held in union by cohesion; but when sulphur and iron combine chemically, both elements disappear, lose their properties and identity, and a new compound is formed—the sulphuret of iron. Newness of properties in the compounds formed is the distinguishing peculiarity of chemical affinity. It obliterates the characteristics of the elements, and generates new properties in the product. Cohesion is usually said to act between homogeneous particles, as in the cases just cited of sulphur and iron; but it may also act between dissimilar substances, as where silver is inlaid with steel, or copper metal united to tin, or iron coated with zinc, or wood joined to glue, or paper to paste, or pitch to the fingers. These, however, are mechanical combinations; there is no destruction of the properties of the combined substances, and those of the combination are not new, but are the same as the properties of the constituent substances, each of which retains its individuality. The force of gravitation is brought into play between masses of matter at all distances; chemical affinity acts only when the elements are in contact or at insensible distances. For this reason affinity is most energetic when one or both of the elements are in a state of solution, the approach of the atoms being then most perfect. It was once thought that chemical affinity could not take effect without the intervention of solution; and although the statement is generally true, yet there are some substances whose affinities are so intense that they will unite even in the solid state when made to touch each other. The action of affinity is heightened, modified, and suspended by various other causes. Among these heat is most potent, and most easily available in the laboratory and chemical manufactory. Thus carbonic acid and lime unite strongly at common temperatures, forming marble or limestone, but at a red heat their affinity is annihilated and they separate. On the other hand, potash and sand will not actively combine at ordinary temperatures, while at a red or white heat, at which they are melted, combination takes place and glass is formed. Light also influences affinity, promoting combination and

decomposition. If chlorine and hydrogen gases be mixed in the dark they will not unite, but exposed to light they combine at once; while in every green vegetable leaf carbonic acid is decomposed every day under the influence of solar light. The recent investigations in photography have greatly multiplied the number of substances over which light is known to exert a chemical influence. Electricity also has a governing action over affinity. An electric spark, shot through a mixture of oxygen and hydrogen gases, causes them to combine instantaneously and explosively, producing water; while a steady electric stream sent through the water annuls the affinity of its elements and sets them free again. Other causes also, known and unknown, affect in various ways and degrees the play of affinity; indeed, a full statement of them would involve almost the whole science of chemistry.—The changes in the properties of substances produced by affinity are numberless and surprising. When solid charcoal and sulphur combine, the compound formed is colorless as water, and highly volatile. If yellow sulphur and bluish white quicksilver be heated together, they form the bright red vermilion. Waxy phosphorus and colorless invisible oxygen unite to form a white body resembling snow. Nitrogen and oxygen are tasteless, separate or mixed; yet one of their compounds, laughing gas, is sweet, and another, nitric acid, intensely sour; they are both transparent and invisible, yet they form a cherry-red compound gas. Charcoal and hydrogen are odorless; nevertheless, many of our choicest perfumes, such as oils of roses and bergamot, as well as the less agreeable spirits of turpentine and illuminating gas, contain only these elements. The mild and scentless nitrogen and hydrogen give rise to one of the most odorous and pungent compounds, ammonia; while suffocating and poisonous chlorine, united to a bright metal, sodium, yields common salt. Charcoal, hydrogen, and nitrogen, which singly or mixed are not injurious to life, yet combine to form the terrible poison prussic acid; while charcoal, hydrogen, and oxygen, variously united, produce sweet sugar, poisonous oxalic acid, and intoxicating alcohol.—The strength of affinity among different elements is various. Thus the chemical energies of sulphuric acid are superior to those of carbonic acid; if the former be united to carbonate of lime, it takes the lime away from the carbonic acid—that is, produces decomposition and a new compound. It has been attempted to establish a scale of affinities among various chemical substances to form the basis of an order of decomposition; but affinity is disturbed and overcome by so many circumstances that such tables are of but little value. For the laws of affinity or chemical combination, see **ATOMIC THEORY**.

AFFIRMATION, a mode of solemn verification permitted by the law, in the place of an oath, to persons who are unwilling from conscien-

tious motives to be sworn. This departure from the usual rule of exacting an oath was first introduced into the English law in favor of Quakers; but by the present law there, and ever since 17 and 18 Victoria, ch. 125 (1854), any person called as a witness or desiring to make an affidavit or deposition, who will solemnly declare that the taking of an oath is, according to his religious belief, unlawful, may affirm or declare to the truth of his statement; and the statute requires that the officer taking the affirmation shall recite in his certificate that the affirmant declared that an oath was unlawful according to his religious belief. By the statute of 24 and 25 Victoria, ch. 66 (1861), all persons refusing to be sworn in criminal proceedings may make their solemn affirmation instead. In the United States an affirmation, even without the suggestion of any reason for preferring it, is probably everywhere received in place of an oath. The legal effect of both is the same, and perjury is committed by affirming as well as by swearing falsely, wilfully, and corruptly.

AFFRE, Denis Auguste, archbishop of Paris, born at St. Rome-de-Tarn, Sept. 27, 1793, died in Paris, June 27, 1848. He was educated in the seminary of St. Sulpice, and was made teacher of philosophy in that of Nantes before he had attained the age required for the priesthood. After his ordination he was attached successively to the seminary of St. Sulpice and to the founding hospital, and subsequently as grand vicar assisted the bishops of Luçon and Amiens. In 1834 he was attached to the diocese of Paris as canon and honorary vicar general. In 1839 he was appointed coadjutor to the bishop of Strasburg, but never took possession of this office; for the archbishop's see of Paris having become vacant, he was appointed to it, and consecrated Aug. 6, 1840. In this office he distinguished himself by zeal for ecclesiastical education, and for the alleviation of poverty and misfortune. While the insurrection of June, 1848, was raging in the streets of Paris, he determined to make a personal attempt to stop bloodshed. On the 25th he called upon Gen. Cavaignac, and, although warned by him of the great danger of his undertaking, repaired to the faubourg St. Antoine, the stronghold of the insurgents. On his appearance between the two hostile parties at the place de la Bastille, the firing was suspended, and he calmly and steadily proceeded toward the barricades without any protection except the gold cross on his breast and a green branch carried before him, in token of peace, by a young attendant. He was admitted behind the barricades, and had just begun to address the insurgents, when the report of a musket was immediately followed by a renewal of hostilities, and in the confusion the archbishop fell, shot by some unknown hand, and was transported to the hospital of the *Quinze-Vingts*. He expired two days later, a martyr of charity, as was proclaimed by the national

assembly. He was the author of several religious and educational works.

AFGHANISTAN, an extensive country of Asia, between lat. $28^{\circ} 30'$ and 36° N., and lon. 60° and $71^{\circ} 30'$ E., bounded N. by Turkistan, E. by the Punjaub and Sinde, S. by Beloochistan, and W. by the Persian highlands of Khorasan. Area estimated at upward of 215,000 sq. m.; pop. upward of 5,000,000, and estimated even as high as 9,000,000. The surface of Afghanistan is very irregular—lofty table lands, vast mountains, deep valleys, and ravines. Like all mountainous tropical countries, it presents every variety of climate. In the Hindoo Koosh the snow lies all the year on the lofty summits, while in the valleys the thermometer ranges up to 130° . The heat is greater in the eastern than in the western parts, but the climate is generally cooler than that of India; and although the alternations of temperature between summer and winter, or day and night, are very great, the country is generally healthy. The soil, where not too rocky, is very fertile. Date palms flourish in the oases of the sandy wastes; the sugar cane and cotton in the hot regions; and European fruits and vegetables on the hillside terraces up to a level of 6,000 or 7,000 feet. The mulberry tree flourishes in the cool valleys. The mountains are clothed with noble forests, which are frequented by bears, wolves, and foxes, while the lion, the leopard, and the tiger are found in districts congenial to their habits. There is a fine variety of sheep of the Persian or large-tailed breed. The horses are of good size and blood. The camel and ass are used as beasts of burden. The country is rich in lead, plumbago, saltpetre, sulphur, salt, and alum. The iron is believed to be equal to any in the world, while the copper ore yields in some localities nearly 80 per cent. of the metal. Besides the Hindoo Koosh on the northeast, there is a chain called the Solyman mountains on the east and southeast; and between north-western Afghanistan and Balkh there is a mountain labyrinth known as the Paropamisian range, which has as yet been little explored. Several minor ranges traverse the interior. The rivers are few in number; the Helmund and the Cabool are the most important. These take their rise in the Hindoo Koosh, the Cabool flowing east and falling into the Indus near Attock, the Helmund flowing southwest through the centre of the country and falling into the lake of Hamoon. The Helmund overflows its banks annually like the Nile, bringing fertility to the soil, which, beyond the limit of the inundation, is sandy desert. The four principal cities, Cabool, the capital, Ghuzni, Candahar, and Herat, are important stations on the highway of commerce from India to central and western Asia. Cabool and Jelalabad protect the passage to India on the north, Candahar on the south, and Herat, in the extreme west, guards the Persian frontier.—The geographical position of Afghanistan, and

the peculiar character of the people, invest the country with a strategical and political importance that can scarcely be overestimated in the affairs of central Asia. The government is a monarchy, but the king's authority over his high-spirited and turbulent subjects is personal and very uncertain. The kingdom is divided into provinces, each superintended by a royal officer who collects the taxes. The Afghans are a brave, hardy, and independent race; they follow pastoral or agricultural occupations only, eschewing trade and commerce. They are divided into clans, over which the various chiefs exercise a sort of feudal supremacy. The two principal tribes are the Durrans and Ghiljies or Ghilzais, who are frequently at feud with each other. The Durrans are the more powerful, and the military contingents are chiefly furnished by them. Justice in the towns is administered by cadis, but the Afghans rarely resort to law. Avenging of blood is a

family duty; and the rights of hospitality are sacred. In religion they are, with the exception of some not purely national portions of the population, Sunnite Mohammedans, and are consequently opposed to the Persians, who are Shiahs; but they are not bigoted, and alliances between Shiahs and Sunnis are by no means uncommon; and they are tolerant toward Christians and Hindoos.—Afghanistan was subjected for centuries alternately to Mongol and Persian dominion. Previous to the advent of the British on the shores of India, the foreign invasions which swept the plains of Hindostan always proceeded from Afghanistan. Sultan Mahmoud the Great of Ghuzni, Genghis Khan, Tamerlane, and Nadir Shah all took this road. After the death of Nadir in 1747, Ahmed Khan, who had served under him, liberated his country from Persia and made himself king. Under him Afghanistan reached its highest point of greatness and prosperity in modern times. He belonged to the Durrans, and his first act

was to seize upon the booty which his late chief had gathered in India. His kingdom extended from Khorasan to Delhi, and he even measured swords with the Mahratta powers. He died in 1773, and left his crown to his son Timour, who was unequal to the weighty charge. He abandoned the city of Candahar, and removed the seat of government back to Cabool. During his reign the internal dissensions of the tribes, which had been repressed by Ahmed, were revived. In 1793 Timour died, and Zemaun succeeded him. This prince conceived the idea of consolidating the Mohammedan power of India, and this plan was thought so important by the English that Sir John Malcolm was sent to the frontier to keep the Afghans in check in case of their making any movement, and at the same time negotiations were opened with Persia, by whose assistance the Afghans might be placed between two fires. Zemaun's plans were, however, frustrated by a contest between him and his brothers, which ended in Mahmoud's accession to the throne. The latter was compelled to abdicate in 1823, and died in 1829, the last of the Durrani dynasty. Afghanistan was now ruled by three brothers, the eldest of whom, Dost Mohammed, was in possession of Cabool, the most important of the three divisions of the country. He was soon involved in war with Lahore on the east, and on the west with the Persian invaders of Herat, who were believed to be abetted by Russia. In 1838 England declared war against Afghanistan, upon the ground that Dost Mohammed had attacked her ally Runjeet Singh, who had established an independent kingdom in the Punjab, and that Shujah, whom the English regarded as the lawful heir to the throne of Afghanistan, had placed himself under British protection. In December, 1838, the Anglo-Indian army, under Sir John Keane, marched toward Sindh, which country was coerced into submission and the payment of a contribution for the benefit of the Sikhs and Shujah. On Feb. 20, 1839, the British army passed the Indus. It was about 12,000 strong, with 40,000 camp followers, besides the new levies of Shujah, and suffered severely on the march. They penetrated through the Bolan pass, and on April 25 entered Candahar, which the brothers of Dost Mohammed had abandoned. After a rest of two months, Ghuzni, the impregnable stronghold of Afghanistan, was taken, July 22, by blowing open the only gate which had not been walled up. After this disaster the army which Dost Mohammed had collected at once disbanded, and Cabool opened its gates Aug. 6. Shah Shujah was installed in due form, but the real direction of government remained in the hands of the British envoy, Sir William McNaghten, who also paid all Shujah's expenses out of the Indian treasury, as well as those of the principal chiefs. Dost Mohammed surrendered in October, 1840, and was sent to India. The conquest of Afghanistan seemed accomplished, and a considerable portion of the

troops were sent back. But during the whole of 1840 and 1841 insurrection followed insurrection in every part of the country. The Anglo-Indian troops had to be constantly on the move. The occupation of Afghanistan cost the Indian treasury £1,250,000 per annum. McNaghten was informed of the impossibility of going on at this rate of expenditure. He attempted retrenchment, but the only possible way to enforce it was to cut down the allowances of the chiefs. The very day he attempted this, the chiefs formed a conspiracy for the extermination of the British. The English in Cabool were commanded by Gen. Elphinstone, who had been sent as English envoy in 1835 to counteract the alleged anti-English Perso-Russian intrigues. He was a gouty, irresolute, helpless old man, whose orders constantly contradicted each other. The defences and commissariat were neglected, and everything was in confusion. On Nov. 2, 1841, the insurrection broke out in Cabool. The house of the British resident, Sir Alexander Burnes, was attacked, and he himself murdered. On Nov. 3 the forts near the camp were occupied by the insurgents. On the 9th the commissariat fort, garrisoned by only 80 men, was taken, and the British were thus reduced to starvation. In the middle of November negotiations began, during which McNaghten was murdered in a conference with Afghan chiefs. On Jan. 1, 1842, a capitulation was concluded, the British agreeing to evacuate the country, paying a large amount of money, and surrendering nearly all their artillery and ammunition. The chiefs, on the other hand, promised a safe conduct, provisions, and baggage cattle. On Jan. 5 the British marched out, 4,500 combatants and 12,000 camp-followers. The march, through cold and snow, and with scanty food, soon became completely disorganized, while they were harassed by infuriated Afghan marksmen, armed with long-range matchlocks, occupying every height. The chiefs who signed the capitulation neither could nor would restrain the mountain tribes. The Kurd-Cabool pass became the grave of nearly all the army, and the remnant, less than 200 Europeans, fell at the entrance of the Jugduluk pass. Only one Englishman, Dr. Brydon, reached Jelalabad to tell the tale. Many officers, however, had been seized by the Afghans, and kept in captivity. Jelalabad was held by Sale's brigade. He was summoned to surrender, but refused, and made a most gallant defence; so did Nott at Candahar. Ghuzni had fallen; there was not a man in the place that understood anything about artillery, and the sepoys of the garrison had succumbed to the climate. In the mean time, the British authorities on the frontier, at the first news of the disaster of Cabool, had concentrated at Peshawar the troops destined for the relief of the regiments in Afghanistan, which were long detained by lack of transportation. Gen. Pollock received the command, and at the end of March, 1842, forced the Khyber pass, and ad-

vanced to the relief of Sale at Jelalabad; but Sale had a few days before completely defeated the investing Afghan army. It was not till July that Lord Ellenborough, now governor general of India, authorized an advance on Cabool, both from Candahar and Jelalabad; and on Sept. 15 Gen. Pollock, after several battles, encamped under the walls of Cabool. On the 17th he was joined by Nott, who had also fought several battles, and had taken and destroyed Ghuzni. Shah Shujah had long before been murdered by some of the chiefs, and since then no regular government had existed in Afghanistan; nominally, Futteh Jung, his son, was king. Pollock despatched a body of cavalry after the Cabool prisoners, but these had succeeded in bribing their guard, and met him on the road. As a mark of vengeance, the bazaar of Cabool was destroyed, on which occasion the soldiers plundered part of the town and massacred many inhabitants. Oct. 12, the British left Cabool and marched by Jelalabad and Peshawar to India. Futteh Jung, despairing of his position, followed them. Dost Mohammed was now dismissed from captivity, and returned to his kingdom. Thus ended the attempt of the British to set up a prince of their own making in Afghanistan. Dost Mohammed on his return to Cabool was received with ovations as the liberator of Afghanistan both from English and Perso-Russian hostility. As early as 1846 he availed himself of the experience he had gained during his captivity in British India to revive hostilities. Entering into an alliance with his former enemies the Sikhs, he set on foot disturbances in the Punjaub, which were not quelled without much hard fighting. After the battle of Guzerat, however (Feb. 21, 1849), the Sikhs, defeated by the English, were forsaken by the Afghans, and Dost Mohammed with 16,000 of his warriors fled over the Indus. He was not disturbed by the English government, and after having conquered Balkh (1850) and thus consolidated his forces in the north, he even succeeded in 1854 in subduing Candahar, and gaining the supremacy in the southern part of the country. He now concluded an offensive and defensive alliance with England, March 30, 1855; and goaded on by that power, as well as encouraged in his ambition by the death of Yar Mohammed, the ruler of Herat, he became involved in war with Persia (1856), which ended in the evacuation of Herat (July, 1857) by the Persians, and the appointment of Ahmed as sultan of that country. In January, 1857, Dost Mohammed concluded a new treaty with England. In 1860 the sultan of Herat quarrelled with Dost Mohammed's son; but on this occasion, as in the following year, in the complications with the emir of Bokhara, Dost overcame all difficulties by the exercise of his wonted tact and moderation. A new Persian war broke out in 1862; but, supported by his British allies, Dost Mohammed defeated the sultan of Herat and took possession of that city after a protracted struggle, May 26, 1863. Ahmed,

the sultan of Herat, and the tool of Persia and Russia, died shortly before the capture of his capital, and Dost himself survived his victory only a few days, his death occurring May 29, 1863. He bequeathed the throne to his son Shere Ali, who was soon embroiled in a bitter contest for the succession with his brothers and nephews, and Afghanistan was plunged again into anarchy. Helpless against the many pretenders to the throne, Shere Ali appealed to the English, but he was regarded by them as an unsafe ally, and Atzul Khan, Shere's half brother, was recognized by Sir John Lawrence, the governor of British India, as the lawful sovereign. Yacub Khan, Shere's son, had succeeded in retaining power at Herat, and sent assistance to his father, who, however, was disappointed in his hope of making the Persians his allies against his antagonists. In October, 1867, however, he succeeded in gathering an army of 17,000 men, chiefly through the monetary assistance accorded to him by the widow of Feis Mohammed of Balkh. On April 1, 1868, he took possession of Candahar, and in January, 1869, he achieved a decided victory at Ghuzni over his half brother Azim and his nephew Abd-ul-Rahman. In July, 1869, the pretenders rose anew on the boundaries of Turkistan; but Azim Khan, the most mischievous of them, died in October, 1869, and the Anglo-Indian government, afraid of Russia, which was all the time accused of a design to use Persian supremacy over Herat for her own designs on India, now came over to the side of Shere Ali. Earl Mayo, the new governor general of India, entered into a formal alliance with him, recognizing him as the legitimate sovereign of Afghanistan. At the instigation of England, the upper Oxus was at the same time fixed upon as the boundary line between Afghanistan and Bokhara (a country virtually ruled by Russian influence), and a treaty to that effect was concluded and signed in January, 1871. By bringing the difficulties between these countries to a close, Great Britain hoped to arrest the progress of Russia. Shere Ali, however, was still distrusted by his kinsmen, the pretenders to his throne. On Sept. 21, 1870, his own son Yacub rose in revolt against his father, because the latter, owing to a palace intrigue, resolved to appoint his second son Abdullah Jaw successor to the throne, in the place of Yacub. In March, 1871, the fortress of Gurian fell into the hands of Yacub, and in May he even took possession of Herat. A protracted war between father and son was now expected, but through British diplomacy a reconciliation took place in June, in consequence of which Yacub was appointed governor of Herat.—*Afghan Language and Literature.* Afghan is a Persian word. The term *Vilayet* is applied by the people themselves to their country, and signifies the original land of ancestors. They also designate it as Cabulistan, and by other appellations. The inhabitants call themselves Pushtaneh or Pukhi-

taneh, according to the two main dialects of their language, the Pukhtu and Pushtu, which are spoken in different parts of the country. The Afghani, notwithstanding its peculiar sounds, retains the essential characteristics of the Iranic group of the Indo-European languages. Mixed with various oriental tongues and written in Persian characters, it reveals the defective cultivation of the people. There is a tradition that Mohammed described the Pukhtu as the language of hell. Previous to the 15th century there does not seem to have existed any literature at all; but since that period there have been several poets, who took the high-flown Persian lyrical writers as their models. Abderrahman of Peshawar was one of the earliest poets. In the 17th century Mirza Khan Ansari and Khushhal Shah Abdali distinguished themselves as Afghani poets; and Ahmed, the founder of the Durrani dynasty, was remarkable for his literary efforts. Writings on historical and religious subjects are extant among the Afghans, but none earlier than within the last four centuries. Raverty published a grammar of the Pukhtu language (London, 1860-'68), and a selection from the poetry of the Afghans (1862). Among valuable works on Afghanistan are Elphinstone's "Account of the Kingdom of Caubul" (London, 1815); Caye, "History of the War in Afghanistan" (1851); Belly, "Journal of his Political Mission to Afghanistan" (1862); and the travels of Connolly, Burnes, Ferrier, and Bellew.

AFIUM KARA-HISSAR (Black Castle of Opium, so called from its extensive trade in opium, which grows in its vicinity), or simply **Karahissar**, a city in the Turkish eyalet of Khudavendikiar, in Asia Minor, capital of a sanjak or district, 50 m. S. S. E. of Kutaich; pop. about 50,000. It is neatly built upon a mountain side, protected by a fortress, which is perched upon a high rock above it. Manufactories of carpets, felts, arms, stirrups, and saddlery are carried on by the inhabitants.

AFRAGOLA, a town of Italy, 5 m. N. E. of Naples, on the railroad to Rome; pop. in 1861, 16,129. It has manufactures of straw hats, and a great annual fair commencing on the second Sunday of May.

AFRANIUS, Lucius, a Roman orator and writer of comedies, who flourished about 100 B. C. His genius and fluent style are praised by Cicero and Quintilian. In his plays he depicted Roman life, and chiefly its lower features, with admirable accuracy, and was therefore regarded as a worthy imitator of Menander. Only some fragments of his works remain.

AFRICA, one of the great continental divisions of the globe, situated in the eastern hemisphere, S. of Europe, from which it is separated by the Mediterranean sea, and S. W. of Asia, with which it was formerly connected by the isthmus of Suez. Since the opening of the canal between the Mediterranean and the Red sea, Africa may be described as an insular continent. It lies between lat. 37° 20' N. and 34°

50' S., and lon. 17° 30' W. and 51° 30' E., being thus almost wholly within the tropics. Its figure resembles that of an irregular triangle. Its greatest length, measured from Cape Agulhas, E. of the Cape of Good Hope, to Cape Bianco, near Bizerta in Tunis, is 4,330 geographical miles; and its greatest width, from Cape Verd on the Atlantic to Cape Guardafui, on the Indian ocean, is 4,000 geographical miles. The entire area of the continent, exclusive of Madagascar and the other African islands, is estimated at 11,360,000 statute square miles. The derivation of the name, which was originally applied only to the country around Carthage, is uncertain. Within the last 25 years our knowledge of African geography has been so largely increased that the leading physical features of the country are now pretty well known.—Southern Africa is a vast table land, not of great elevation, which on its N. edge slopes down to the rich equatorial plain of Soodan, and thence to the lowland region which constitutes the greater part of northern Africa. The mountain ridges of Senegambia on the west, and the lofty plateau of Abyssinia on the east, are outlying offshoots of the southern table land, stretching forth from it like rocky promontories into a sea of level country. The Atlas range in the northwest is the only other elevated region of importance.—The coast line of Africa is remarkable for its continuity, as well as for its lack of good harbors. It is about 16,000 m. in length, so that for every 710 sq. m. of continental area, according to the estimate above given, there is only one linear mile of coast, a smaller proportion of seashore to surface than in America, Asia, or Europe. The surrounding seas comprise the Mediterranean on the north, the Red sea and Indian ocean on the east, the Southern ocean on the south, and the Atlantic on the west. The island of Madagascar is separated from the S. E. portion of the mainland by the Mozambique channel, 250 m. wide. Just above the equator the breadth of the continent is considerably narrowed by the westward trend of the Atlantic coast through about 15 degrees of longitude, from Cape Palmas to the head of the bight of Biafra, where it resumes its southerly course. The seaboard of this region is washed by the waters of the gulf of Guinea. The most prominent points on the Mediterranean coast are Cape Bon, in Tunis, opposite Sicily, and Cape Spartel, the extremity of a spur from the Atlas mountains forming the African side of the straits of Gibraltar. At the gulf of Sidra, the Syrta Major of the ancients, in Tripoli, the sands of the Sahara reach the shore; and E. of this locality to the delta of the Nile the coast country is flat and unproductive. In Algeria the Atlas foot hills approach the sea, and the contiguous district is well adapted for cultivation. The Sahara desert again borders the shore on the Atlantic coast of northern Africa; and further S. lie the luxuriant but unhealthy lowland delta districts of Senegambia, whence

projects Cape Verd, so named from its rich green covering of gigantic baobab trees. Approaching the equator, these are succeeded by a country still more fatal to man, in the mangrove swamps and reedy shore growths of the Guinea coast. On the Red sea, a range of mountains originating in Abyssinia skirts the W. shore and descends on the north to the lower hills of Egypt, which are geologically connected with the Sinaitic peninsula. The maritime edge of the great South African plateau is bounded for the most part by mountain chains of various altitude, with shelving plains on their seaward slope. Between the E. and W. coasts which border the table land there is a marked difference. Along the Atlantic a series of terraces rises into the interior, intersected in some localities by low, level plains and fever-breeding swamps, and in others by grassy tracts and extensive forests. The highest of these terraces does not exceed 2,000 feet above the sea. From Cape Negro, in Benguela, to the mouth of the Orange river, the coast is a low desert backed by a sandstone ridge, beyond which extends the lofty but no less arid inland region. Along this 900 m. of seaboard there is not a single drop of fresh water, and not a spot of fertility except at Walvisch bay. The coast of Cape Colony is bold and rocky; in Natal the surface rises gradually from the sea to the Drakenberg range, and thence northward to the Zambesi; the shore consists of highlands which in some localities attain the elevation of lofty mountains. Well watered and fertile plains occur opposite Zanzibar, but further N. the country becomes more sterile, and a desert occupies that portion of the continent comprised between lat. 4° N. and Cape Guardafui, its E. extremity. The strait of Bab-el-Mandeb, 20 m. broad, separates Africa from Asia, at the entrance to the Red sea. On the African side the coast is rugged, and rises abruptly from the sea, though only to the height of 380 feet.—Considered with reference to continental location, the mountains of Africa may be classed in five systems, as follows: 1, the mountains of the Mediterranean basin, comprising the three ranges of the Atlas; 2, the mountains of the W. coast; 3, the parallel chains of the Cape region; 4, the mountains of the E. coast; and 5, the Abyssinian group. Isolated from the other parts of the continent by the Great Desert, the Atlas mountains extend across the N. W. portion, from the Mediterranean shores of Tunis to Agadir on the Atlantic coast of Morocco. The Lesser Atlas is the lowest range of this system and nearest the Mediterranean; a little further inland the broad table land known as the Middle Atlas rises still higher; and above this towers the jagged ridge of the Greater Atlas, in many points attaining an elevation of 12,500 ft. It has commonly been represented that these loftier peaks were above the line of perpetual snow; but according to Dr. J. D. Hooker, the English botanist, who succeeded in ascending to the crest of the range

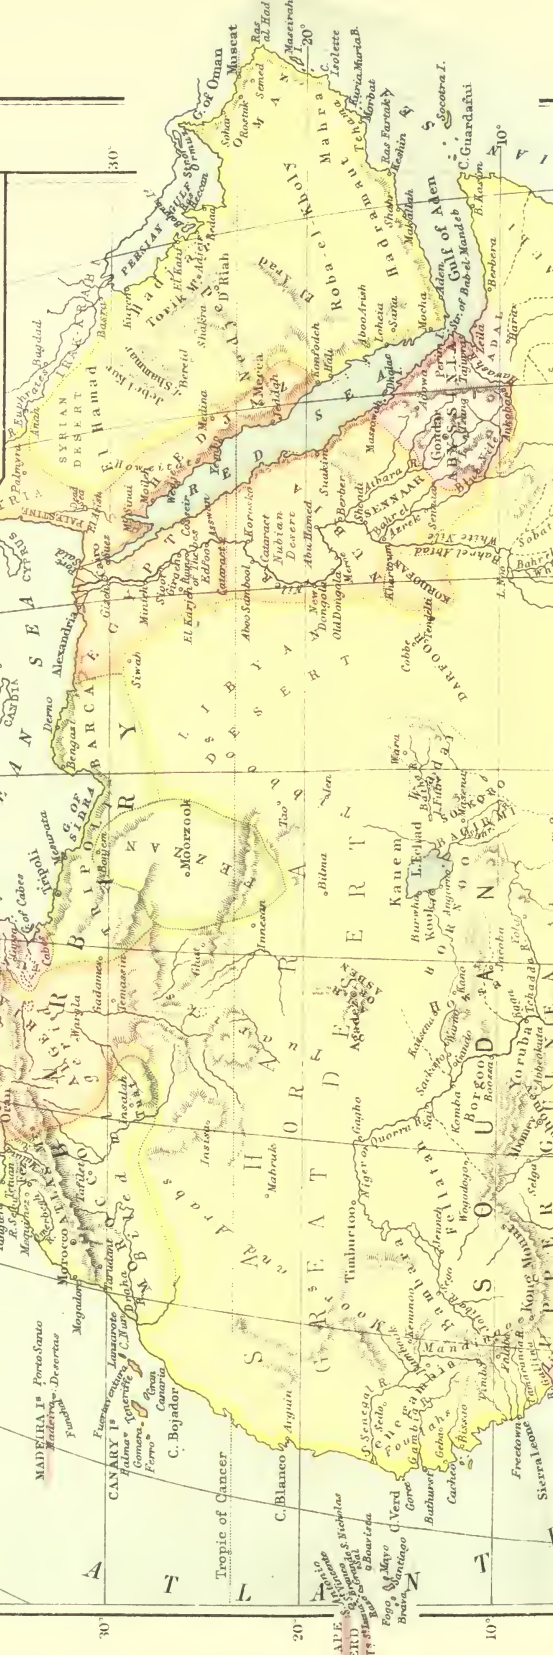

near the city of Morocco in 1871, all the snow that falls on fairly exposed surfaces melts in the same year. Several spurs are thrown out from the main chain toward the Sahara, and one trends northward to the straits of Gibraltar. Little is known about the mountains of western Africa, except those in close proximity to the coast. Senegambia includes an elevated region which forms the watershed whence flow the Niger and the Senegal; while in Guinea, N. of the gulf, are the Kong mountains, nowhere exceeding 3,500 ft. in height. The Cameroons rise from the shores of the bight of Biafra, and extend eastward to an unknown distance, with many lofty summits, some of which are estimated at 13,000 ft., though others do not exceed 4,000 ft. We possess but little information as to the mountains which rise back of the terraced W. coast S. of the gulf of Guinea, but there are believed to be extensive ranges of very considerable height. The mountain system of the Cape country is peculiar. The continent is here 700 m. in width, and partly across it stretch three crescent-shaped ranges parallel to the S. coast, and increasing in elevation with their distance from it. The innermost of these ranges borders upon the great interior table land, and between them are narrow tier-like flats, called karroos, forming three gigantic steps ascending from the ocean respectively 2,000, 4,000 and 6,000 ft. above its level. The karroos are connected by defiles known as kloofs, there being no other means of communication between them. The names applied to the different sections of the intervening ranges are numerous. In the southernmost is the Zwellendam group, of which the most prominent height is Table mountain, 3,582 ft. high; to the middle range belong the Zwartberge, with an average elevation of 4,000 ft.; and on the N. the Roggeveld, Nieuwveld, Sneeuwveld, and others make up the third barrier on the southern edge of the great S. African plateau. The Compass Berg, in the Sneeuwveld, is 10,000 ft. high. The mountains of the E. coast begin with the Quatlamba range, a continuous chain extending between the 27th parallel and the beginning of the delta of the Zambesi, 300 m. from the Mozambique channel, with an elevation varying from 4,000 to 10,000 ft. The Drakenberg is that portion of this range which borders the colony of Natal. At the head of the delta it widens into a belt of fertile highlands, and from this spot other mountain chains branch forth in various directions; one westward, one northward toward Lake Nyassa, and the Lupata mountains southward along the coast of Sofala at a distance of 160 m. from the sea. The northward range is distinguished by no important peak S. of the 4th parallel; but between lat. 3° and 4° S., some 200 m. from the Indian ocean, rises the beautiful snow-capped summit of Mt. Kilimanjaro, 20,065 ft. high, and believed to be the loftiest mountain in Africa. It has lately been partially ascended by the Rev. Charles New, an Englishman, who

reached the snow line, and who describes its lower slopes as covered with forests of gigantic trees, above which are rich growths of heath and pasture. About 200 m. further N. Mt. Kenia also rises into the region of perpetual snow, its altitude being estimated at 17,000 ft. A continuous chain is believed to connect this range with Abyssinia. The Abyssinian system of mountains comprises numerous lofty summits clustered in groups on the elevated plateau which separates the Nile basin from the E. African coast. This table land sinks abruptly to the lowlands on the edge of the Red sea, but descends by much gentler gradations on its W. slope. The dividing ridge of the watershed averages 8,000 ft. in height; on the north it is considerably lower, while it ascends to 11,000 ft. on the south. There are said to be peaks over 15,000 ft. high in the Simen range, and in other parts of the country there are known to be many higher than 12,000 ft.—Africa has long been regarded as distinctively and pre-eminently the country of deserts. The Sahara extends over almost all the northern portion of the continent between lat. 15° and 30° N. With an average width of 1,000 m., and an extreme length of 3,000 m., it stretches from the Nile to the Atlantic, and from the southern slopes of the Atlas to Soodan, covering an area which exceeds that of the Mediterranean, and with a surface in some places below the level of that sea. The southern limits of this vast land of desolation have never been continuously traced by Europeans, and our knowledge of its trackless wastes is confined to the ancient lines of caravan travel across them. The surface is made up of shifting sand, rough gravel, and barren rock, variously distributed, and occasionally traversed by low chains of bare hills. Extensive plains of salt also occur. Throughout this sterile region rain is almost unknown, and the heat is terrific. At the equinoctial seasons the easterly wind, which blows during three fourths of the year, rises at times to a gale, and causes the terrific sand storms by which caravans have so frequently been overwhelmed. The western portion of the Sahara, called Sahel, is the wildest and most desolate; in the eastern portion, to a part of which the name Libyan desert is applied, are numerous oases. These differ greatly in extent, but all contain springs, rich grass, and date palms. Many of them are depressions below the surface of the surrounding desert. Some consist of little more than a well of fresh water, a clump of trees, and a spot of verdure; others cover many miles of fertile country. The more important are: the Great Oasis, or oasis of Thebes, 120 m. long and about 5 m. wide; the Lesser Oasis, smaller but similar in outline; the oasis of Darfoo, constituting the monarchy of a sultan; the oasis of Siwah, in which are the ruins of the famous temple of Jupiter Ammon; and the oasis of Fezzan, with the town of Moorzook as its capital. All of these except the last are situated in a furrow-like depression,

parallel to the Nile, intersecting the Libyan desert in its gradual descent toward the Mediterranean. The dreaded wind known as the simoom is a terrible scourge of the desert and the neighboring countries. It is due to the high temperature, sometimes 200° F., attained by the surface sand of the desert under the influence of the vertical rays of the sun pouring down upon it through an intensely dry atmosphere. The furnace-like wind to which this gives rise is rendered still more terrible by the particles of burning sand with which it is impregnated and which tinge the atmosphere with the reddish hue characteristic of the simoom. Burkhardt in 1813 recorded 122° F. in the shade during the prevalence of this pestilential blast, and 114° was observed in 1861 by Sir Samuel Baker. Many other winds of the same class blow from the desert; among them the parching sirocco, which sweeps from northern Africa over Sicily, southern Italy, and Syria; the khamsin, which blows in Egypt for 50 days between the end of April and the summer solstice; the harmattan, which prevails at regular intervals between November and February throughout Senegambia and Guinea, coming from the western Sahara; and the withering N. W. wind which occasionally visits Natal and the Cape. The great desert of southern Africa is the Kalahari, extending from the Orange river on the south to the 20th parallel of S. latitude, and from the pastoral Namaqua district on the west to a strip of pasture land which is believed to border the inland slope of the Quatlamba mountains. Its average elevation above the sea level is only 600 ft. Although termed a desert, the Kalahari is not wholly destitute of vegetation; indeed, light grass, an abundance of tuberous plants, and extensive patches of bushes are found in many localities. Rain seldom refreshes any of these arid tracts; but when it does, they are at once carpeted with the richest verdure.—Before the explorations of Dr. Livingstone, southern Africa was believed to be a sterile wilderness, in the equatorial climate of which the existence of an abundant animal or vegetable life was impossible. In 1852, however, Sir Roderick Murchison, in an address to the royal geographical society of London, advanced the hypothesis that the whole African interior would prove to be a vast watery plateau of some elevation above the sea, but subtended on the east and west by much higher grounds. This view was based purely on geological reasoning, for at that time absolutely nothing was known of the interior N. of Lake Ngami; it was a blank on the map. Livingstone was then engaged in his first expedition on the Zambesi, and its results triumphantly confirmed the correctness of Murchison's speculations. A labyrinthine network of rivers extends over the whole table land between the 10th and 20th parallels, so that the natives call the region Linoka-noka, or "rivers upon rivers." S. of the Kalahari desert the Gariep or Orange river is the only considerable stream.

It flows along the northern boundary of the Cape region westward into the Atlantic ocean, but is not navigable in any part of its course, being an impetuous torrent during the rains, and in the dry season little more than a narrow, slow, and shallow current. Of the rivers which flow into the Indian ocean, the Zambesi or Leambye exceeds all others in magnitude and importance; its name signifies "the river," and indicates its preëminence in the native mind. From its origin among the Gilolo hills to its junction with the Chobe river, in lat. $18^{\circ} 17' S.$ and lon. $23^{\circ} 50' E.$, the general course of the Zambesi is from N. to S., but below this point it flows eastward, making a semicircular bend to the N. on its way to the sea. The area of its drainage basin extends through 10° of latitude and more than 21° of longitude. At the Victoria falls, in lat. $17^{\circ} 57' S.$, lon. $26^{\circ} 6' E.$, the river narrows from a width of 1,000 yards to a gorge-like channel in the rock about 75 ft. broad, and leaps down a distance of 300 ft., forming one of the most magnificent and beautiful cascades in the world. The rising spray forms a constant cloud above the cataract. On the upper portion of the Zambesi the adjacent country is low, and villages are built on raised ground to protect the inhabitants against the annual overflow. Further down, the river is a mile wide in many places. It becomes less rapid after descending the falls, and at the commencement of its delta, 300 m. from the Mozambique channel, it is wide and tranquil. The extreme length of the delta and its shallowness except in the main branch render access from the Indian ocean rather difficult. The Limpopo, which reaches the E. coast about midway between Delagoa bay and the tropic of Capricorn, is a river famed among sportsmen for the gigantic game which haunts its banks, but worthless as an avenue to the interior on account of its deficient depth and the shoals at its mouth. The Congo is the southernmost of the great rivers of Africa which descend from the plateau on the Atlantic side. Of its course or character in the interior we have but little authentic information, although it is supposed to be connected with the Kasai, which is said to traverse a country of alternate forest and pasture land. It is navigable in its lower course, where it is 5 m. wide and of great depth; but at the distance of 160 m. from the sea there is a cataract. The only notable river between this and the delta of the Niger is the Ogowai, which crosses the equator, and enters the sea by the same outlet as the Fernan Vaz. The remarkable facilities which it is altogether probable are furnished by the Niger for direct water communication with the most populous regions of central Africa, render it by far the most important river of the western coast. Precisely where it rises is unknown, but the Bambarra country, among the Kong mountains in Senegambia, about 1,300 ft. above the sea, has been fixed upon as the most probable locality. Its course from its source to the gulf of Guinea

is very tortuous, traversing some 15 degrees of longitude, and an estimated distance of 2,500 m., and making a great bend to the north in the vicinity of Timbuctoo. It is variously known as the Niger, the Quorra, and the Joliba. The river Telhadda, from the heart of Soodan, is the largest tributary; below its embouchure the Niger expands to a great width, the distance from bank to bank sometimes exceeding 6 m. The delta through the innumerable streams of which its waters flow into the bights of Benin and Biafra, is equally famous for its luxuriant vegetation and its deadly climate. Rising like the Niger in Senegambia, but draining the western declivity of the watershed of that country, the Rio Grande, the Gambia, and the Senegal find their way to the Atlantic through a wall of coast mountains which forms an obstacle to extended inland navigation on these rivers. The Senegal is the largest, and is more than 800 m. in length. Of all African rivers, however, the Nile is at once the most famous and the most wonderful. It is remarkable physically for the unfailling inundation by which a rainless country is annually fertilized; it is remarkable politically for the early and elaborate civilization which has left imperishable monuments along its valley; and it is remarkable geographically for its vast length, which probably exceeds that of any other river, and for the problem concerning its sources, which remained unsolved until the third quarter of the 19th century. The explorations of Baker have fixed the great Albert lake, which lies directly under the equator, as a proximate source, at least; whether a more remote origin exists can only be determined by future geographical research. The Bahr-el-Abiad, or White river, as the main stream of the Nile is called, issues from the northern extremity of this lake, between lat. 2° and $3^{\circ} N.$, at an altitude of 2,720 ft., and flows northward through a mountainous and rocky region, over four cataracts, to Gondokoro, in lat. $5^{\circ} 54' N.$ Here it emerges into a plain and becomes navigable without serious interruption as far as the upper Nubian cataract. Near lat. $9^{\circ} 30' N.$ it receives the tributary Bahr-el-Gazal from the west—an important river, not yet fully explored. The Blue Nile, or Bahr-el-Azrek, from the lofty plateau of Abyssinia, joins the White river at Khartoom; and still further N. it receives the Atbara from the same country. Below this point tropical rains are unknown, and not a single tributary, not even a riveulet, enters the Nile. For more than 1,000 m. it alone irrigates the long green valley which without it would be as barren as the bordering desert. In Nubia it descends over three successive falls, each of which is in reality merely a series of rapids, and which are known respectively as the first, second, and third cataracts, the first named and northernmost being at Syene, on the boundary between Egypt and Nubia, about 700 m. from the Mediterranean and 600 ft. above its surface. The delta begins 90 m. from the sea,

by the separation of the river into the Rosetta and Damietta branches. The width of the Nile differs greatly in different sections; there are many places where it is several miles broad. The average velocity of its current is $2\frac{1}{2}$ m. an hour. In Egypt the maximum height of the annual flood is between 30 and 35 ft., and is attained between the middle of September and the middle of October, the river being lowest in April and May.—The lakes of Africa are closely associated with the continental river systems, especially in the case of the Nile. That river proceeds from a region of fresh-water lakes unrivalled except by the great lakes of N. America. Three of these lakes have been visited by Europeans, but no one of them has been completely explored. In 1858 Lake Tanganyika (so called from a native word meaning the meeting place of waters) was discovered by R. F. Burton and J. H. Speke, captains in the British army, whose names have since become famous in the history of African exploration. It is a long and narrow sheet of water, situated between lat. $3^{\circ} 10'$ and $7^{\circ} 50'$ S., with its centre in about lon. 30° E., according to most of the authorities, although Kiepert places it considerably W. of that meridian. Burton estimates its total length at 250 m., its mean breadth at 20 m., and its altitude above the sea at 1,850 ft. Its waters are pure and deep. The Victoria N'yanza, which was seen by Speke in 1858, and subsequently visited by him in company with Capt. Grant, lies some 200 m. N. E. of Lake Tanganyika, with a lofty mountain district intervening. Among its native names are Nyanja, Ukere, and Ukerewe. According to Speke's observations in 1862, its height above the ocean is 3,308 ft. Its northern outlet, which flows over a picturesque cataract called Ripon Falls, in the immediate vicinity of the lake, was believed by Speke to be the veritable White Nile, although he was told by the natives that this stream passed into another vast inland sea, which they called the Luta Nzigé. This statement was confirmed by the discoveries of Sir Samuel Baker and his wife in 1864, when they traversed the eastern shores of the Luta Nzigé—on which they bestowed the name Albert N'yanza—traced its connection with the Victoria lake on the east, and beheld the Nile emerging from it on the north. This vast expanse is embosomed amid noble mountains of great beauty, and is 2,720 ft. above the level of the sea—much lower than the Victoria N'yanza. Its area is unknown, though Baker estimated its width near the northern end at 60 m. Still another lake belonging to this aggregation and called Bahuri Ngo, or Baringo, is supposed to lie E. of the Victoria N'yanza. Capt. Burton persistently asserts a belief that the latter will ultimately be ascertained to be, not a single lake, but a vast marshy region of many lakes. Far removed from this system, in lat. $20^{\circ} 19'$ S. and lon. 22° E., is Lake Ngami, about midway between the respective coasts of the continent. It is 3,713 ft. above the ocean, from 50 to 70

m. long, quite shallow, and supposed to be gradually contracting its shores. Livingstone discovered it in 1849, and followed its outlet, the river Zooga, some distance toward the district now known to be watered by the Limpopo. Ten years later Livingstone also discovered the more important Lake N'yassa, which is situated about 300 m. from the E. coast and N. of the Zambesi delta, with which it is connected by the river Shiré. It lies in a valley surrounded by eminences, at a height above the sea of about 1,500 ft. Its width is from 20 to 60 m., and its entire length is estimated at not less than 200 m., although the northern extremity has never yet been visited by white men. Its waters are very deep. In the clear, dry season their surface is ruffled by boisterous southeasterly gales, which render navigation perilous. Shirwa, a much smaller lake than N'yassa, but exceeding it in elevation by about 500 ft., is situated among the mountains on the S. E., 30 m. distant. The principal lake of Abyssinia is Tsana or Dembea, covering an area of 1,400 sq. m. in the centre of a plain over 6,000 ft. in altitude, on which the climate is that of perpetual spring. In the same country is also the beautiful little lake of Ashangi, enclosed on all sides by mountains towering above the plateau on which it rests. The chief body of water in central Africa is Lake Tchad, which is extremely shallow, being only from 8 to 15 ft. in depth. Its area appears to vary somewhat in different seasons. Its elevation above the sea is 840 ft.—The geology of Abyssinia is better known than that of any other single region of Africa. The foundation of the plateau is metamorphic rock extending to a height of some 8,000 ft. above the sea, and surmounted principally by bedded traps, although in a few instances limestones and sandstones are enclosed between these formations. A line of rocks of volcanic origin skirts the Red sea coast, along which there is also a fringe of coral, embracing Massowa and the neighboring islands. The precipitous gorges through which so many of the Abyssinian rivers flow have probably been worn down through the solid rock to their present depth by the ceaseless action of water exerted through enormous periods of time. The ravine of the Tacazze, one of the streams which unite to form the Blue Nile, is 3,000 ft. deep. A firm clay underlies the deserts of N. Africa. On the W. boundary of Egypt limestones occur, and granite, sandstone, and argillaceous slates are found in Nubia. The deltas of all the great rivers are alluvial deposits. The geological structure of the S. African tableland, according to Murchison, is unique in having maintained the same terrestrial and lacustrine conditions since the secondary epoch. No fossil bones have been found in this territory except such as belong to species of animals which still inhabit it. There are tertiary rocks at the Mombas mission in Zanzibar, near the mouth of the Zambesi, and at the Cape; but these

are coast formations distinct from those of the interior, in which marine fossils have been sought in vain. Every known fact connected with the geology or palæontology of this region indicates that it has remained practically unchanged through ages which have witnessed the rise and fall of other continents. Within its borders all traces of glacial drift are absent; and there are no volcanic mountains except the Cameroons near the W. coast, and Mt. Kilimanjaro, which has probably been inactive since prehistoric times. The precious metals do not seem to be very generally distributed throughout Africa, and, so far as at present known, the mineral productions are neither abundant nor varied. Until the discovery of gold in Australia and California, however, the gold fields of Guinea, in the Kong mountains, were esteemed as among the most important sources of the world's supply. Iron and copper occur in many parts of inter-tropical Africa, and Livingstone found seams of coal cropping out along the banks of the Zambesi. Salt is said to be plentiful in almost every country on the continent. Extensive diamond fields, producing many stones of fine quality and great size, were discovered in 1867 in the districts N. of the Orange river and near its confluence with the Vaal. Some controversy arose between the authorities of Cape Colony and the government of the neighboring Orange Free State as to which was entitled to exercise jurisdiction over this territory, and was finally settled in favor of the British claim. The diamond called "the Star of South Africa," which was found shortly after the opening of the diggings, was sold in its rough state for £11,500 sterling.—Among the distinguishing features of the fauna of Africa may be noted the numerical preponderance of terrestrial over aquatic species of mammals; the large proportion of quadrupeds exclusively African in their origin or habitat; and the number of gigantic pachyderms. Considered with reference to the geographical distribution of animals, Africa is partially included in each of two great provinces recognized by naturalists: the paleo-arctic region, which comprises nearly all northern Asia and the African continent N. of the Sahara, and the Ethiopian region, containing the remainder of Africa and the whole of Madagascar. The affinities between the existing and fossil animals of S. Africa and India strongly indicate that these now widely sundered countries must once have been connected with each other more intimately than at present. Two of the three known genera of anthropoid apes, the chimpanzee and the gorilla, are found only in Africa. The habitat of the chimpanzee comprehends the whole western region between the Sahara and the Congo river, but that of the gorilla is limited to the tropical delta districts on the Atlantic seaboard near the equator. Baboons, with one or two exceptions about which there is some doubt, are also confined to Africa.

Everywhere in Abyssinia is found the great dog-faced baboon (*Cynocephalus hamadryas*), remarkable for its long hair. These monkeys traverse the country in bands numbering from 200 to 300, with a venerable male at the head of the line of march. The galagos of Senegal, Gambia, S. Africa, and Sennaar are the continental representatives of the lemurs of Madagascar. Of the rhinoceros there are five African species, all with two horns, and all restricted to the region S. of the Great Desert, the two white species never having been encountered N. of the equator. The range of the elephant (*Elephas Africanus*), which differs from its Asiatic congener, and has never been domesticated like him, is similarly limited. Multitudes of hippopotami are met with on the Nile, the Niger, the Senegal, and in nearly all the equatorial rivers and lakes, the animal being peculiar to the continent. Sir Samuel Baker saw immense herds of them in the Albert N'yanza. Among the pachydermata are also the hyrax and the wart hog. In Bornoo, Abyssinia, and the Galla country, the ox is remarkable for the extraordinary size and length of his horns. Buffaloes are numerous, and the Cape variety is quite fierce and formidable. The giraffe or camelopard, perhaps the most singular of African ruminants, and found in no other land on the globe except as a fossil, is a timorous creature of gregarious habits, which roams over the interior beyond the Orange river, in flocks seldom amounting to 100 in number. The zebra and quagga abound in S. Africa. Five sixths of the known species of antelopes are said to be natives of Africa; of these, the most noteworthy are the eland, the springbok, the klipspringer, and the Abyssinian Beni Israel (*A. saltiana*), one of the smallest of antelopes, a specimen measured by Blanford being only 1 ft. 4 in. high at the shoulder. The more ferocious carnivora abound. The lion, although somewhat circumscribed in his range, is still found in the Atlas mountains on the north, and throughout a great portion of the table land. According to Dr. Kirk, every tribe has a name for him. The tiger is not found in any part of Africa, but leopards, panthers, and the smaller cats are common, as also are hyenas, jackals, and foxes. It is worthy of note that the domestic cat is exceedingly rare in Africa. The single-humped camel is the most useful of the domesticated animals, being almost indispensable for the performance of the long desert journeys to which it is so perfectly adapted. Tame goats and several varieties of coarse-wooled sheep are numerous in certain districts. The birds of N. Africa are almost identical with those of Europe, but the ornithology of the torrid section is represented by some forms of uncommon interest, such as the ostrich, the guinea fowl, and the serpent-slaying secretary bird. The ostrich inhabits the deserts and adjacent plains throughout the interior, and is also met with in Arabia, which is the only country of Asia where it occurs.

Innumerable flocks of guinea fowls haunt the underbrush on the river banks within the tropics and on the island of Madagascar. Among the smaller birds are the little honey bird of Cape Colony, several peculiar species of parrots, many magnificently colored kingfishers, and the indicator family, so called from the assertion of the natives that the birds belonging to it invariably lead the follower of their flight to bees' nests. In Egypt is found the sacred ibis of the ancients, and many other water birds frequent the streams and lake basins. Reptiles are everywhere abundant. The proportion of venomous serpents to those which are harmless is greater than elsewhere, and the enormous python of the tropics, corresponding to the American boa, is sometimes 25 ft. long. The true crocodile is found all along the Nile up to an elevation of 4,000 ft. above the sea; lizards and chameleons are also very plentiful. Africa is richer in tortoises than all the other regions of the globe combined. The celebrated tsetse fly of S. Africa, which fortunately is restricted to limited districts, is one of the most noxious of known insects, its bite being inevitably fatal to horses, cattle, and dogs, but, singularly enough, productive of no injury to the mule, the ass, wild animals, or man. The locust from time immemorial has been the scourge of the agricultural territories. The termites, commonly but erroneously called white ants, dwell in dome-like hills of clay, which they raise to a height of ten feet and upward, on the W. coast, being careful to build them above the high-water mark of the yearly floods.—The flora of the northern part of the continent appears to differ essentially from that of the Niger, and the Cape may be regarded as a botanical province differing from them both. A considerable majority of the plants found in the territories bordering the Mediterranean are common to Europe. In all the green places of the desert grows the date palm, with its abundance of rich fruit and grateful shelter. Egypt produces the famous lotus, Senegal the mighty baobab and curious *pandanus candelabrum*, Guinea the valuable oil-yielding palm, and Cape Colony many species of finely colored aloes. Immense tracts of thorny thicket cover the E. frontier of the latter country, and from them is derived the name Bosjesmans or Bushmen, applied by the Dutch boers to the natives who dwell there. Nearly every attempt to introduce the cereals of other zones and regions into tropical Africa has been rewarded with success. Maize, coffee, indigo, rice, and tobacco flourish, and excellent cotton has been raised on artificially irrigated soil in Egypt. The character of the vegetation varies of course with the elevation above the sea and the distance from the equator.—The entire absence of trustworthy statistics is a serious obstacle to a correct estimate of the aggregate population, which has been placed by some authorities as high as 200,000,000, and by others as low as 100,000,000. The ethnological classifi-

cation of the native races also presents many difficulties, especially since the scientific accuracy of the old division of the human family into the Caucasian, the Mongol Tartar, and kindred groups, has been impeached. Under that system the inhabitants of Africa N. of the 20th parallel of N. latitude were regarded as belonging to the Caucasian variety, which included therefore the Moors, the Arabs, the Berbers, the Copts, and the Egyptians. Except the Abyssinians, who are also said to be of Caucasian origin, all the nations and tribes S. of the same parallel belong to the Ethiopian stock, and exhibit the black color, high cheek bones, thick lips, and woolly hair which distinguish it. They comprise the negroes proper, who occupy Soodan, Senegambia, the Guinea coast, and the interior; the degraded Hottentots and Bushmen; and the tall and warlike Caffres and Gallas. There are many other subdivisions.—Of the political divisions of Africa, Egypt is certainly the oldest. It embraces an area of about 200,000 sq. m., situated on both sides of the Nile N. of lat. 24° N., and since 1517 has been a dependency of the Ottoman empire under the sway of a viceroy, now known as the khedive, who is virtually an independent monarch. The population of the country, including the dominant Turks, is over 5,000,000 according to the Egyptian officials, but in reality is probably much smaller. Alexandria is the chief seaport, and contains 238,000 inhabitants. The Suez ship canal, from Port Saïd on the Mediterranean to the gulf of Suez on the Red sea, was opened in 1869. Cairo, the capital, has a population of 300,000. Mohammedanism is the prevailing religion. The whole northern coast W. of Egypt is denominated Barbary, and comprehends Tripoli, Tunis, Algeria, and Morocco. Tripoli is a tributary province to Turkey, under the rule of a governor general appointed by the sultan, and is situated between Egypt and Tunis, having an area variously estimated at from 61,760 to 105,000 sq. m., and a population of 1,500,000. The capital, bearing the same name, is a seaport town of 30,000 inhabitants. Barca and the oasis of Fezzan are subject to the Tripolitan government. Tunis, the adjoining state on the west, is likewise a Turkish dependency, also with a capital of the same name. It covers 50,000 sq. m., and the population numbers 2,000,000. The city of Tunis is about 13 m. S. E. of the ruins of Carthage. The ruler bears the title of bey. Algeria, formerly called Algiers, is a French colonial province, having been conquered from the Turks in 1830. There are 2,900,000 inhabitants, 200,000 of whom are Europeans. The estimated area is 170,000 sq. m. Morocco, the westernmost and largest of the Barbary states, is an empire under the independent and absolute rule of a sultan, who resides sometimes in the city of Morocco and sometimes in Fez. His dominions extend over more than 200,000 sq. m., with a population of from 3,000,000 to 5,000,000, composed mainly

of Moors. Tangier is the leading seaport, and in European wars has frequently been resorted to as a convenient and secure naval station. The W. coast of Africa, from the Sahara to Cape Negro, comprises three divisions known as Senegambia, Upper Guinea, and Lower Guinea, each of which contains a number of native states and various European colonial establishments. Thus the English have Gambia on the river of the same name, with the main settlement at Bathurst; Sierra Leone, a peninsula 18 m. long and 12 m. broad, with a white population in 1867 of 129 persons; Gold Coast, a territory of 6,000 sq. m. in Upper Guinea, with its principal fort at Cape Coast Castle; and Lagos, 250 m. from the Niger, a station established to secure the more complete suppression of the slave trade. The French colonies are: Fort St. Louis, at the mouth of the Senegal river; Goree, just S. of Cape Verd; Grand Bassam, on the Ivory Coast; and Assinie, on the Gold Coast. There are also several Danish and Dutch settlements in Guinea; but by a treaty completed in 1872 the latter were transferred by the government of the Netherlands to the British crown. Liberia, a republic founded for emancipated negroes from the United States, occupies a portion of the coast N. W. of Cape Palmas. The most prominent and powerful native states of Upper Guinea are the Ashantee territory and the kingdom of Dahomey. In Lower Guinea the Portuguese, who occupy many important towns, exercise supremacy over about 300,000 of the inhabitants, and there are also four independent negro sovereignties, Loango, Congo, Angola, and Benguela. Cape Colony is the largest of Great Britain's possessions in Africa, and since 1866 has included British Caffraria, which was formerly under a separate government. It was conquered from the Dutch in 1806, and now extends over an area of about 200,000 sq. m., having a population in 1869 of 566,158 souls, among whom there were 187,439 Europeans. A short railway runs from Cape Town into the interior as far as Wellington. Natal, also an English colony, owes its name to the fact that land was discovered here on Christmas day in 1497 by Vasco da Gama. Its seacoast of 170 m. is penetrated by only one good harbor, which is at D'Urban or Port Natal, and even this will not admit the largest vessels. The Orange Free State and Transvaal Republic are two democratic governments organized by malecontent boers and others who were dissatisfied with the British colonial rule. N. of the Cape countries the E. coast is divided into three parts: Mozambique, under Portuguese dominion; Zanguebar, in which the principal town is Zanzibar, governed by the sultan or imam of Muscat; and Ajan, a wild tract extending to Cape Guardafui and inhabited by the Somauli. Far to the north and west lies Abyssinia, where a debased form of Christianity is generally professed, and has been to some extent the established religion

for many centuries. Nubia, which connects Abyssinia with Egypt, has been subject to the viceroy of the latter country since 1822. The population is Mohammedan. Comparatively little is known concerning Soodan, a name which is applied to the vast land of central Africa bounded N. by the Sahara, W. by Senegambia, S. by Upper Guinea and the table land, and E. by Darfoor. Among its kingdoms are Bornoo, Haussa, and Wadai; and the celebrated cities of Sackatoo and Timbuctoo are within its boundaries.—To the ancients all of Africa except Egypt and the northern coast was known as Libya. Herodotus says that an expedition circumnavigated the continent in the reign of Pharaoh Necho, and there are traditions of Carthaginian exploration far inland; but whatever knowledge was gained by these efforts had been lost to the world long before the voyages of those Portuguese navigators of the 15th century who followed the entire coast from Egypt to the Indian ocean, and led the way for the numerous colonies of Portugal afterward established upon it. Vasco da Gama was the most distinguished of these discoverers, and was the first to double the Cape of Good Hope, which he did on Nov. 20, 1497. He continued his voyage in African waters as far as Mombas, and then proceeded to India. Many of the expeditions of the earlier epoch were sent out under various commanders by Prince Henry the Navigator. The French colonization of the W. coast dates from the 17th century; the Dutch East India company founded its first post at the Cape in 1650; and the African company, incorporated by the English parliament in 1750, did not long delay the establishment of trading stations in Guinea. In 1772 Bruce, the Scotch traveller, visited the sources of the Blue Nile, and after exposure to the utmost hardship and greatest danger returned to England to find his plain and truthful narrative discredited on every hand. Mungo Park, also a Scotchman, was killed on his second trip to the Niger in 1806, after reaching Timbuctoo. The important expedition of Denham and Clapperton to Bornoo set out from Tripoli in 1822, and resulted in numerous discoveries. They were the first white men who ever saw Lake Tchad. In a subsequent attempt to trace the course of the Niger up from the coast Capt. Clapperton died at Sackatoo in 1827, having in his two journeys travelled over the entire distance between Tripoli and Cape Coast Castle. Soodan has since been much more thoroughly explored by Barth, Vogel, and Overweg, and the Niger by the brothers Lander, one of whom had been Clapperton's servant. Our earliest knowledge of the S. African interior came from adventurous native merchants who were bold enough to cross from Loanda on the Atlantic to the shore of the Mozambique channel; and since 1849 the almost uninterrupted journeys of Dr. Livingstone over the great plateau have copiously increased our information in regard to it

by such discoveries as those of Lake Ngami, Lake N'yaasa, and the Victoria falls of the Zambesi. The explorations of Speke, Baker, and Burton have already been mentioned in connection with the sources of the Nile; and the travels of Petherick on the Bahr-el-Gazal, and of Du Chaillu in equatorial Africa, should not be forgotten. Sir Samuel Baker has recently been commissioned by the khedive to destroy the slave trade and extend the authority of Egypt on the upper Nile, and furnished with a military force for that purpose.

AFRICA, Languages of. The languages of Africa fall into five groups: 1. The Semitic idioms of Abyssinia, exhibiting special relations with the Himyaritic of southwestern Arabia, from which region the Abyssinians are unquestionably immigrants, across the strait of Bab-el-Mandeb. One of these idioms, the Ethiopic or Geez, was long a language of literary cultivation, under Christian influence, and possesses a considerable body of literature. More recently, the Amharic, a kindred dialect, has been the official and learned language of the country. 2. The Egyptian and the dialects related with it. Between these and the Semitic there are generally held to exist evidences of an ultimate but exceedingly distant connection. The Berber language (descendant of the ancient Libyan), occupying, except so far as it has been displaced by the Arabic, the whole north of the continent, and a group of dialects south of Abyssinia, of which the Galla is the most prominent member, are the other relatives of the Egyptian. 3. The Hottentot and Bushman dialects, in the extreme south. Bleek has within a few years declared that these are branches of the Egyptian group, and that those degraded communities, almost the lowest and most savage of men, are therefore a fragment from the same stock which produced the culture of Egypt; and many linguistic and ethnological writers have accepted his view, but the most recent authorities reject it. 4. The South African group or family, sometimes called the Caffre, or Zingian, or Bantu. This fills the whole southern part of the continent (except the territory of the preceding group), and is made up of a considerable number and variety of dialects — the Zulu, Sechuana, Suaheli, Mpongwe, &c.—all plainly and closely related. Its most striking peculiarity is its prevailing use of prefixes instead of suffixes; a word without a formative prefix is as rare here as in the older languages of our own family one without a suffix; and the grammatical agreement of words is in their prefixes, or alliterative, instead of in their suffixes, or rhyming. A phonetic peculiarity shared by some of the dialects of this group with those of the preceding is their use of clicks, or sounds made with the tongue by suction, as consonants composing words. 5. There remains a broad band across the middle of the continent, filled with a large number of widely diverse languages—so diverse that between them, for the most part, no con-

nections can be clearly traced; although, as sharing to a certain degree the peculiarity of formation by prefixes with the South African family, they are probably ultimately related with the latter and with one another. Conspicuous among them are the Borno, Haussa, Mandingo, Grebo, Yoruban, and Foola.

AFRICANUS, Sextus Julius, a Christian writer of the 3d century. Though of African birth or descent, he lived in the city of Emmaus, Palestine, of which, in a mission to Rome about 220, he procured the rebuilding after it had been burned. The new city was called Nicopolis. He is said to have been afterward a bishop. He composed a *Chronicon* in five books, commencing with the creation and closing with the year 221 of the present era, fragments of which have been preserved by Eusebius, Syncellus, and others. Two letters by him are also extant.

AFZELIUS. I. Adam, a Swedish naturalist, born in West Gothland, Oct. 18, 1750, died Jan. 30, 1836. He was a pupil of Linnæus. In 1792 he visited the English colony of Sierra Leone, and made some valuable collections illustrating the botany of the west coast of Africa. After his return in 1794 he was secretary of the Swedish embassy at London, and in 1812 became professor of materia medica at Upsal. He wrote several works on botany, and published the autobiography of Linnæus. **II. Arvid August**, a Swedish author, born at Brod-detorp, May 6, 1785, died in Enkköping, Sept. 25, 1871, where he was pastor for 49 years. With Geijer he published *Svenska Folkvisor* ("Swedish Folk Songs," 3 vols., Stockholm, 1814-'15), of which a selection appeared in German (Berlin, 1830). He is also the author of a collection of original poems in the style of the ancient ballads, wrote a tragedy, translated into Swedish the *Hervarar Saga* and the *Sämundar Edda*, and prepared with the assistance of Rask an Icelandic edition of the latter. His principal work is *Svenska Folkets Sagahäfter* (1839-'70), ending with Charles XII. Ludwig Tieck wrote a preface to Ungewitter's German translation of the first 3 vols. of this work (*Folkssagen und Volkslieder aus Schwedens älterer und neuerer Zeit*, Leipsic, 1842).

AGA, originally the appellation of an elder brother, now a title of distinction, among the Turks and Tartars. The aga of the janissaries was the commandant of that corps. The title is also given to wealthy men of leisure.

AGADEZ, the capital of the sultanate of Air or Asben, Africa, in lat. 16° 40' N., lon. 7° 30' E., about 400 m. N. W. of Lake Tchad; pop. about 8,000. It is believed to have been founded at the end of the 15th century by Berbers, as an entrepôt for their commercial intercourse with the capital of the Songhay empire. The principal article of trade was gold, the town having its own standard weight, which still regulates the circulating medium. But the commerce of the present day is inconsiderable, and its chief importance to the world

consists in its lying on the most direct road to Sackatou and contiguous parts of Soodan.

AGADIR, the southernmost seaport town of Morocco, on the Atlantic, in the province of Sûs, 23 m. S. E. of Cape Ghir, in lat. 30° 26' 35" N., lon. 9° 35' 56" W.; pop. about 600. It has the best harbor in Morocco, and was formerly a large and strongly fortified city; but in a revolt against Sidi Mohammed in 1773 it was captured and nearly destroyed, and the inhabitants were transferred to Mogador. In the 16th century it was held by the Portuguese and called Santa Cruz.

AGAMEMNON, king of Mycenæ, one of the foremost figures in the Iliad, was the son of Atreus according to Homer, but his grandson according to others. He commanded the combined forces of Greece at the siege of Troy. He married Clytemnestra, half sister of Helen, the wife of his brother Menelaus. The Grecian fleet being detained at Aulis, its sailing place, by unfavorable winds, the priest Calchas declared that the gods must be propitiated by the sacrifice of the king's daughter Iphigenia, on account of his having offended Diana by killing her favorite stag. Agamemnon yielded to the will of the gods, but his daughter was saved by Diana. His quarrel with Achilles forms one of the most interesting portions of the Iliad, which opens with an account of it. On his return from Troy he was murdered by his wife, who had formed an adulterous relation with Ægisthus during his absence, and avenged by his son Orestes.

AGAMI (*psophia crepitans*), a bird of tropical America, also termed the gold-breasted trumpeter. It has been classed among the cranes,

Agami, or Gold-breasted Trumpeter.

but subsequently among the pheasants. By Temminck it is classed as the first genus in the order *alectorides*. Its body is about the size of the pheasant, to which it bears some resemblance in its plumage; but it is much higher on its legs, which resemble those of the *gral-*

latores or wading birds, being naked far above the knee. It has also a long neck, and in all respects, at first sight, has the appearance of a water fowl; but it never visits fens or water margins, frequenting rather the uplands and dry mountains. Its breast is of a beautiful iridescent green and gold, in which, as in the bare space of scarlet skin which surrounds its eye, it resembles the pheasant. Its tail, however, is short, and partially covered by the loose silky plumes of its light-colored scapularies. It is easily domesticated, and becomes attached to its master, whom it will follow about like a dog. Its name of trumpeter (*psophia*) is given on account of its remarkable cry, performed, with the bill closed, by aid of a peculiar conformation of the larynx. The agami, like the rest of the *alectorides*, makes no nest, but deposits its eggs, which are of a light green color, to the number of 10 up to 16, in a hollow place scratched at the foot of a tree. The down remains very long on the young bird, and then changes into long, close, silky plumes.

AGANIPPE, in ancient geography, a fountain of Bœotia, near Mount Helicon, flowing into the river Permessus. It was believed to have the power of inspiring those who drank of it, and was sacred to the muses, who hence derived their name Aganippides. In mythology, Aganippe was a nymph, the daughter of the river god Permessus.

AGAPÆ (Gr. ἀγάπη, plur. ἀγάπαι, love; generally used in the plural), feasts of love, originally a simple meal, taken by the primitive Christians, at first in their places of worship and in connection with the eucharist. It usually followed the sacrament, but there is reason to suppose that it sometimes preceded it, especially in the earliest times. Extravagance and disorder seem to have been early introduced at these feasts in some places, and were rebuked by St. Paul in 1 Cor. xi. In the 2d century the eucharist came to be commonly celebrated alone. The agapæ were suspected by the Roman government as scenes of secret intrigue. They were regulated by various councils down to the 9th century, and gradually disappeared. In modern times they have been revived, under the name of love feasts, by the Moravians and Methodists.

AGAPEMONE, or **Abode of Love** (Gr. ἀγάπη, love, and μονή, abode), an establishment at Charlynch, Somers-shire, England, about 9 m. from Taunton, where a number of persons associated themselves together in 1816 under the name of "Family of Love," and under the guidance of several clergymen, the principal of whom are Henry James Prince and a Mr. Starkey, the former allowing himself to be addressed as "the Lord." The prevailing idea of the sect is that perpetual enjoyment is the sole aim of spiritual and material existence. The relations between the sexes, however, are said to be governed by mutual affinities and attractions, but members of the family of love maintain matrimonial unions while the attrac-

tion lasts, and polygamy is forbidden. The life at the Agapemone soon became a matter of public notoriety in consequence of a lawsuit for the custody of a child between a Mr. and Mrs. Thomas, two of Prince's converts. In 1859 Prince published his "Journal," in which he states that he considers himself perfect and incapable of further improvement.

AGAPETÆ (Gr. ἀγαπηταί, beloved), in the early church, virgins and widows who, from pious motives, devoted their time to waiting upon ecclesiastics. Men holding the same relations to societies of women were called agapeti. For some time the relation was maintained pure and blameless; but it resulted in immorality, and was condemned and prohibited by several councils.

AGARD, Arthur, an English antiquary, born about 1540, died in London, Aug. 22, 1615. He held the office of deputy chamberlain 45 years. His name headed the list of members of the society of antiquaries formed by Archbishop Parker in 1572, and six important papers by him are included in Hearne's collection (Oxford, 1720). They treat largely of the early organization and manners of England. Agard bequeathed all his manuscripts to his friend Robert Cotton.

AGARDH, J. Karl Adolf, a Swedish naturalist, born at Bastad, Jan. 22, 1785, died in Carlstad, Jan. 28, 1859. In 1807 he was appointed teacher of mathematics in the university of Lund, and in 1812 professor of botany and natural sciences. He was admitted to holy orders in 1816, and was made bishop of Carlstad in 1834. He devoted considerable attention to political economy, and also wrote on theological and other subjects, but his reputation chiefly rests on his botanical works, especially *Systema, Species*, and *Icones Algarum* (1824, 1820-'28, and 1828-'35). The greatest part of his "Manual of Botany" (2 vols., Malmöe, 1829-'32) has been translated into German. **II. Jacob Georg**, son of the preceding, born at Lund in 1813, has been since 1854 professor of botany there. His principal work, *Species, Genera et Ordines Algarum* (4 vols., Lund, 1848-'63), is regarded as a standard authority.

AGARIC, Mineral, a marly earth, akin in color and texture to the vegetable of that name.

AGARICUS, the genus of fungi which comprises the common mushroom, *A. campestris* (see MUSHROOM), many of the toadstools, and a few poisonous species. The genus is distinguished by the radiating gills bearing the spores on the under side of the pileus or cap. Several hundred species have been described, most of them edible, some easily cultivated.—The name is often applied to the more solid portions of fungi of other families, as the birch agaric, *polyporus betulinus*, which is cut in strips and used to sharpen delicate instruments. From *P. formentarius* amadou is prepared by cutting the fungus into slices and steeping in a solution of saltpetre; it then makes excellent tinder. In medicine several species of *polypo-*

rus were formerly much used as cathartics under the name of agaric, but have given place to better remedies. The powdered pileus of *P. igniarius* is mixed with snuff by the Ostiaks of the river Obi to improve its narcotic properties. Both in the pulverized form and when beaten into thin sheets it is used as lint. When old the polypori often attain a diameter of two or three feet, and become quite hard and woody. An approximate analysis shows much resinous matter and a peculiar substance called fungine (see FUNGI), but less nitrogenous matter than is usual in this order of vegetables. As they grow on the stems of many trees valued for their timber, and as their presence indicates decay, which they hasten by penetrating the wood with their mycelium, the portion answering to roots, it is desirable, in order to stop the progress of decay, to remove the external fungus and destroy the mycelium by a strong solution of sulphate of copper.

AGASIAS, a Greek sculptor of Ephesus, who is presumed to have lived at or before the time of Alexander the Great. The statue now at Rome, known as the "Borghese Gladiator," is his work. It represents a warrior on foot contending with a mounted combatant.

AGASSIZ, Louis John Rudolph, an American naturalist, of French descent, born in Motiers, canton of Fribourg, Switzerland, on the lake of Morat, May 28, 1807. His family was among the Huguenots who were driven from France by the revocation of the edict of Nantes, and took refuge in the Pays de Vaud. For six generations the lineal ancestors of Agassiz have been clergymen. His father was pastor of St. Imier, a Protestant parish in the ancient bishopric of Basel, and removed to Motiers on account of the severity of the climate at the former place; his mother was Mlle. Rose Mayor, the daughter of a physician in the canton of Vaud. She superintended the education of her son Louis until he reached the age of 11, when he was sent to the gymnasium of Bienne, a small town in the canton of Bern. In the mean time his father had removed from Motiers to the little town of Orbe, at the foot of the Jura. Here, during the vacations, the student's attention was drawn to the natural sciences, under the influence of a young clergyman named Fivaz. His studies were first directed to plants. Having studied four years at Bienne, Louis entered the college of Lausanne, where he passed two years, and then went to Zürich in 1824, where he remained two years in the medical school. He continued his medical studies at the university of Heidelberg, devoting himself chiefly to anatomy and physiology under Tiedemann, zoölogy under Leuckart, and botany under Bischoff. In the autumn of 1827 he entered the university of Munich, which had recently been reorganized. Among the eminent men assembled there Agassiz formed intimate friendships. He studied the organization of plants and their geographical distribution with Martius; he lived in the

house of Döllinger, with whom he studied the embryonic development of animals; he was intimate with Wagler; with Oken he discussed the principles of classification; with Fuchs he studied mineralogy; and for four successive years he attended all the lectures of Schelling on philosophy. He was the leading spirit in a select circle of young men who met to discuss scientific subjects. This society was called the little academy, and so interesting were the lectures and discussions that the professors were glad to take part in them. When Dom Pedro of Brazil married an Austrian princess, the Austrian and Bavarian governments seized the opportunity of sending to that country a scientific exploring expedition. The naturalists of the expedition were Martius, Spix, Natterer, and Pohl. Agassiz, still a student, had already published a few special papers. On the return of the scientific corps, Martius occupied himself with the publication of his great work on Brazil. The zoölogical portion was intrusted to Spix, but he had not completed it at the time of his death. Martius immediately selected young Agassiz to elaborate the ichthyological department, upon which very little had been done, and the manner in which he accomplished the task placed him at once in the foremost rank of naturalists. These studies and labors diverted him from the profession of medicine, to which he had been destined by his parents. The allowance he had hitherto received from his father, on which, moderate as it was, he had not only subsisted, but had employed a distinguished young artist, Dinkel, was now withdrawn. Agassiz then applied to Cotta, the publisher, who, struck by the value of the materials Agassiz had collected for a "Natural History of the Fresh-water Fishes of Europe," and no doubt impressed with the genius of the young naturalist, enabled him by a timely supply of funds to complete the work. This was his second great undertaking. Meantime he presented himself as a candidate for the degree of doctor of philosophy, which he took at Erlangen, after passing a very severe examination with distinction. In the same year he took at Munich the degree of doctor of medicine, on which occasion he maintained the superiority of woman in a Latin dissertation upon the thesis, *Femina humana superior mari*. The great work on the fresh-water fishes was advancing. After the double examination for degrees, Agassiz visited Vienna, where he prosecuted his studies in the museum, and devoted himself especially to the study of the fishes of the Danube. In that city he became acquainted with the leading naturalists, and particularly Fitzinger. While studying living fishes, his attention was drawn to the fossil species found in the fresh-water deposits of Oeningen and Glarus in Switzerland, and of Solenhofen in Bavaria. Immediately after the completion of the work on the fishes of Brazil, he commenced his researches upon the fossil fishes, and devoted seven years to the study be-

fore beginning the publication. This was continued through ten years, and was brought to a close in 1844. In the course of his preparation for this work, Agassiz visited the principal museums of Europe, accompanied by a skilful artist; and so great was the interest felt universally in these researches, and the confidence which the author inspired, that he was allowed to take with him for examination and comparison the most valuable specimens of more than 80 public and private museums, some of which he was permitted to retain from five to ten years. He was enabled to visit Paris and to prosecute his researches in the collections of that capital, by a most disinterested act on the part of a clergyman and friend of his father, Mr. Christinat, who at a later period visited Agassiz in America, and passed some years in his house. This gentleman had just come into possession of a small sum of money, which he offered in aid of his young friend's pursuits. Agassiz at once became acquainted with Humboldt, who was then residing in Paris, and with Cuvier, the eminent naturalist, who had just commenced his work on fishes. The drawings of Agassiz so delighted Cuvier, that he offered to relinquish to the young man all the materials he had himself collected; and from that time to his death he cherished a warm friendship for the Swiss naturalist, and received him in his family on the most intimate terms. In his investigations of the fresh-water fishes, the rivers and lakes of Europe were thoroughly explored by Agassiz, in order to compare those of the different water basins, especially the Rhine, the Rhône, and the Danube, with their tributaries. These investigations had mostly been made while he was still a student in Heidelberg and Munich, during the vacations, when he travelled on foot over the whole of southern Germany and Switzerland. Some time after the death of Cuvier, 1832, Agassiz returned to Switzerland, on the invitation of citizens of Neuchâtel, where preparations were making to reorganize the college. He received the appointment of professor of natural history in that establishment, and began preparations for the publication of the work on which he had been occupied so long. He also extended his researches to other departments of zoölogy. In 1833 he was enabled by the liberality of Humboldt, who had been his devoted friend since the commencement of their acquaintance in Paris, to begin the publication of the great work on the fossil fishes. This is in 5 volumes, with a folio atlas containing about 400 plates. About 1,000 species are described and figured in the natural size, with the colors of their beds, and there are short indications of about 700 more. The discovery and description of so many new species led to the recognition of new types, and an entirely new classification, based chiefly on the characters of importance in the fossils. The great generalizations to which these researches led have stood the test of time, and have been strengthened and ex-

tended by later investigations. The geological results of these researches were remarkable. The relative ages of the formations in which the fossil fishes were found were more clearly established by comparisons of their structures. Moreover, the fossil species differ from those now living, and differ in different stages of the same formation, as well as in different formations, leading to the conclusion that our globe has been peopled by a series of creative acts; and, as peculiar species occur in certain regions and not elsewhere, that these creations were not only successive but local, each having assigned to it a natural limit—man alone, and the animals associated with him, forming the exceptions to this last general law. From this general survey Agassiz drew several very important conclusions respecting the relation of the Creator to the universe. The existence of a superior intelligence, whose power alone could establish and sustain such an order of things, he considers to have been established by rigid demonstration, and on a truly scientific foundation. He believes that species do not insensibly pass into each other, but each has its appointed period, and is not connected, except in the order of time, with its predecessor. "An invisible thread, in all ages, runs through this immense diversity, exhibiting as a general result the fact that there is a continual progress in development, ending in man, the four classes of vertebrates presenting the intermediate steps, and the invertebrates the constant accessory accompaniment. Have we not here the manifestations of a mind as powerful as prolific? the acts of an intelligence as sublime as provident? the marks of goodness as infinite as wise? the most palpable demonstration of the existence of a personal God, author of all things, ruler of the universe, and dispenser of all good? This, at least, is what I read in the works of creation." Such is the tone of the closing part of the chapter on classification. Prof. Agassiz visited England several times, and was everywhere received with respect and enthusiasm. The universities of Edinburgh and Dublin conferred on him the degree of LL.D., and the corporations enrolled him among their citizens. He was the guest of Sir Robert Peel, and Lord Egerton, afterward Lord Ellesmere, and Sir Philip Egerton, honored him with a lifelong friendship. Of the eminent naturalists, Buckland, Owen, and Sir Roderick Murchison should be enumerated as among his friends. In 1834 his "Prodromus of the Echinoderms" appeared, which was soon followed by his monographs on that class of animals, in the preparation of which he was aided by Prof. Valentin and Mr. Desor. During this period he continued to collect materials for his "History of the Fresh-water Fishes." He formed a lithographic establishment at Neuchâtel, where the plates for the atlas of this work were executed, and the prints struck off under his own eye. The great expense, however, exhausted his pecu-

niary resources, and he not only found it impossible to continue it on the original plan, but it entailed upon him a heavy debt, which cost him the labors of many subsequent years to pay off. In the elaboration of some portions of the subject he was assisted by Karl Vogt, a Swiss naturalist, distinguished for his zeal and attainments in zoölogy. The publication of the "Fresh-water Fishes," in 1839-'40, was followed by the *Nomenclator Zoologicus*, containing an enumeration of all the genera in the animal kingdom, with the etymology of their names, the names of those who first proposed them, the date of their publications, &c. This work was founded upon registers, in which Agassiz entered the names of the animals as they occurred in his studies. They were then methodically arranged, the nomenclature of each class being submitted to the revision of naturalists distinguished for their investigations in each special branch. This was accompanied by another extensive and important work, the *Bibliotheca Zoologie et Geologie*, containing a list of the authors mentioned in the former, with notices of their writings. This work, published at the expense of the Ray society in England, has appeared since the author's residence in the United States, with emendations and additions by H. Strickland and Sir W. Jardine, in 4 large octavo volumes.—From 1836 to 1845 Agassiz spent his summer vacations among the Alps, chiefly engaged in the study of the glaciers and the geological phenomena they produce. The indications of their greater extension in a former period, and the traces they have left upon the surface of the earth, were carefully followed through the countries adjoining Switzerland, as well as England, Scotland, and Ireland. Before him, De Saussure, Venetz, Charpentier, and others, had written upon the glaciers, and the distribution of boulders over the valley of Switzerland. De Saussure's theory of their distribution referred it to the action of water. The idea of glacial agency in transporting boulders appears to have originated among the chamois hunters, who had noticed the fact that every year huge masses of rock were moved by glaciers from their original position. This idea was adopted by Venetz, and extended by Charpentier, who explained the distribution of the boulders throughout the valley of Switzerland, and on the slopes of the Jura, by the extension of glaciers beyond their present limits in a former period. In 1836 Agassiz visited Charpentier, and accompanied him to the glacier of the Diablerets, where he saw the actual transportation of the boulders by the glacier, and the rounding and polishing of the rocks at its sides. These observations removed his former doubts. It was obvious that such an accumulation of ice as would extend the glaciers from the Alps to the Jura, covering the valley of Switzerland to the depth of more than 2,500 feet, would require a depression of temperature which must have

been widely felt, producing similar phenomena over other portions of the earth's surface; that the north of Europe must have been at the same time covered with a similar sheet of ice. Agassiz first announced his glacial theory in a discourse delivered before the Helvetic society in 1837; but in order to investigate the facts more thoroughly, he first visited most of the Alpine glaciers, and then established his headquarters on the glacier of the Aar, where for eight consecutive summers he continued the researches which formed so large a part of his scientific labors in Europe. These researches are embodied in two works. The first, entitled *Études sur les glaciers*, published in 1840, with plates, contains a description of the glacial phenomena and a statement of the author's views of their former extent. The second, published at Paris in 1847, under the title of *Système glaciaire*, contains an account of the investigations made during his last five visits, 1841-'45, upon the mode of progress of the glaciers, and is accompanied by plates and a topographical chart. An excellent and graphic account of these visits and researches is given in a little work by his companion, Mr. Edward Desor, *Excursions et séjours de M. Agassiz et de ses compagnons de voyage dans les glaciers et les hautes régions des Alpes*. Since his residence in the United States, Professor Agassiz has occupied himself with investigations of the distribution of the boulders and the smooth surface of beds of rock over the North American continent, which he also attributes to the action of glaciers, extending from the north. The results of these investigations are chiefly recorded in the volume containing an account of an excursion to Lake Superior.—From 1846 the biography of Mr. Agassiz belongs to the scientific history of the United States. In the autumn of that year he arrived in Boston, from Paris. The object of his visit was, in the first place, to make himself familiar with the natural history and geology of this country, in fulfilment of a mission suggested to the king of Prussia by Alexander von Humboldt, and in the second place to meet an invitation from Mr. John Amory Lowell to deliver a course of lectures in Boston. Eighteen months or two years had been allotted to the first task, and ample means were provided by the Prussian government for that purpose. Soon after his arrival in Boston Prof. Agassiz delivered his first course of Lowell lectures, consisting of a general review of the animal kingdom. These lectures were listened to by audiences of 1,500 to 2,000 hearers, embracing all that was most cultivated in science and letters in the society of Boston and the vicinity. Immediately afterward, by special request, he delivered another course upon the glaciers and the phenomena connected with their former greater extension. Having completed these labors, he visited New York, Philadelphia, and Charleston, to compare the animals of the northern shores with those of the more southern latitudes of this

continent. On his return to the north early in the summer of 1847, he met with Prof. A. D. Bache, superintendent of the United States coast survey. Mr. Bache invited him to avail himself of the facilities presented by the operations of the coast survey for the further prosecution of his researches. The offer was so liberal and of such importance in a scientific point of view, that Agassiz could hardly credit his good fortune; and upon being assured that he might without difficulty visit at will every point of the coast in the well-equipped coast survey vessels, he exclaimed that this would decide him to remain to the end of his days in the United States. He spent part of the summer of 1847 on board the Bibb, commanded by Capt. C. H. Davis, on the coast of Nantucket and Martha's Vineyard. The immediate result of this, and a second cruise along the same coast, was several papers upon the medusæ of Massachusetts, and upon a coral found near Holmes's Hole. In the same summer he visited, in company with Mr. J. A. Lowell, Niagara falls and the White Mountains. During the next three winters he delivered courses of lectures before the Lowell institute upon comparative embryology and the successive development of the animal kingdom. At the close of 1847 Mr. Abbot Lawrence founded the scientific school in Cambridge, and a professorship of zoölogy and geology was offered Mr. Agassiz, which he accepted, after having obtained from his government an honorable discharge. He entered upon his duties in Cambridge in the spring of 1848, and at the close of the academic year started with 12 of his pupils upon a scientific exploration of the shores of Lake Superior. The results of this journey are contained in the volume entitled "Lake Superior," the narrative part of which was written by Mr. J. Eliot Cabot, together with the reports of the lectures the professor delivered at the close of each day. Dr. J. Le Conte contributed the account of the coleoptera. In 1848, in conjunction with Dr. A. A. Gould, he published "Principles of Zoölogy," for the use of schools and colleges. From that period Prof. Agassiz has devoted his time alternately to teaching and making original investigations. Besides his university lectures he has delivered in the winters courses of lectures in different parts of the country, while exploring its natural history. In these excursions he has been accompanied by assistants, and the collections he has made are the most complete extant, embracing the whole range of the animal kingdom. In this manner he has traversed the country from Lake Superior to the gulf of Mexico, and from the Atlantic coast to the valley of the Mississippi, delivering courses of lectures in Savannah, Mobile, New Orleans, St. Louis, Cincinnati, and many other places, besides those already mentioned. In 1850 he spent the winter upon the reef of Florida, in the service of the coast survey, ascertaining the mode of growth and the direction of the in-

crease of the reef. In the following summer he explored the state of New York with Prof. James Hall, and afterward he visited again the most important localities with his pupils. In 1852 he accepted a professorship of comparative anatomy in the medical college of Charleston, S. C., which he retained for two successive winters, making at the same time a thorough study of the marine animals of that coast, and extending his excursions to Georgia and North Carolina; but finding the climate injurious to his constitution, he resigned the situation, and returned to reside permanently at the north. In 1868 he was appointed a non-resident professor in Cornell university, at Ithaca, N. Y.—Since 1855 his attention has been largely devoted to the arrangement of the materials collected in these explorations. To form an adequate idea of the extent of his collections, it ought to be known that besides his own efforts, and the assistance he has derived from the young men accompanying him everywhere, he has been much assisted by the friends he has made in every state during his excursions. The collections embrace also the western coast; he has regularly received large contributions from California through his brother-in-law, Mr. Thomas G. Cary, Jr., who has collected for him extensively there. The results of all these explorations and investigations are now publishing in the work entitled "Contributions to the Natural History of the United States." Four volumes out of ten of this extensive work have already passed through the press. The subscription list extends to the unexampled number of 2,500 names, in all parts of the United States; a magnificent support of a purely scientific undertaking, executed on a grand and expensive scale, and an appreciation of the labors of a great original investigator, such as has never before been exhibited to the world.—Prof. Agassiz's eminence as a scientific man was early recognized in Europe. In 1836 he was elected into the academy of sciences in Paris and the royal society of London, and soon after received similar honors from all the other great learned societies in Europe and America. He has received from the academy of sciences in Paris the Monthyon prize for experimental physiology, and the Cuvier prize; the Wollaston medal from the geological society of London; and the medal of merit from the king of Prussia. He has been a copious contributor to the leading scientific journals of Europe and America, and has made numerous communications to the learned societies of which he is an active member. In the United States, his activity has been most beneficial in the American scientific association, the American academy of arts and sciences, and the Boston natural history society, the proceedings and transactions of all of which have been constantly enriched from his boundless resources. He is a man of great physical vigor, but his constant labors have more than once been followed by imperative calls for rest. The vacations of a naturalist

are often more productive than the term time of most men, and science lost nothing when in the winter of 1865 he accepted the liberal offer of a Boston merchant, who undertook to provide for the entire expenses of six assistants and the transportation of specimens, if the vacation journey should be to Brazil. The labors of his youth on the great Brazilian collections of Spix had created in him a strong desire to study the fauna of this region, and on the 1st of April, 1865, he started on an expedition whose results are seen in the immense collections now stored in the Cambridge museum. At Rio de Janeiro he was cordially welcomed by the emperor and received all possible assistance from the Brazilian government, a river steamer being assigned for his especial use. After some time devoted to excursions in the environs, during which he settled the disputed question of the existence of drift phenomena in the southern hemisphere, he sailed for Pará, and thence ascended the Amazon to Tabatinga on the Peruvian frontier. Here the party divided, and while Agassiz went down the river again, stopping at Ega or Teffé, Manaus, and other points, to pursue his researches into the ichthyology of the region, some of his assistants continued the exploration of the upper waters. Returning to Rio after a year's absence, he made some interesting excursions among the Organ mountains, and in July, 1866, sailed for the United States. The narrative of this journey, written mainly by Mrs. Agassiz, was published in 1868; and one of his assistants two years later published the geological report of the survey. Since his return from Brazil Agassiz has made a short excursion to the Rocky mountains. His arduous labors in extending the museum of comparative zoölogy at Cambridge have again shown him the need of rest; and early in December, 1871, he started on a voyage around Cape Horn in the coast survey steamer *Hassler*, in company with several other men of science. The results of this voyage, undertaken for deep-sea dredging, have already proved to be of great importance in the study of oceanic fauna.—The influence of Agassiz upon the scientific development of the United States has been profound and far-reaching. He has called into energetic action the minds of a large body of young men of science, who are laboring in every field of investigation with the enthusiasm he has inspired in the methods he has taught, and whose faithful study has contributed largely to the works since published by the master.

AGATE (from the river *Achates*, now *Dirillo*, in Sicily, near which it was found), one of the modifications in which silica presents itself nearly in a state of purity, deposited, not crystalline, but massive and, slightly transparent. Agate, onyx, chalcedony, carnelian, sard, chrysopease, and many others are but varieties, differing only in external form and appearance from each other, of the one family, quartz. When

other ingredients, as alumina or oxide of iron, are found associated with the silica, it appears that their presence is never in any fixed proportion, and is therefore regarded as accidental. Agates are distinguished from the other varieties by the veins of different shades of color which traverse the stone in parallel, concentric layers, often so thin as to number 50 or more in an inch. When these stripes alternated, an opaque band with one transparent, the stone was called onyx, from a fancied resemblance to the alternating lines upon the finger nail, from the Greek *ὄνυξ*. The modern distinction between agate and onyx refers to the direction in which the stone may be cut; when vertical to the stratification, so as to show stripes or bands, it is called agate; and the same stone, if cut parallel with the strata, is termed onyx, and forms the material of the true cameo. The veins of the agate are no doubt produced by successive deposition of one layer of silicious matter upon another, introduced in a sublimated or soluble form into the cavities of the rocks, where the agates are now found. These rocks are mostly amygdaloids, the cavities of which are filled by a variety of minerals. As the rock disintegrates, or wears away by the action of atmospheric agencies, the hard nodules of agate drop out, and are then found upon the surface, or, as is frequently the case, strewn along a sea beach or in the beds of mountain streams. Externally they are rough, and exhibit no appearance of their beautiful veined structure, which is exposed on breaking them, and still more perfectly after polishing. The largest nodules seldom exceed a foot in diameter. Various processes are adopted for increasing the lustre and heightening or darkening the colors of agates. They are boiled in oil, or kept in warm honey, and then dropped into sulphuric acid. The layers being unequally porous, the absorbed carbonaceous matter becomes charred and blackened by the acid, and the white stripes, impenetrable to the oil, appear clearer and brighter by the contrast. Agates are thus made to assume the onyx character, which is desired by the lapidary for the production of cameos and intaglios, in imitation of the antique sculptured gems. In these the figures, whether in relief or intaglio, are of a different color from the ground. Digestion for a few weeks in hydrochloric acid, kept at a moderate heat, gives a beautiful clear yellow color to the streaks that were before a dirty brown. Stones of a reddish hue are greatly improved in brilliancy of color by first thoroughly drying them for weeks in ovens, then dipping in sulphuric acid, heating to full red heat, and afterward slowly cooling. The changes that take place in both these processes are upon the oxide of iron, which is the coloring matter. They may suggest other modes of producing other analogous effects.—Though the varieties of agate are mostly very common minerals in this country, as well as in the old world, those localities only are of interest which have

long been famous for their production, and which still furnish all the agates required by commerce. The value of the stones depends upon the work put upon them, which from their extreme hardness is very laborious, and in the sculptured gems requires the greatest patience and skill. Such operations are not yet introduced into the United States, and the agates found everywhere accompanying the trap rocks meet no demand except from specimen hunters. The principal works for cutting and polishing agates are at Oberstein, a small town not far from Mayence, in south Germany. Here are numerous water mills running the coarse stones for grinding down the surface of the agates, and the wheels of soft wood on which they are polished with the powder of tripoli, found in the neighborhood. They are made into trinkets, cups, seals, rings, handles for swords, knives and forks, and small mortars for grinding very hard substances used by chemists.—Moss agate, or Mocha stone, is grayish white or brownish yellow, with peculiar markings of dark metallic oxide, assuming varied fanciful forms. Landscapes, trees, mosses, and animals have been traced in the lines formed by the arborescent deposit of the foreign mineral, chiefly oxides of iron or manganese. The numerous silicious springs of our western territory, at no distant date, have produced these, now generally known as Rocky mountain agates, some of which are of extraordinary beauty and wonderful resemblance, rivalling those in the museums of Europe that for ages have excited the admiration of the curious. Many of the latter, however, are such remarkable likenesses, that they must be regarded as exceedingly ingenious works of art. One in the British museum presents a likeness of the poet Chaucer; another in the church of St. Mark in Venice represents a king's head with a diadem. De Boot, in his treatise *De Gemmis*, describes one which represents the figure of a bishop with his mitre, placed in the centre of a perfect circle. By turning the stone a little another figure appears, and turned still further the figures of a man and woman are seen. Pliny mentions one belonging to Pyrrhus, in which were pictured the nine muses, with their proper attributes, and Apollo in the middle of the figure playing on the harp. While nature has formed remarkable coincidences of resemblance, yet the credulous have been imposed upon by stone engravers, from the 15th century to our own day, by engraving a device on a soft chalcedony, with a uniform depth of cutting, and staining the stone as before described; then grinding off the surface to the depth of their cutting, leaving the stone smooth, but showing stain where the engraved lines had been. The same means were used to heighten natural marks, as well as the more legitimate mode of curving or waving the surface, so as to erase or bring out desired features.—Agate frequently occurs as a geode, or hollow nodule, explained by the theory of gas

entering a silicious solution. Change of temperature and pressure account for the crystalline interior, and the various strata are evidently aggregations, usually concentric. The veins of color are sometimes polygonal, when, from resemblance to the angles of a fortress, it is called fortification agate.

AGATHA, Saint, a Christian martyr of Palermo. Her beauty attracting the attention of Quintianus, the pagan governor of Sicily, he made overtures to her. Enraged at their rejection, he subjected her to the most cruel tortures, and she died in prison, Feb. 5, 251.

AGATHARCHIDES, or Agatharchus, a Greek geographical writer, a native of Cnidus in Asia Minor, who flourished about 130 B. C., and was guardian to one of the kings of Egypt during his minority. Of his numerous works, fragments of a description of the Erythrean sea alone remain.

AGATHARCHUS, an Athenian artist of the early part of the 5th century B. C., said to have invented scene painting, and to have painted a scene for Æschylus. Scene painting was, however, not generally used until the time of Sophocles.

AGATHIAS, a Byzantine writer of the 6th century, surnamed Scholasticus on account of his extensive legal knowledge, born in Myrina, in Asia Minor. He received his early education at Alexandria, and in 554 went to Constantinople, where he practised as an advocate and won renown as a poet and historian. Of his writings, about 90 poems are extant, as well as a history of the government of Justinian, which was intended for a continuation of Procopius. It was first published in 1594, and afterward with Niebahr's amendments in 1828.

AGATHOCLES, a Syracusan adventurer and military despot, died in 289 B. C. He was the son of a potter in the Sicilian town of Therme, an exile from southern Italy, and in early life worked at his father's trade, then became a leader of banditti, and afterward a soldier under Damas, a prominent Syracusan, with whom he subsequently served as a chiliarch or commander of 1,000 men, in the war with Agrigentum. On the death of Damas Agathocles married his widow, and thereby became one of the wealthiest citizens of Syracuse. He obtained an ascendancy in the democratic party, was twice driven into exile, but returned, and after terrible bloodshed became autocrat of Syracuse in 317 B. C. Debts were abolished, and the property of the rich was confiscated and distributed among the people. He aimed to drive the Carthaginians out of Sicily, and annex the whole island to the state of Syracuse; but he was defeated by Hamilcar, the Carthaginian governor, near Himera, and shut up in Syracuse on the land side. The sea being open to him, he carried the war into Africa in 310, burnt his ships on landing, and obtained many successes over the Carthaginian troops and cities. The subject allies of Syracuse in Sicily revolted, headed by the

powerful city of Agrigentum, and placed themselves under command of Dinocrates, a Syracusan Greek. Agathocles hurried home, but achieved nothing decisive in Sicily, and returned to Africa, where he found his troops mutinous from want of pay. His eloquence saved him. Defeated by the Carthaginians, he and his sons fled to the coast, leaving the army to look out for itself (307). The sons were caught and massacred by the troops, who then made terms with the Carthaginians. Agathocles escaped to Sicily, made peace with the Carthaginians, turned his energies against the revolters, defeated them, butchered thousands after they had laid down their arms on promise of amnesty, and took Dinocrates into his service. He next set on foot an expedition against the Bruttii in Italy, laid the Lipari islands under contribution, made himself master of Crotona on the peninsula, and had advanced far toward raising Sicily to a great naval power when he died.

AGATHON, a tragic poet of Athens, a friend of Euripides, born about 447 B. C., died about 400. He won his first dramatic triumph in 416. Aristophanes ridicules his affectations, and brings him on the stage in a woman's dress. Plato and Aristotle speak well of his talents, but the latter remarks the mild, humane spirit of his tragedies as a sign that the vigor of the ancient drama was departing. He went with Euripides to the Macedonian court in 407, and fixed his abode in the palace of King Archelaus. The dinner which Agathon gave to celebrate his dramatic victory was made by Plato the groundwork of his Symposium. Of his writings a few fragments only are extant. Wieland made Agathon the hero of a philosophical novel.

AGAVE, a genus of plants of the order *amaryllidaceæ*, known as American aloes. The plant produces a circle of stiff, erect, fleshy leaves, often 7 to 10 inches long and 5 to 7 inches thick at the base, growing on the top of a short, woody trunk, bearing flowers in a long, terminal, woody spire. There are several species, but only one merits especial notice. The *agave Americana*, American aloe (called *maguey* in South America and *mescal* in Mexico), has a short cylindrical stem, terminating in a circular cluster of hard, fleshy, spiny, sharp-pointed, bluish-green leaves, each of which lives for many years, so that but few have withered when the plant has arrived at its maturity. It is a popular error that this only occurs at the expiration of a hundred years, when the tree flowers, and again lies dormant, so far as its efflorescence is concerned, for another century. The American aloe varies in the period of its coming to maturity, according to the region in which it grows, from 10 to 70 years. In hot climates, otherwise favorable to its rapid development, it grows quickly, and early attains its perfect state. In colder countries, where it is cultivated as an exotic, it often requires the full period popularly

assigned to it before it has attained its maturity. So soon as it does so, it sends forth a stem 40 feet in height, which puts out numerous branches, forming a cylindrical pyramid of

Agave (American Aloe).

perfect symmetry, each crowned with a cluster of greenish-yellow flowers, which continue in perfect bloom for several months. But at whatever period of the plant's existence this occurs, it is never repeated; as soon as the flowers fall, the plant withers and dies. The natural habitat of the American aloe is the whole inter-tropical region of America, in which it flourishes from the sandy plains on the level of the sea to the table lands of the mountains, at a height of 9,000 to 10,000 feet. In England, the United States, and France, it is a tender greenhouse plant; but in Spain, Italy, Sicily, and the Barbary states, it is perfectly naturalized.—The American aloe is applied to many uses. From its sap, drawn from incisions in its stem, is made *pulque*, a fermented liquor highly esteemed by the Mexicans; and from that, again, is distilled an ardent and not disagreeable, although singularly deleterious spirit, known as *vino mezal*. A coarse sort of thread is made from the fibres of the leaves, known as the pita flax. The dried flower stems constitute a thatch which is perfectly impervious to the heaviest rain. From an extract of the leaves balls are manufactured which can be made to lather with water like soap; and from the centre of the stem, split longitudinally, a substitute is obtained for a hone or razor strop, which, owing to the particles of silica which form one of its constituents, has the property of speedily bringing steel to a fine edge.

AGDE (anc. *Agatha*), a city of southern France, department of Hérault, 95 m. W. of Marseilles; pop. in 1866, 9,586. It lies a short distance from the Mediterranean, on the left bank of the river Hérault, into which the Languedoc canal (canal du Midi) flows at this point.

The town is entirely built of basaltic lava from a neighboring mountain. It is the seat of considerable trade with Italy, Spain, and Africa. It was founded by the Greeks of Massilia (Marseilles) about 590 B. C. Alaric II., king of the Visigoths, held a council here in 506.

AGE, any particular period in the existence of organic beings, of collective humanity, of nations, or of the globe. The age of the world has been variously computed by geologists, but nothing positive is known of the real length of time allotted to each period, so strongly marked by changes in the structure of its crust, and in the forms of animals and plants which have left fossil traces of their existence. Many periods of inorganic change, and numerous mutations of animal and vegetable forms of life, are known to have occurred upon our globe before the slightest trace of man appears upon its crust; and hence it is inferred that human life, compared with the inferior forms of animal and vegetable life, is of comparatively recent date. The age of the world, then, has two distinct bearings, one referring to the origin and growth of the earth in its cosmological and geological existence, the other to the origin and history of man and of society upon its surface. Certain periods remarkable for some particular development in the life and progress of the race, or of a nation, are distinguished by particular names, such as the golden age, the silver age, the copper or the brazen age, and the iron age of heathen mythology, the Augustan age of the Roman empire, the Elizabethan age of English history, and the age of steam and iron in the progress of our own time. (See AGES.)—The life of man has been divided into seven ages by Shakespeare, and into four, five, six, seven, or eight, by men of science. Some make four distinct periods only, such as infancy, youth, maturity, decline; others follow more closely each physiological transition, and divide existence into infancy, childhood, boyhood or girlhood, adolescence, virility, maturity, decline, and old age or second childhood. The most natural divisions are those which distinguish the ascending, the culminating, and the declining periods of life. Each of these may be further subdivided according to physiological changes which mark the transitions from one period to another. Infancy, childhood, and boyhood or girlhood mark the first stage of ascending progress from birth to puberty; youth, adolescence, and manhood or womanhood mark the second stage of ascent in the growth and evolution of the powers of life; virility may be applied to the culminating period; and the descending stages of maturity and decline might well be subdivided into lesser and marked periods of transition, as are the two ascending stages. Infancy applies to the first two years of life, during which the first complete set of teeth is developed; childhood to the age, between 2 and 7 or 8, when the first teeth are shed, and a more complete set replaces them; boyhood and girlhood from 7 to 14 or 15, the average time of

puberty, which forms a marked transition, closing the first general phase of ascending progress. Here youth, properly defined, begins, and lasts until the age of 20 or 21, when the physical development becomes complete; the bones are firmly set in all their parts; the mind is also more or less developed; and the sexes have attained "majority" in social life. Adolescence is applied to the first period of adult life, from 21 to 28, and manhood to the riper period, from 28 to 35 or 36. The culminating period of physical and mental force combined is termed virility, and this may vary in different individuals, some waxing feebler soon, while others retain all their vigor from 36 to 48. The body then begins to lose its energy, and gradually declines through the descending periods of maturity and old age. The mind may still retain its power, and even acquire more knowledge and experience, but the body will not maintain so vigorous an exercise of thought and nervous action as in former years. The subdivisions of descending life are not so strongly marked, apparently, as those of the ascending phases; but in woman's life there is a critical period called "the change of life," which corresponds inversely to that of puberty. The capability of child-bearing begins with one and ends with the other. The "critical period," however, is not so fixed as that of puberty. With some it occurs at 40 or 42, while with others it extends exceptionally to 50, 55, or 60, and in some rare instances still later, the average being 45. This period of sterility is less marked and regular in man than in woman. Whatever be the length of the descending phase of life in different individuals, the ascending periods are nearly uniform in their average duration. The female sex is usually more precocious than the male, and women average longer lives than men; but that is probably because they are less exposed to accident and danger in the common course of things, for the extreme cases of old age recorded are more numerous in males than females.—Individuals become legally qualified for certain acts at given ages, and these vary in different countries according to the laws and institutions. A child under 10½ years of age is not amenable to the laws of England for serious offences; the parents are responsible for its actions in minor cases. Above that age the offender is responsible, when deemed competent to distinguish between right and wrong. The age of 14 is fixed by the civil law as the age of criminal responsibility; capital punishment, however, was inflicted for murder in 1629 on a boy of 8 years of age, who had most artfully concealed the body of his victim. The oath of allegiance may be taken after 12, and youths of either sex may choose a guardian at the age of 14; but no person under 21 can execute a valid will. The nubile age was fixed by the Roman law at 14 for males and 12 for females, and at these respective ages either sex may in England consent to marriage, with the approval of

guardians. By the *Code Napoléon*, the nubile age in France is 18 for males and 15 for females, with the approval of guardians; at 17 a person of either sex may be an executor or an executrix; and at 16 a minor may devise one half of his property. In the United States either sex may choose a guardian at 14; the nubile age is 14 for males and 12 for females. The age of majority, which gives both sexes the free disposal of themselves and their property, and the enjoyment of all civil rights belonging to their sex and condition, is 21 in the United States, Great Britain, and modern European countries generally; but in ancient Rome minority continued till the age of 25.—Some philosophers believe that, under well devised rules of conduct and favorable external conditions, the natural period of human life might be extended to 100 years, in lieu of the "threescore years and ten" of the Bible; and M. Flourens, a French physiologist of high standing, has published a work in which he treats of "human longevity" as dependent upon human prudence mainly, and easily prolonged by care to the limit of 100 years. The ages of the patriarchs before the flood have been a subject of critical dispute. With the exception of Enoch, whom "God took" at the age of 365, they are all represented in the Bible to have lived seven or eight centuries. Methuselah's age was 969, which is the greatest on record. After the deluge life gradually grew shorter. Shem died at 600, Abraham at 175, Isaac at 180, Jacob at 147, Joseph at 110. Commentators who reject the literal interpretation of the statements concerning the earlier patriarchs suppose either that the name of each patriarch denotes a clan or family instead of an individual, or that the sacred biographies are allegorical. History shows that the natural term of life has varied little during some 4,000 years, and the proportion of extraordinary cases of longevity continues much the same at present as it was in former times. The average duration of existence is, however, quite another question; and this varies with the favorable or unfavorable habits of the people with regard to industry, morality, and civilized culture. Nor has latitude or longitude much to do with the duration of life, either with regard to average, or natural, or extraordinary periods; for in all latitudes and longitudes, where natural conditions are otherwise equally favorable, natural, exceptional, and average periods maintain respectively a similar ratio. The average duration of life in Europe, according to statistical calculations, lies somewhere between 26 and 33 years; the highest average occurs in countries where wealth, commerce, and civilization are most generally diffused; the lowest where poverty and ignorance and despotism prevail. These facts have been carefully observed in our times by life insurance companies, as the basis of commercial calculations. In England the rate of mortality is said to be 24 per cent. per

annum; while in Russia the returns of 1842 gave $3\frac{1}{2}$ per cent. for the mortality of the whole empire, and considerably more than this for certain provinces, including the basins of the Volga, the Dnieper, and the Don. The average duration of life is therefore higher in England than in Russia; but we might probably find as many cases of exceptional longevity in Russia as in England, if statistical returns were made with equal care in the two countries. Comparative longevity has not received as much attention as the averages of mortality and the mean duration of existence in civilized states, but numerous authentic records of individual cases may be found in every nation. Pliny gives some instances of longevity taken exclusively from the region between the Apennines and the Po, as found on the record of the census instituted by Vespasian; and within these narrow limits he enumerates 54 persons who had reached the age of 100 years; 14, the age of 110; 20, 125; 40, 130; 40, 135; and 30, 140 years. In the single town of Valcaium near Placentia, he mentions 6 persons of 110, 4 of 120, and 1 of 150 years of age. Among the ancient philosophers and men of note, not to mention women, we find some cases of comparative longevity. Sophocles is said to have lived 90 years; Zeno, 98; Democritus, 99; Pyrrho, 90; Diogenes, 90; Isocrates, 98; Gorgias and Hippocrates, upward of 100; and numerous other instances of comparative longevity are recorded of ancient Greece and Rome, as well as of modern times and nations. Dr. Van Oven gives 17 examples of age exceeding 150 years; and Mr. Bailey, in his records of longevity, gives a catalogue of 3,600 or 4,000 cases of old age, verging closely on 100 or exceeding it, and not a few of them reaching as high as 150 years. Many of these cases may be more or less satisfactorily authenticated, but there can be no doubt of the occasional prolongation of human life beyond the age of 100, even up to 170, and in at least one instance to 185, the age of Peter Czartan, a peasant of Hungary, who was born in 1539 and died in 1724. But these cases are always exceptional in comparison with the average duration of life, and therefore, as judicious writers have observed, "no fit exponents of the universal natural capacity for life in man." The average, which falls below the natural term, might certainly be raised by due attention to the laws of nature and the known requirements of healthy life in states and cities, families and individuals. The natural term of life differs to some extent, no doubt, in different persons, though not as the natural stature differs in different families; for all men attain to virility about 35 or 40, however slowly they decline into old age. To this extent we may regard the natural term of human development as normal or constant; but some maintain their vigor many years, and then decline most rapidly and die, while others decline slowly and enjoy a long evening of life. This view of the

fact might give some plausibility to the theory of continuing for all by artificial means that slow decline which nature, unassisted, manifests in some rare instances; but nothing being known of the causes of such exceptional longevity, nothing can be logically predicated of the possible results of any human scheme for lengthening the descending period of human life.—Little is known of the age of animals, especially the non-domesticated tribes. Some isolated facts, however, have been noted with regard to the age attained by certain birds, fishes, reptiles, elephants, &c. The East Indians believe that the elephant lives about 300 years, and instances are on record of the animals having been kept in captivity as long as 130 years, their age being unknown when they were first taken wild from the forest. Camels live from 40 to 50 years; horses average from 25 to 30, oxen about 20, sheep 8 or 9, and dogs from 12 to 14 years. As a general rule, the larger types of animals live longer than the smaller, in the vertebrated classes, quadrupeds, birds, reptiles, and fishes. Some kinds of birds attain to a great age; the swan has been known to live 100 years; and there are instances on record of the raven having exceeded that age. Birds of prey attain to great longevity; the eagle has survived a century. Parrots have been known to live 60, and as long as 80 years. The gallinaceous tribes live not so long. Pheasants and domestic poultry rarely exceed 12 or 15 years. Reptiles of some kinds live very long. A tortoise was placed in the garden of the archiepiscopal palace of Lambeth in 1633, during the life of Archbishop Laud, and lived till 1753, when it perished by accident. Nothing is known of the age of large serpents, such as the boa, but small batrachians, as the toad, are known to live about 15 years. Fishes, and animals that live in the water, attain in many instances to a great age. The carp has been known to live 200 years. Common river trout have been confined in a well 30 and even 50 years. A pike has been known to live in a pond 90 years; and Gesner relates that in 1497 an enormous pike was caught in a lake near Heilbronn, in Swabia, with a brass ring attached to it, recording that it was put into the lake in 1230. The pike must have lived, therefore, at least 267 years. The ring is still preserved at Mannheim. The age of the whale is known by the size and number of laminae of certain organs in the mouth, formed of a horny substance, commonly called whalebone. These laminae increase yearly, and if the mode of computation be correct, they indicate in certain cases that the animal attains to an age of 400 years. Little is known of the age attained by animals of the lower types, such as articulata, mollusca, and radiata. That of insects has received some attention, and it has been remarked that though the first period of life, passed in the grub or caterpillar state, extends to several months or even years, the great majority live but a few

days or weeks after the metamorphosis by which they attain to a more perfect form. The ephemera, when it leaves its grub-life in the water, and assumes a higher form and an aerial existence, lives but a few hours, and dies the very day on which it was born into its new life; whence its name, *ephemera*, passing in a day.—The age of the horse in his ascending phase of life is known chiefly by the growth and appearance of the teeth, and more especially of the incisors, commonly called nippers. In each jaw of the horse there are six of these nippers, broad, thin, and trenchant in the foal; while in the adult animal the crowns become flat, and marked in the centre with a hollow disk. The foal or milk teeth appear about 15 days after birth. At $2\frac{1}{2}$ years of age the middle pair drop, and are replaced by the corresponding pair of permanent teeth. At $3\frac{1}{2}$ years the two next, one on each side, are likewise replaced. At $4\frac{1}{2}$ years the two external nippers or excisors drop and make room for the corresponding pair of permanent teeth. All these permanent nippers are flattened on the crown or upper surface, and marked in the centre with a circular hollow pit; this pit is gradually effaced, as the tooth wears slowly down to a level with the bottom. By the degree of this detrition, or wearing of the teeth, the age of the animal is determined up to the 8th year, when the marks are generally quite effaced. The external pair of nippers, however, appearing a year or two after the intermediate pair, preserve their original form proportionately later. The age of a horse may still be determined for a few years, after the 8th year, by the appearance and comparative length of the canine teeth, or tusches; these, however, are sometimes wanting, particularly in the lower jaw, and in mares they are rarely developed at all. The tusches of the under jaw appear at the age of $3\frac{1}{2}$ years, those of the upper jaw at 4. They are sharp-pointed until the age of 6, and at 10 become blunt and long, because the gums begin about that time to recede from the roots of the teeth, leaving them naked and exposed. After this period there are no certain means of determining the age of a horse, but some conjecture may be made from the comparative size, bluntness, and discolored appearance of the tusches.—The age of horned cattle is more readily determined by the growth of the horns than by the growth, succession, and detrition of the teeth. But the horns of oxen, sheep, goats, and antelopes, being hollow and permanent, differ widely in form, structure, and manner of growth from those of the deer tribe. The deer kind shed their horns annually, and, with the single exception of the reindeer, the males alone have horns. At first they have them in the form of simple prickets, without any branches or antlers; but each succeeding year adds one or more branches, according to the species, up to a certain fixed period, beyond which the age of the animal can only be conjectured from the size of the

horns and the thickness of the burr or knob at their roots, which burr connects them with the skull. The prickets or first horns of the common stag fall during the 2d year of the animal's life, each one being replaced by one with a single antler, and thence called the fork. This falls during the 3d year, and is replaced by the 3d kind, which has commonly 3 or 4, and sometimes 5 branches. The 4th and following pair have a like number of branches, and the number of antlers goes on increasing in the same manner till the 8th year of the animal's life; after which they follow no fixed rule, but continue to increase in number, particularly near the summit of the horn, where they are sometimes grouped in the form of a coronet, and thence called "royal antlers." The fallow deer, the roebuck, and other species of this genus, present similar examples of development; the number of the antlers increasing in a fixed ratio up to a certain time, beyond which the age, as in the stag, can only be determined by the comparative size of the burr and that part of the shaft or horn from which the antlers grow. In the fallow deer, the prickets of the 2d year are replaced by horns bearing two antlers already indicating the palmated form which afterward distinguishes them from the antlers of other deer. This palm increases in breadth, and assumes an indented form on the superior and posterior borders, and the 4th pair of horns, shed in the 5th year of the animal's life, are replaced by others in which the palm is cloven or subdivided irregularly into distinct parts, assuming in old animals a great diversity and singularity of form. Finally, the horns begin to shrink in size, and are said to end in becoming simple prickets as in the 1st year. The horns of oxen, sheep, goats, and antelopes are hollow and permanent. They consist of a sheath of horn covering a bony core or process of the skull, and growing from the root, where an additional knob or ring is formed each year; and thus the number of these rings is a sure indication of the animal's age. The growth of the horns is not uniform throughout the year, but varies with the seasons. The increase takes place in the spring, and there is no further addition until the following year. In the cow kind, the horns appear to grow uniformly during the first 3 years, and up to that period they are smooth and without wrinkles; but after the age of 3 years, each succeeding year adds a ring to the root of the horn. The age is determined, therefore, in this species, by allowing 3 years for the smooth part of the horn, and 1 for each of the rings, where they exist. In sheep and goats the horns show their first knob or ring in the 2d year, whence the top or smooth part counts for only 1. These peculiarities have not been sufficiently observed in antelopes to give us a rule for determining the age of the animal by the growth and appearance of the horn.—Some plants and trees run their whole career in a year or two, as the families of annual and biennial plants,

while a few species of the larger growth of trees live centuries, and even tens of centuries. The oriental plane, the baobab, the chestnut tree, the great *sequoia* of California, and the deciduous cypress are said to furnish individual specimens, the age of which attains to several thousand years; as much, in fact, as 4,000 or 5,000 years or more. Yew trees are reported to flourish in certain cases after a life of 1,500 or 2,000 years. Adanson found trees of the baobab species in Africa which he computed to be 5,150 years of age; and the younger De Candolle reports the deciduous cypress of Chapultepec, in Mexico, to be still older. The baobab of Senegal, measuring 90 feet in girth, and the gigantic *draecena draco* at Orotava in Teneriffe, which Humboldt classes with the baobab, are supposed to be among the oldest inhabitants of the earth. The famous sweet chestnut trees on Mount Etna, one of which measures 160 feet in circumference, another 70, and another 64, are said to be as old as the baobabs just mentioned; and the oriental plane tree in the valley of Buynkere, near Constantinople, having a girth of 150 feet and an internal cavity 80 feet in circumference, is deemed as old as any other tree existing. The great *sequoia gigantea* of the Mariposa and Calaveras groves of California, measuring 90 feet in circumference, and attaining a height of over 300 feet, without doubt lives over 2,000 years. Eight olive trees are still to be seen on the mount of Olives, at Jerusalem, which historical documents prove to have existed before the Seljuk Turks took possession of that city, 800 years ago; and the yew trees at Fountain abbey, in Yorkshire, were reported to be old when the abbey was erected, in 1132. They are probably more than 1,000 years of age now; and the old yew tree formerly in Fotheringhill churchyard in Perthshire, and measuring 56½ feet in circumference, was believed to have existed more than 20 centuries. At Ankerwyke house, near Staines, is a celebrated yew tree, older than the meeting of the English barons at Runnymede, in June, 1215, the date of Magna Charta; and many other cases of extreme antiquity are well authenticated with regard to the trees of the yew species. The trunk of the Ankerwyke house yew tree measures 9 feet 3 inches in diameter at 3 feet from the ground, and its branches overshadow an area of 207 feet in circumference. Many oaks have been cut down in the New Forest which presented as many as 300 or 400 concentric rings, each of which denotes a year's growth; and oaks exist much larger in dimensions and of greater age, some exceeding probably 1,200 years. Dr. Plott mentions an oak felled at Norbury which measured 45 feet in circumference. The Broddington oak, in the vale of Gloucester, was 54 feet in girth, and Damory's oak in Dorsetshire 68 feet. The age of the latter was computed to be about 2,000 years. Wallace's oak at Ellersley, near Paisley, in Scotland, is believed to be more than 700 years

of age, and is still flourishing. At Trons, in the Grisons, a lime tree measuring 51 feet in girth, planted in 1284, was still existing in 1792, and was therefore known to be nearly 508 years of age; and in 1776 some famous cypresses called *cypresos de la sultana*, in the palace garden of Granada, were reputed to be 800 or 900 years old. An elm tree planted by Henry IV. was standing in the garden of the Luxembourg palace, in Paris, at the commencement of the French revolution, 1789; and others are known to be of more than a century's growth; but it is not well ascertained that they sometimes, as affirmed, attain to the age of 300 years. Bacon's elms, in Gray's Inn walk, London, planted in 1600, decayed prematurely in 1720; and the elms of the long walk at Windsor, planted early in the last century, though still fine trees, are evidently past their prime. The way in which the age of some of these trees has been computed is twofold: first, by comparison with other very old trees, the rate of growth of which was known; and secondly, by cutting out a portion of the trunk from the circumference to the centre, and counting the number of concentric rings that are visible. In exogenous trees, the woody cylinder of one year's growth is divided from the succeeding and preceding by a denser substance, which marks distinctly the lines of separation between each year. The first of these methods is sufficiently trustworthy to give an approximation to the truth, and the second would be still better if care were taken to avoid all cause of error; but Dr. Lindley states in his "Introduction to Botany," that, owing to the extreme inequality of thickness in the annual layers of wood on opposite sides of a stem or trunk, an examination made on the stunted or less developed side only might lead to a miscalculation of the age; the error thus induced being in some cases as much as 60 per cent. or more. There is no good reason to suppose, however, that such mistakes are common, or that the ages of celebrated specimens, authenticated as above, have been obtained by such miscalculations. The palm trees, and some tropical tribes of endogenous plants, are said to attain to an age of 100 or 200 years, and it has been supposed that certain Brazilian cocoanut palms may be as much as 600 or 700 years old; but the method of computing their age is hardly to be relied on. This consists in counting the number of rings externally visible upon their rind, between the base and the summit of the stem, or by comparing the oldest specimens, the age of which is unknown, with young trees, of a known age and like species; but no confidence can be placed in such a method. The date palm, which is best known to Europeans, does not attain to a very great age. The Arabs do not assign to it a longevity exceeding two or three centuries. The mode of growth seems to preclude even the possibility of attaining to a great age, compared with the exogenous class. (See ENDOGENS, and EXOGENS.)

AGEN (anc. *Aginnum*, or *Agennum*), the chief town of the department of Lot-et-Garonne, France, on the right bank of the Garonne, 73 m. S. E. of Bordeaux; pop. in 1866, 18,222. The old quarter of the town is composed chiefly of narrow streets. The houses in the modern quarter are built on the slope of a hill adorned with trees and vineyards. Agen has been the see of a bishop since 347. Among the distinguished natives of the town were Sulpicius Severus Lacépède, and the younger Scaliger, whose more eminent father Julius removed hither from Verona. The last representative of the troubadours, the poet Jasmin, was also a native and resident of Agen. It is famous for its prunes and its manufacture of serges.

AGENT, in law, a person appointed to perform an act for another. He may be either special or general, or may be appointed either expressly or impliedly. No form of appointment is required. An agent may be created either by deed, or by a simple letter, or by word of mouth. To execute legal instruments, the authority must be equal in value with the instrument to be executed; thus a power to sign and execute deeds must be created by a power under seal. Some persons are agents by the very nature of their business, such as attorneys, auctioneers, bailiffs, brokers, shipmasters, factors, and others. The agent may bind his principal by his acts. Such liability must necessarily be brought within the scope of his authority; thus, the captain of a ship could not bind his owners in the purchase of a piece of land. The agent entering into a contract on behalf of a principal whose name he discloses is protected from personal liability; but, if acting on behalf of a principal unknown, he is himself liable, unless the third party elect to proceed against the principal. A professional agent is bound to exercise due diligence, and to bring a fair degree of skill and knowledge to the discharge of the duties he undertakes. If he be an unprofessional agent, he is still bound to exercise the ordinary judgment of a prudent man in the conduct of his own affairs. The circumstance of his being a gratuitous agent does not alter the liability of the agent to the principal in this respect. The limits of an agent's powers must be determined by the nature of his instructions. If special, he is limited to their strict letter; if general, he must act for the best interest of his principal, and the usages of trade and commerce will have considerable weight in determining the propriety of his conduct. He is bound to give early notice of all occurrences affecting his principal's interests; he is bound to account for funds immediately on their receipt, and even for the usufruct of the same if retained or employed by him; he may not buy from nor sell to his principal, unless by express assent; and in some cases contracts for the benefit of a person acting in a fiduciary capacity are absolutely

void. The rights of an agent are to reimbursement of all charges and expenses which he may have incurred in the proper discharge of his duties, and not caused by his own carelessness or negligence. He is also entitled to remuneration of a reasonable character for his services; and lastly, he is entitled to indemnity against the consequences of all acts done by him on behalf of his principal within his powers, provided that such acts are not wrongful to third parties, in which case the agent is personally liable. For the more complete protection of his rights in these respects, he has a lien upon all property of his principal placed in his hands.—The position of third parties may be inferred from the foregoing. The agent may, in his dealings with third parties, bind his principal in all matters fairly within the scope and object of his employment. If he exceed his powers, the third party has no claim whatever on the principal; the claim which the third party may have on the agent must depend on the nature of the case, and in particular on the fact of his principal being disclosed. Public officers, whether acting within their powers or not, are not liable for contracts entered into as such public officers. For wrongful acts and injuries (not of a criminal character) committed by agents, such as trespasses under color of law, or accidents resulting from negligence, the principal may be made liable, provided that the agent's acts be incontestably within the line of his duty. But the perpetrator of a wrong not being entitled, by the policy of the law, to shield himself behind a principal, the agent is liable as well as the principal.

AGES, a term used to designate various epochs in the civilization of the human race. Hesiod mentions five, and Ovid four. The golden age, synchronous with the reign of Saturn, was a period of patriarchal simplicity, when the earth yielded its fruits spontaneously and spring was eternal; the silver age, governed by Jupiter, was a lawless time, in which the seasons were first divided, agriculture took its rise, and men began to hold property in land; the brazen age, or reign of Neptune, was an epoch of war and violence; in the heroic age (omitted by Ovid) the world began to aspire toward better things; and in the iron or Plutonian age, in which Hesiod believed himself to be living, justice and piety had disappeared from the earth. Fichte divided human history into five ages, of which he conceived that we were in the third; while Hegel and Comte reckoned three, placing us in the last.—European archaeologists have divided the prehistoric period into the age of stone, so called because men are supposed to have been at that time unacquainted with the use of metals, and to have made their rude implements of the chase and husbandry exclusively of stone; and the age of bronze, when a compound of copper and tin was employed. The recent discoveries among the remains of the

lake dwellings of Switzerland have afforded strong confirmation of this theory, and supported the further opinion that the men of stone and the men of bronze were entirely distinct races. To the bronze age succeeded the men of iron. The antiquity of these ages is a matter of conjecture.—The term MIDDLE AGES is applied to the period of several centuries separating the ancient and modern epochs of European history, considered by some as extending from the fall of the western empire in 476 to the discovery of America in 1492; but other nearly synchronous events have been fixed upon for the beginning and end of the period. Properly speaking, there is no middle age in oriental history, but Hallam applies that term, for the Greeks and their eastern neighbors, to the era of Mohammed.—The DARK AGES is a term applied in its widest sense to that period of intellectual depression in the history of Europe from the establishment of the barbarian supremacy in the 5th century to the revival of learning about the beginning of the 15th, thus nearly corresponding in extent with the middle ages. The last of the ancient authors was Boethius, after whose death, about 524, the decline of literature, prepared during several previous centuries, became inconceivably rapid. The darkest period for Europe generally was about the 7th century. The earliest sign of revival, however, was seen in Ireland as far back as the 6th. In the 10th Italy and England were in a deplorable condition of barbarism, while in France and Germany there was more or less culture, which increased considerably during the 11th. The comparative prosperity of scholastic learning in the 11th and 12th centuries was followed by a relapse in taste and classical knowledge which lasted through the 13th and 14th.

AGESILAUS, king of Sparta, was the son of Archidamus II., and the successor of Agis II. in 398 B. C. He was not the legitimate heir to the throne, but Leotychides, his nephew, being suspected of illegitimacy, was set aside on the death of Agis, by the influence of Lysander, and Agesilaus substituted for him. Agesilaus, having received only the ordinary education of a Spartan citizen, was very popular with the mass of his countrymen, but he was lame and of small stature. Objection was made to him on this ground when Lysander, the conqueror of Athens, proposed him for the succession, and an augur prophesied against him. Lysander replied that a lame-footed king was better than a man who was not of pure Heraclidian blood. Agesilaus submitted to the restraints of a constitutional king and paid court to the ephori. Soon after his accession an expedition against Persia was determined upon. Agesilaus, accompanied by Lysander, accepted the command, and was placed at the head of the council of war. He burst into Asia Minor, 396 B. C., and forced Tissaphernes, the Persian satrap, to beg for a three months' truce, which was sworn to by both parties. It was treach-

erously broken by Tissaphernes, but kept by Agesilaus from considerations both of principle and policy. After many successes in Asia Minor, he marched his army into the government of the satrap Pharnabazus. In a two years' campaign he brought his troops into the highest state of efficiency, and never allowed them to desecrate the temples of the foreign gods. Having overcome all the satraps in the neighborhood, Agesilaus conceived the gigantic scheme of penetrating to the heart of the Persian empire, and meeting the king of Persia face to face, as Alexander afterward did. The money of the Persian monarch, freely used in Athens and Thebes, had meantime stirred up in Greece itself a coalition against Sparta and her allies, and the ephori sent a messenger to Agesilaus recalling him. He returned from Asia Minor by way of the Hellespont through Thrace, Macedonia, and Thessaly, fighting his way when he was opposed, and making the march in 30 days. Xenophon accompanied him. He met the anti-Spartan allies at Coronea in Bœotia (394), and won a well contested battle, in which he was severely wounded and many of his choice body guard of Spartans were slain. He regretted the Corinthian war, because it weakened in a fratricidal struggle those forces which, in his opinion, should have been turned against Persia. His bitter animosity against Thebes led him to screen and support Phœbidas, the Spartan who treacherously seized the citadel of Thebes; and he also saved the life of Sphodrias, who made an equally unprincipled but less successful attempt upon the Piræus. This conduct to states with which Sparta was at peace united Thebes and Athens, and they jointly declared war against the Lacedæmonians. Agesilaus was not present at the defeat of Leuctra (371), after which his state never regained its ancient ascendancy; but he defended the city of Sparta with success against Epaminondas and his allied army. His son Archidamus soon afterward gained an easy victory over the Arcadians, which revived the drooping courage of the Lacedæmonians. The impoverished condition of Sparta after Leuctra was partly remedied by the benefactions of Agesilaus, who gave up to the state all the money and presents which he had received from various oriental potentates. The last scene of his life was held by the Greeks to have been unworthy of his renown. He agreed to aid Tachos, an Egyptian revolter against the Persian monarch, with a band of Laconian mercenaries. When he landed he slept on the shore on straw and under the open sky, though more than 80 years old. The Egyptians could hardly believe that the ill-clad, mean-looking little old man whom they saw before them was he who once held the destinies of Greece and Persia in his hands. Tachos would not give him the supreme control of the land forces, but offered him the post of second in command after himself. This disgusted the old soldier, and when Nectanabis

revolted from Tachos he declared for the former. Nectanabis subjected him to new humiliations, but Agesilaus rescued him from a perilous position, and seated him firmly in power. The Egyptian gave him 220 talents for his services, with which he, in the winter of 361-360, hastened homeward to lay them at the feet of his beloved Sparta, then engaged in war. He never reached home, but died on the coast of Africa, whither he had been driven by a tempest, at the age of about 80, after a reign of 38 years. His body was embalmed in melted wax and taken to Sparta, where he was splendidly buried.

AGGERHIUS, or **Akershuus**, a S. E. bailiwick of Norway, in the diocese of Christiania; area, 2,012 sq. m.; pop. in 1865, 164,804. It abounds in beautiful scenery, mountains, lakes, and waterfalls. The chief trade is in pitch and lumber; with some iron, tallow, and hides. The whole diocese of Christiania was formerly called Aggerhuus.

AGHRIM, or **Anghrim**, a village in the county of Galway, Ireland, 30 m. E. of Galway, famous for the crowning victory of William III. over James II., July 12, 1691. The marquis St. Ruth, a French general, commanded the forces of James 25,000 strong, while Ginkel led those of William, 18,000. St. Ruth had made able dispositions for the battle, but, jealous of the Irish generals, had kept his plans to himself, and when he was killed by a cannon shot early in the action there was no one to succeed him. The English troops, in spite of the well chosen position of their opponents, compelling them to advance through a deep bog, totally routed them, killing, it is said, 7,000, and taking 450 prisoners, while their own loss was only 1,700 killed and wounded.

AGINCOURT, now **Azincourt**, a village in the department of Pas de Calais, France, 7 m. N. E. of Hesdin, on the plains near which, on Oct. 25, 1415, Henry V. of England, with only 15,000 men, defeated the French army of more than 50,000, sent against him by the dauphin (son of the insane king, Charles VI.) and commanded by D'Albret, constable of France, aided by many famous captains. The battle, which lasted three or four hours, was won chiefly through the superiority of the English archers, who almost annihilated the cavalry of the enemy when these had been drawn, by the excellent strategy of the English, into a swamp that lay between the armies. In this desperate conflict the French lost the dukes of Alençon, Brabant, and Barre, the high constable, grand master, and high admiral of France, the master of the crossbows, above 120 princes of the blood and nobles, and 8,400 belted knights, esquires, and gentlemen of birth; of the lower ranks there fell only 1,600 men. Of the English, there fell only the duke of York, the earl of Suffolk, one knight, one esquire, and about 600 men of all ranks and arms. The dukes of Orleans and Bourbon and the high marshal of France, with 1,500 knights and nobles, were

captured, and languished for many years in English prisons.

AGINCOURT, **Jean Baptiste Louis George Se-roux d'**, a French archaeologist, born at Beauvais, April 5, 1730, died in Rome, Sept. 24, 1814. His reputation rests on a work executed in Rome, entitled *Histoire de l'art par les monuments, depuis sa décadence au quatrième siècle jusqu'à son renouvellement au seizième* (6 vols. folio, with 325 engravings, 1823), to which are added analytical tables by M. Genee.

AGIS, the name of four kings of Sparta.—**Agis I.**, who gave name to the Agid line of the joint kings of Sparta, is of uncertain history, but is said to have reigned about 1,000 B. C., to have deprived the conquered people of Laconia of their equality with the Spartans, and to have made slaves of the revolted Helots (citizens of Helos). The following were all of the Proclid line.—**Agis II.** (427-398 B. C.), son of Archidamus II., was actively engaged in the Peloponnesian war, and repeatedly invaded Attica. His son Leotychides being considered illegitimate, he was succeeded by his brother Agesilaus.—**Agis III.** (338-331 B. C.) reigned at the time of Alexander the Great's expedition into Asia. In the absence of that conqueror, he made an irruption into Arcadia, but was defeated with great slaughter by Antipater, the viceroy whom Alexander had left behind him, and fell fighting.—**Agis IV.** (244-240 B. C.), son of Eudamidas II., having come to the throne when he was but 20 years of age, conceived a liberal system of political and social change. The privileged class, who engrossed all the power of the state, and almost all its wealth, and who were alone entitled to call themselves Spartans, had dwindled down to 700 heads of families, of whom not more than 100 were wealthy. As by the laws of Lyeurgus no Spartan citizen could possess more than one lot of land, three fourths of these 100 wealthy proprietors were women, who were not deemed to be affected by the Lyeurgian laws, and in whose hands most of the landed estates had accumulated. Agis himself, his mother, and his grandmother were among the wealthiest proprietors. His plan was, that the great proprietors should give up all their estates above the limit prescribed by Lyeurgus, and that this surplusage should be divided in this way: 4,500 estates, situated in the districts adjoining the city of Sparta, to be given to the poorer Spartan citizens and the most respectable aliens, and 15,000 estates to be cut out from the outlying portions of Laconia, and bestowed on as many Perieci capable of bearing arms, who were to be admitted to Spartan citizenship; all debts to be cancelled, and the whole community to start with a fresh score. He gained over his mother Agesistrata and his grandmother Archidamia, and afterward his other relatives and private friends. The senate rejected the project by a majority of one, but a public meeting was called, when Agis spoke, and offered to give up his property.

Leonidas, joint king with Agis, who with a majority of the property holders was opposed to the scheme, was soon after condemned and deposed for having married a foreigner and resided in a foreign land. A plot was laid to assassinate him, but Agis protected him, and allowed him to leave Sparta unhurt. The ephor Agesilaus, who was deeply in debt, procured a decree to abolish all debts, and all acknowledgments of debt were publicly burned in the market place; but while Agis was absent in command of an army against the Ætolians, Agesilaus intrigued successfully against the fulfillment of the original design. Leonidas was recalled and reinstated, and Agis fled to a sanctuary. The conservatives, not daring to take his life in a temple, kidnapped him while he stole out to take a bath, and threw him into prison. An impromptu trial was held, and he was hurried to execution. His mother and grandmother shared his fate.

AGLAOPHON, a painter of the island of Thasos, flourished about 500 B. C. He was the father and instructor of Polygnotus and Aristophon. There was a later painter of the same name, probably his grandson.

AGMEGUE, or **Gagmeque**, the proper name of the Mohawks, one of the Five Nations of the Hottinossioni or Iroquois. As a tribe they called themselves Gannagwari, "the She Bear," whence they were termed by the neighboring Algonquin tribes Mahaqua, a name corrupted by the English into Mohawk. The French joined the Canada tribes against them in 1609; but the Dutch made a treaty with them in 1618 at Norman's Kill, which proved lasting, and the English also secured their friendship. Yet French Catholic missionaries won many converts among them, who subsequently contributed to build up their three villages on the St. Lawrence. During the French and English wars they did good service against Canada, but in the revolutionary war the tribe under Brant joined the English and committed great ravages in the American settlements. In 1784 they retired to Grand River, Upper Canada, where they now are. The "Mohawk Radicals" of Bruyas is the fullest published dictionary of their language, though Marcoux's grammar and dictionary are the most complete. Brant translated the "Book of Common Prayer" and a part of the Bible into Mohawk.

AGNANO, a lake between Naples and Pozzuoli, about 60 feet deep. The waters are strongly impregnated with mineral matter, and the lake is probably the crater of an extinct volcano. Tradition says there was formerly a town here, which was destroyed by an earthquake; and some antiquaries conjecture that it was the fish pond of Lucullus, who had a villa in the neighborhood. Mosaics and ruins of baths are found. On the shores of the lake are natural sulphur baths (Stufe di San Germano), useful in gout, rheumatism, &c.; and 100 paces from there is the celebrated Grotta del Cane. (See GROTTO.)

AGNES, Saint, according to ecclesiastical tradition, a Christian martyr, of a noble Roman family, beheaded in the persecution of Diocletian in 303, at the age of 16. Her uncommon beauty had tempted a son of the pretor Symphronius, from whose brutality she was saved by a miracle. He was struck blind, and recovered his sight through her prayers.

AGNES SOREL, mistress of Charles VII. of France, born at Fromentean, Touraine, about 1409, died in 1450. She was introduced at court in 1431, soon captivated the king, though she for some time resisted his advances, and retained her influence to the last. So remarkable was her life and conduct in her peculiar position, that for some time she enjoyed the warm friendship of Charles's queen, the virtuous Marie of Anjou. It has been generally asserted that to her was mainly attributable Charles VII.'s recovery from the lethargic despair into which he had fallen, in the hopeless state of public affairs after the English victories of Henry V. and the generals who commanded for his infant son. But her luxury and wealth excited the animosity of the court and the people; and after her sudden death suspicions were entertained against the dauphin, afterward Louis XI., of having poisoned her. She had three daughters by the king.

AGNESI, Maria Gaetana, a learned Italian lady, born in Milan, March 16, 1718, died Jan. 9, 1799. She was the daughter of a professor of mathematics at the university of Bologna. From her childhood she spoke Latin with facility, and was also skilled in other dead and living languages. While still very young she was in the habit of maintaining theses at her father's house, 191 of which he collected and published under the title of *Propositiones Philosophicæ* (Milan, 1738). In 1748 she published her *Istituzioni analitiche* (2 vols. 4to), an educational work on the higher mathematics, partly translated into French in 1775. In 1750, her father having fallen sick, she was permitted by dispensation of the pope to take his place as lecturer in the university. She ended her life in a convent.—**MARIA TERESA**, sister of the preceding, composed the operas of "Sophonisba," "Cyrus in Armenia," and "Nitocris," besides many cantatas.

AGNOËTE (Gr. ἀγνοῦν, to be ignorant of), a sect of heretics in the 4th century, followers of Theophrontius of Cappadocia, and another in the 6th, of Themistius of Alexandria. The former denied the omniscience of God, and the latter held that the union of Christ's human and divine natures did not make his human nature omniscient.

AGNOLO, Baccio d', a Florentine architect, born in 1460, died in 1543. His best works are the Villa Borgherini near Florence, and the campanile of the church of the Santo Spirito in that city. He first introduced the use of frontispieces for the windows and doors of private mansions, which before his time had been confined to church architecture.

AGNONE, a town of S. Italy, province of Molise, 18 m. N. N. E. of Isernia; pop. in 1861, 9,355. It has five *monts de piété*, which make loans of seed corn to the peasants, and is the seat of the principal copper manufactures in the kingdom.

AGNUS DEL. I. In the Roman Catholic church, a cake of wax bearing the image of a lamb holding the banner of the cross, and blessed by the pope. Fragments of such cakes, enclosed in the figure of a heart, are worn around the neck by devout Catholics. **II.** A cloth embroidered with the figure of a lamb, with which, in the Greek church, the cup at the Lord's supper is covered.

AGOBARD, Saint, a Frankish theologian, born in 779, died June 6, 840. He became archbishop of Lyons in 816, and was deposed by the council of Thionville in 835 for the part he had taken in the revolt of Lothaire against Louis le Débonnaire (833), but was promptly restored, having become reconciled with the emperor. He wrote several controversial theological works against image worship, the belief in witchcraft, and duelling; his principal opponent in discussing these questions was Felix of Urgel. Editions of Agobard's works were published in 1605 and in 1666 in Paris, and a book of his against the Jews was translated into German in 1852.

AGONIC LINE (Gr. *a*, without, and *γωνία*, angle), a word introduced by the modern investigators of terrestrial magnetism, and applied to a line uniting all points where the declination of the compass needle is zero, that is, where it points exactly north and south. As the mag-

netic poles of the earth do not coincide with the geographical poles, the magnetic meridians are different from the geographical meridians; and as the former are determined by the declination of the compass needle, they are by no means regular arcs of great circles, as is the case with the latter, the magnetic force which directs the compass needle being very irregular over the earth's surface. Therefore the agonic line is not that geographical meridian which passes through the magnetic poles of our earth, but an irregular line at present crossing the eastern portion of South America at about 20° S. latitude and 30° of longitude E. of Washington, skirting the Antilles, entering North Carolina near Cape Lookout, passing over Virginia, Ohio, Lakes Erie and Huron, crossing through the Dominion of Canada, and reaching Hudson bay and the magnetic north pole. At the other side of this pole it passes through the unexplored regions of the geographical north pole till it reaches the northern coast of Siberia in about lon. 115° E. of Washington, and lat. 75° N., passes south through the Caspian sea and the Persian gulf, then bends southeast through the Indian archipelago, crosses the continent of Australia in about lon. 190° E., and then takes a more southern direction to the as yet undiscovered magnetic south pole, beyond which it undoubtedly passes through the south polar regions to unite again with the agonic line in the southern Atlantic ocean. A most perplexing fact is the discovery that there is in the eastern hemisphere a second agonic line, independent of the main one just described. It enters China from the south in lon. 185° E., runs north through Tartary, reaches Siberia in lat. 65° N., then bends toward the east, then southeast, when it enters the ocean; it runs southward over Japan, then southwest, and finally west, and unites with the line entering the south of China. It thus forms a closed elliptical ring, nearly 2,500 m. long and 1,500 m. wide, inside of which the declination of the compass needle is eastward. If the modern theory be correct, that the earth's magnetism is caused by electric currents running from east to west through the earth's crust, and to which, according to the law of Oersted, the compass needle places itself at right angles, these peculiarities would only indicate that the direction of these currents is somewhat irregular, and that they only run exactly east and west at the localities through which the agonic lines have been traced. The most difficult phenomenon, however, is the fact that both this agonic line and the magnetic pole have a slow motion from east to west; in 1580 it ran through Sweden and Germany, in 1620 through Holland, in 1660 through London, England, in 1700 through the western coast of Ireland; it arrived on the American continent about 1780, and in Pennsylvania in 1800; it is now in Ohio, and constantly moves west with a velocity which seems to indicate that, if persisted in, it will make one revolution around the earth in about 600 years. Trustworthy observations, however, extend thus far over too short a period of time to warrant any legitimate conclusion.

AGONISTICI, a sect of Donatist ascetics who inhabited the northern part of Africa in the 4th century. They were opposed to labor, and to marriage as well as to monasticism, which was then just beginning to gain ground. They were mostly rough, uneducated peasants, who begged among the inhabitants, and often destroyed the idols, regardless of the martyrdom which was frequently their reward. They eagerly sought a voluntary death by means of fire or water. Upon the invasion of the Vandals the sect was totally extinguished.

AGOSTA, or *Augusta*, a seaport town on the E. coast of Sicily, 12 m. N. of Syracuse, and 18 m. S. of Catania; pop. in 1861, 9,223. It is built on a low peninsula in the Mediter-

netic poles of the earth do not coincide with the geographical poles, the magnetic meridians are different from the geographical meridians; and as the former are determined by the declination of the compass needle, they are by no means regular arcs of great circles, as is the case with the latter, the magnetic force which directs the compass needle being very irregular over the earth's surface. Therefore the agonic line is not that geographical meridian which passes through the magnetic poles of our earth, but an irregular line at present crossing the eastern portion of South America at about 20° S. latitude and 30° of longitude E. of Washington, skirting the Antilles, entering North Carolina near Cape Lookout, passing over Virginia, Ohio, Lakes Erie and Huron, crossing through the Dominion of Canada, and reaching Hudson bay and the magnetic north pole. At the other side

ranean, and in consequence of its liability to earthquakes, by one of which it was almost totally destroyed in 1693, the houses, with a few striking exceptions, are built low. On the west side of the peninsula it has a commodious harbor, said to be one of the best in Sicily. The knights of Malta at one time had extensive magazines at this port. Agosta has a trade in wine, flax, olive oil, salt, honey, and sardines. The remarkable caves of Timpa are near the town. It was founded in the 13th century by the emperor Frederick II., who destroyed the town of Centuripa and removed its inhabitants hither.

AGOSTINO and **Agnolo** or **Angele**, two brothers, sculptors and architects, born at Siena about 1269. Educated in their profession by Giovanni, a Pisan architect, they were named architects of their native city, where they constructed many edifices for secular and religious uses. They also executed, from the plans of Giotto, the tomb of Guido, bishop of Arezzo, one of the finest architectural monuments of the 14th century.

AGOULT, **Marie Catherine Sophie de Flavigny**, countess d', a French authoress, known by the pseudonyme of Daniel Stern, born in Frankfort-on-the-Main in 1805. Her father, the viscount de Flavigny, emigrated to Frankfort during the revolution. She was educated in Paris, and in 1827 married Count Hector Philippe d'Agout. She subsequently travelled much in Switzerland, Italy, and Germany, separated from her husband, and lived with Liszt, the pianist, by whom she had children. She was afterward reconciled with her husband (who died in 1856) and regained her social standing in Paris. She wrote a series of novels somewhat after the style of George Sand. Her principal work is *Histoire de la révolution de 1848* (2 vols., 1851; new edition, illustrated, 1866). She has also published *Trois Journées de la vie de Marie Stuart* (1856), *Florence et Turin* (artistic and political essays, 1862), and *Dante et Gæthe* (dialogues, 1866).

AGOUTI (*dasyprocta* of Illiger; *chloromys* of Cuvier), a genus of animals belonging to the class *mammalia*, order *rodentia*, dis-

Agouti (*Dasyprocta aguti*).

tinguished principally by their feet and toes, which are furnished with powerful claws, similar to those of the burrowing animals. The agoutis, however, neither burrow nor climb,

roaming at large in the forests, and sheltering themselves among any casual defences they may find. They use their fore paws for the purpose of holding their food, sitting erect on their haunches while eating, and assuming the same attitude when looking about them or listening in alarm or surprise. The agouti is of nearly the size of a large hare, and like that animal has its hind legs longer than the fore, but not so disproportionately, for which reason it stands more erect. The common agouti, *D. aguti*, measures about 1 foot 8 inches in length, and stands 11 or 12 inches high at the croup. Its head resembles that of the rabbit; its face is convex; its nose swollen; its upper lip cleft; its ears round and naked; its eyes large; its upper jaw longer than the lower; and its tail a mere naked stump. The hairs on the upper parts are annulated alternately with black, brown, and yellow, producing a speckled yellow and green appearance on the neck, head, back, and sides. The croup is golden yellow; the breast, belly, and inner part of the arms and thighs are straw color; the moustaches and feet black. The hair on the fore parts is about an inch long; on the rump nearly four times that length, whence the generic name of *dasyprocta* (hairy-rumped); and is everywhere, except on the breast and belly, of a stiff and bristly character. These animals inhabit Guiana and Brazil, and are also found in the West India islands, and as far south as Paraguay. On the islands, at the time of their first discovery, they were the largest known quadrupeds, and constituted the principal food of the dense Indian population. It is asserted and denied, by different authors, that they breed many times in each year, and produce many young at each birth; but the great numbers in which they are still found in all the hotter parts of America, in spite of their destruction by the small carnivora and by the Indian races, together with their affinity to the rabbit and cavy, seem to countenance the affirmative proposition. Their flesh is white and tender, and is cooked like that of the hare or rabbit. The other varieties of this animal are the black or crested agouti, *D. cristata*, of Guiana and Brazil; the acouchy, or olive agouti, *D. acouchi*, of the West India isles, Guiana, and the northern parts of Brazil; the white-toothed agouti, *D. croconata*, of the Amazon; the black-rumped agouti, *D. pnyuolopha*; the sooty agouti, *D. fuliginosa*, of northern Brazil, easily distinguished by its black color and great size; and, lastly, the Azara's agouti, *D. Azara*, of Paraguay, Bolivia, and the south of Brazil. They are perfectly harmless, and appear to form a link between the families of the rabbit and cavy or Guinea pig.

AGRA. I. One of the six Northwest Provinces of British India (which constitute one of the eight separate administrations into which India is divided), lying nearly in their centre; area, 9,479 sq m.; pop. about 4,500,000, all Hindoos, except nearly 400,000 Mohammedans.

It is watered by the Jumna, Ganges, and Chumbul, is generally flat, almost treeless, and arid, but by irrigation produces good crops of millet and other grains, indigo, cotton, pulse, &c. **II.** One of the six districts or zillahs of the province of Agra; area, 1,865 sq. m.; pop. about 1,000,000. **III.** A city, capital of the preceding province and district, and formerly of the Northwestern Provinces, on the S.W. bank of the Jumna, connected by railway with the principal Indian cities, 115 m. S. S. E. of Delhi and 783 m. N. W. of Calcutta; pop., including the two suburbs and the garrison, about 125,000. It is the centre of an extensive trade, chiefly in cotton, sugar, indigo, salt, and silks. The ancient walls embrace an area of nearly 11 sq. m., about half of which is occupied. Inside Fort Akbar are the palace of Shah Jehan and the famous pearl mosque. Near the river, about 1 m. E. of the fort, is the celebrated Taj Mahal, a mausoleum built by Jehan for himself and his

century Agra was embellished and fortified by Akbar, whose tomb is 6 m. from the city. In 1658 the capital was removed to Delhi. From that time the population, then estimated at nearly 500,000, began to decline, but it has increased since the British occupation. In the 18th century Agra was held by various native rulers, and eventually by Madhaji Sindia, the Mahratta chief, patron of the French adventurer Pirron, who during the conflict in 1803 with the East India company employed in his turn the Dutch adventurer Hessian. Anarchy prevailed in the garrison, and several Mahratta regiments joined the English forces under Gen. Lake, who occupied the city in September, and the fort in October, 1803. During the sepoy mutiny of 1857 most of the European houses were destroyed. The English and other foreign residents, however, shut themselves up in the fort and sustained a gallant defence until relieved by Col. Greathed.—Agra is venerated by the Hindoos as the city of the incarnation of Vishnu under the name of Parasu Rama.

AGRAM (Croat. *Zagreb*; Hun. *Zágráb*), a town of the Austro-Hungarian monarchy, capital of Croatia and of a county of its own name, about a mile from the river Save, and 160 m. S. of Vienna; pop. in 1869, 20,637. It is the residence of the ban of Croatia, and the see of a Roman Catholic archbishop. It carries on an important trade in salt, tobacco, grain, and wines. In its vicinity is one of the finest parks of the monarchy.

AGRARIAN LAWS, enactments framed at various times by the Romans to regulate the *ager publicus*, or public domain. In the first epoch of the growth of Rome, when the city had not yet extended beyond the Palatine hill, the whole soil of the state was *ager publicus*, or undivided public property; and from the state, or the *populus Romanus*, consisting exclusively of citizens, every citizen received a share for his private use. In principle all the land was, therefore, *ager publicus*, and the citizen could only acquire possession as tenant at will of the state; but in course of time the descendants of the original founders, or the patricians, transformed these primitive concessions into an absolute right, called in the Roman law *de jure quiritio*. Still the principle remained, and was recognized during the whole epoch of the republic, that all lands and booty acquired by conquest were acquired for the state, and could only become the property of individuals through the cession to them of the rights of the state. As conquest increased the public possessions, and the class of plebeians was formed, the Roman people gave them lands in the *ager publicus*, as private property, on condition of their paying a tribute, and undertaking other public services; but the patricians always preserved their ancient right of receiving in possession and using parts of the public domain, on paying to the public treasury a tithe of its product. From the first epoch of Roman society, lands thus held could pass as an inherit-

The Taj Mahal, Agra.

wife Noor Mahal, in the construction of which 20,000 men are said to have been employed 22 years; the cost was estimated at over \$4,000,000. It is of white marble, 100 feet in diameter and 200 in height, built in the form of an irregular octagon, and rising from a high marble terrace which rests upon another of red sandstone. At the corners of the marble terrace are lofty minarets, and in the centre of the main building rises a dome, flanked by cupolas of similar form. Both the interior and exterior are decorated with mosaics of precious stones and the most beautiful tracery. The whole Koran is said to be written in mosaic of precious stones on the interior walls. The sarcophagi of Jehan and Noor Mahal lie in the crypt below. Among the European public buildings is the government house, the seat of the lieutenant governor of the Northwestern Provinces, who is sometimes called lieutenant governor of Agra, the province having been at first destined (in 1833) to form a separate presidency.—In the 16th

ance to children, and were even sold under this precarious tenure, though in principle the state could always resume their possession. These public lands were also, on their conquest, often transformed into common pasturage. Such lands had various technical names, as *occupati*, *occupatorii*, *concessi*, *arceifinales*, &c.; but the general name was that of *possessionses*, and the payment or title given to the state for their use was called *fructus* or *vectigalia*. The possession of all such lands by individuals was permissive, and differed wholly from the absolute right of property, by which each Roman citizen, whether an original patrician or one of the plebeians who were first admitted to private and then to public rights, held landed property by the various titles and denominations known in the Roman law. But the patricians, the original shareholders in the public domain, became by long use accustomed to consider their grants as absolute property, especially as they had improved them in various ways; and accordingly they often refused to pay the title due to the treasury. In the early period of the republic, previous to the twelve tables, Spurius Cassius, a patrician, on becoming consul, procured a law that some parts of the public domain, long before conquered, but occupied by the patricians, should be surrendered to the state and assigned to the necessitous citizens. The patricians resisted it, and the law remained a dead letter. The patricians not only prevented new divisions of the public lands, but by violence or usury acquired those of the plebeians. This led to agitation for a revival of the law of Spurius Cassius, which the celebrated decemvir Appius Claudius strongly opposed. Next, the invasion of the Gauls under Brennus ruined the numerous small free tenants and freeholders, and obliged them to sell their landed property to the wealthy patricians. Those among the small freeholds which were not thus absorbed were overwhelmed by the surrounding large estates. The keeping of large flocks of cattle ruined the *saltus publici*, or common pasture lands, and in fact excluded the small farmers from them. This abuse occasioned the publication, in 367 B. C., of the Licinian law (*rogationes Liciniae*), so called from Licinius Stolo, its originator. This law is considered as forming the basis and containing the essence of the agrarian idea. The technical name of this law was *De Modo Agri*. It prescribed, under a penalty of heavy fines, that no one should possess more than 500 *jugera* (about 330 acres) of the public domain; and that no one should send to graze on the public pastures more than 100 large or 500 small animals. This law was put in force for a brief period, after which it was neglected for nearly two centuries, when it was renewed by Tiberius Gracchus, with some additions and modifications in favor of the wealthy, who were mostly patricians. Any one having one or two sons could hold from 250 to 500 *jugera* in the public domain above his original

right, as established by the Licinian law. The attempt to execute these laws occasioned the tragical end of the two Gracchi (133 and 121 B. C.). In succeeding times, an agrarian law was mooted by a certain Saturninus, having for its object the distribution of lands conquered in Cisalpine Gaul. Another was proposed by Drusus to distribute all the conquered lands among the poor; and in the time of Cicero, Servilius Rullus proposed that the public domains out of Italy conquered by Pompey should be sold, and out of the proceeds lands bought in Italy for needy citizens. Not one of all the Roman agrarian laws was ever executed, and not one of them had that confiscatory or leveling character so frequently attributed to them. Not one of these laws aimed at the equal division of landed property owned by individuals in their own absolute right, or intended any limitation upon such ownership.

AGREDA, Maria de (Corenel), a Franciscan nun, lady superior of the convent of the Immaculate Conception (founded by her mother) at Agreda, in Spain, born in that town in 1602, died there, May 24, 1665. She professed to receive revelations direct from heaven. At the command of God, who appeared to her in a dream, as she said, she undertook to write the life of the Virgin Mary. It was first published in 1690, under the title *Mistica Ciudad de Dios* (4 vols.). Every word, according to her attestation, had been written under inspiration. The reading of it was forbidden at Rome, and the Sorbonne in Paris censured the individual who translated a portion into French. Bossuet exposed the indecencies of the work. It has been translated into German.

AGREEMENT. See **CONTRACT**.

AGRIE, Agreeb, or Gharib, Mount, a remarkable conical mountain in central Egypt, in lat. 28° 12' N., lon. 32° 42' E. It is situated about 16 miles inland from the gulf of Suez, opposite Mt. Sinai, is about 6,000 feet high, and can be seen at a distance of 100 miles.

AGRICOLA, Cneius Julius, a Roman general, born at Forum Julii (now Fréjus in Provence), June 13, A. D. 37, died Aug. 23, 93. He received his education at Massilia (Marseilles), and his military training under Suetonius in Britain. On Vespasian's election by his legions (69), Agricola, then quaestor in Asia, was one of the first to acknowledge him, and that emperor in gratitude appointed him governor of Aquitania. He was next made consul, and subsequently governor of Britain. During this governorship he conquered Wales and the island of Anglesea, built a wall from the Clyde to the frith of Forth to keep off the incursions of the northern barbarians, and defeated the British Galgacus in Scotland, and thus brought Britain under complete subjection. The Roman fleet now for the first time sailed round the whole island. He was recalled by Domitian, and lived in retirement till his death, which was attributed to the emperor's jealousy of his military reputation and popularity. His daughter Do-

mitia married Tacitus the historian, who wrote his life.

AGRICOLA. I. Georg, a German mineralogist and physician, born at Glauchau, Saxony, March 24, 1490, died in Chemnitz, Nov. 21, 1555. His name was originally Bauer (peasant), of which he adopted the Latin equivalent. He was at first rector of a school in Zwickau, afterward studied medicine at Leipsic, devoted himself to metallurgy, and in 1531, on the invitation of Duke Maurice, settled at Chemnitz. He attempted to reduce mineralogy and metallurgy to a science, and introduced considerable improvements in the previously rude art of mining. He first made chemical analyses of the different earths. His mind was, however, deeply tinged with the superstitions of his age. Having renounced Protestantism before his death, his body was refused burial in Chemnitz. He wrote *De Re Metallica*, *De Ortu et Causis Subterraneorum*, and *De Mensuris et Ponderibus Romanorum atque Græcorum*. **II. Johann Friedrich**, a German musician and composer, born near Altenburg, Jan. 4, 1720, died in Berlin, Nov. 12, 1774. He studied music under Sebastian Bach, was chapelmaster of Frederick the Great, and wrote several operas, among them "Iphigenia in Tauris." He was husband of the vocalist Mine. Molteni. **III. Johannes** (originally SCHNITZER or SCHNEIDER), a German theologian, born in Eisleben, whence he is called Magister Islebius, April 10, 1492, died in Berlin, Sept. 22, 1566. He studied at Wittenberg and Leipsic, and acquired the friendship and esteem of Luther, who in 1525 sent him to Frankfort-on-the-Main, to institute Protestant worship there. On his return he was parish priest of Eisleben, and here he commenced that Antinomian controversy which he subsequently renewed from his professorial chair in Wittenberg (1536-8), and for which he was dismissed from that university. He next became chaplain and general superintendent to the elector of Brandenburg. He wrote several theological works, as well as an account of the common German proverbs. **IV. Rudolf**, an eminent scholar, born in Groningen in 1442 or 1443, died in Heidelberg, Oct. 28, 1485. He travelled in France and Italy, and won the esteem and patronage of Ercole d'Este, duke of Ferrara. On his return he was chosen professor of philosophy at the university of Heidelberg. He wrote various works of a miscellaneous character, the most remarkable of which, perhaps, is an essay entitled *Tractatus de Inventionem Dialecticam*, in which he devotes considerable space to the discussion of the ability of deaf mutes to acquire such knowledge of language as to be able to converse with others by writing. He was among the first to introduce the study of Greek into Germany, and gave lectures on Greek literature at Worms and Heidelberg.

AGRICULTURAL CHEMISTRY, the study of the chemical relations of substances concerned in agricultural production. The whole natural

science of vegetable and animal production is usually called agricultural chemistry, although it includes much of physics, meteorology, vegetable and animal physiology, and geology. It is impossible to separate these subjects, without grave errors; and hence those works which give the justest view of the chemistry of agriculture are not strictly treatises on agricultural chemistry. The object of agriculture is to develop from the soil as large a quantity as possible of useful vegetable products; or indirectly, of animal products. To assist in this, agricultural chemistry must inquire into the composition of the plant and animal. It finds that all vegetable and animal substances contain a variable, usually large proportion of water, which is essential to their life, but may be separated from them by heat without otherwise affecting their chemical composition. At a high temperature, dry animal or vegetable tissues are resolved into two portions; one passes into the air as volatile gases or vapors; another, indestructible by heat, remains as ashes. In most vegetable and animal substances, the combustible or organic part forms 90 to 99 per cent. of the whole dry matter; the proportion of inorganic substances (ash) being small. The organic matter mainly consists of four elements, viz.: carbon, oxygen, hydrogen, and nitrogen. These simple bodies are united in the plant and animal into thousands of combinations, the extended study of which belongs to organic chemistry. Most agricultural products, however, consist chiefly of but a few of these combinations or proximate elements. These may be specified under four classes: 1. The oils and resins, including wax. 2. Cellulose (cell tissue, woody fibre); starch; the sugars, cane and grape; the gums, arabine, bassorine, dextrine (starch gums). 3. Pectose (the pulp of green fruits) and its derivatives. 4. The nitrogenous or sanguiniferous* principles, viz.: albumen, caseine (legumine, avenine), emulsine, and fibrine (gluten). The first three groups are composed exclusively of carbon, hydrogen, and oxygen (some of the oils, of carbon and hydrogen only), while all the members of the fourth group contain 15 to 18 per cent. of nitrogen, most of them small quantities of sulphur, and phosphorus also, in addition to the three elements above named. The whole growing part of the plant is a porous substance, as easily penetrable by air as a sieve, and a hygroscopic substance, absorbing and retaining the vapor of water from the air or soil with great force and obstinacy. When a vegetable is destroyed by burning, it is mostly resolved into air. On the other hand, when it is formed by growth, its substance is mostly derived from air. The atmosphere which perpetually bathes and penetrates the leaves of plants supplies them with carbon, hydrogen, nitrogen, and oxygen. The atmospheric source of carbon is carbonic acid. This gas is a constant ingredient of the atmos-

* *Blood-producing*; so called from the function of these bodies in animal nutrition.

phere to the extent of $\frac{1}{2500}$ of the volume of the latter. It is rapidly absorbed by the leaves of growing plants under the influence of sunlight, and undergoes decomposition in the vegetable cells, carbon being retained and assimilated, while the oxygen is set free wholly or in part, and exhales from the leaves. Water, which always exists in the atmosphere in the state of vapor, is an abundant source of both oxygen and hydrogen. Ammonia, a compound of hydrogen and nitrogen, is the chief source of nitrogen to the plant. It is ever present in the atmosphere in the form of carbonate, though in exceedingly small quantity. Nitric acid, which is formed by the oxidation of ammonia, is also a source of nitrogen. The plant being fixed and at rest, its food must necessarily be in perpetual motion around the organs destined to take it up. The atmospheric food is kept in motion, not only by the winds, but more effectually by the osmotic force (exosmose and endosmose). When two or more gases of unequal density are brought in contact in a confined space, they will gradually diffuse into each other, until they form a homogeneous mixture. If into a mixture of gases any solid or liquid body be introduced, which can combine with and remove one of the gases, it first takes up those particles of this gas which are in its immediate vicinity; but as fast as the uniformity of the mixture is thus disturbed, the absorbable gas diffuses into the space which has become void of it; and as new portions are removed, other new ones are presented, until the whole is absorbed. All the forms of plant food are soluble in water. In virtue of these physical laws, it is plain that the tissues of a growing plant must be constantly surrounded with water, and with carbonic acid and ammonia dissolved in this water; and as these are removed by the assimilating processes of the vegetable, they are restored by osmotic diffusion, so long as the atmospheric supply suffices.—The ash of agricultural plants consists of the phosphates, sulphates, silicates, and carbonates of potash, soda, lime, and magnesia, with small quantities of oxide of iron and manganese, and alkaline chlorides. Other bodies, as alumina, copper, and zinc, are found in some kinds of land plants. The living plant contains sulphur (and perhaps phosphorus) in a state of organic combination, in the various nitrogenous principles, or in sulphurized oils. On burning these compounds, sulphuric and phosphoric acid result. Portions of the potash, soda, lime, and magnesia are combined with vegetable acids (oxalic, tartaric, malic) in the living plants, but these compounds are converted into carbonates by burning. Silica exists probably in the uncombined state in many cases, as in the bamboo (*tabasheer*), stalks of grasses, and scouring rush; but in burning it combines with potash, lime, &c., so that it is found as a silicate in the ash. That these ingredients of the ash are indispensable to the development of vegetation, is proved not only by their invariable occur-

rence in normally developed plants, but by direct experiment. The cereal grains, for example, will not mature in a soil which is deficient in any one of the following substances, viz.: potash, soda, lime, magnesia, oxide of iron, oxide of manganese, silica, sulphuric acid, phosphoric acid, chlorine. These kinds of plant food are all derived from the soil, and enter the plant through its roots. The medium of their transmission into the vegetable organism is water, which is assisted in its solvent action by carbonic acid and ammonia. The same law of osmotic diffusion, which accumulates the gaseous food of the plant in the tissues of the leaves, keeps up a supply of food from the soil. Evaporation from the surface (foliage and stems) removes from the plant a portion of the water which the cells contain. Capillary action restores this waste of water, bringing up from the soil a fresh supply, which always contains mineral matters in solution. The vague idea of the older vegetable physiologists, according to which there is a constant circulation of sap in plants, an upward and a downward flow—the sap ascending in the outer wood to the leaves, there being elaborated, and returning through the inner bark to the roots, depositing new matter on its way—must be noticed here, as an exploded but still oft-repeated error. There is no evidence that there exists any but an upward and outward current—a current toward the vaporizing surfaces. The amount of ash and the proportion of its ingredients are different in different classes of plants, and in the various parts of the same plant. As a general rule, the exterior or terminal parts of plants, as the bark, leaves, and chaff or fruit envelopes, give the most ash, 7 to 28 per cent.; while the wood of trees is poorest, yielding but $\frac{2}{10}$ to 3 per cent. The same organ contains different quantities of mineral matters at different stages of its growth. Doubtless, part of the substances which we find in the ash of a mature plant have finished their active functions, and have been secreted as waste matters. Doubtless, too, a part of the ash is accidental, not necessary to or employed by the plant, but having entered the vegetable circulation merely from being dissolved in the water which the plant has absorbed. For these reasons there is often little agreement between the numerous analyses which have been executed on the ashes of the same species or even variety of plant, its composition being to a certain extent influenced by the kind of soil in which it grows. Yet there is a general uniformity of composition, and it is undoubtedly true that the organization of the elements, carbon, hydrogen, oxygen, and nitrogen, into the cell tissues, and their contents, requires the coöperation of the ingredients of the ash, and that the relation between them is quantitative and definite, though we may never be able to determine it accurately.—The atmosphere is invariable in composition, and furnishes supplies of oxygen, hydrogen, carbon, and nitrogen (water, car-

bonic acid, and ammonia), beyond what the natural vegetation of any country needs. The soil is exceedingly variable in composition. When it can supply sufficient quantities of ash ingredients, it will produce most of the plants indigenous to its locality. It then is fertile. When there is a deficiency of ash ingredients in available form, or the absence of any one of them, the soil is barren. There is an important difference between natural, spontaneous growth, and artificial, forced production. Natural growth in general is slow. Cultivated growth is rapid. For the former, natural supplies are sufficient; for the latter, artificial supplies must be provided. For the former the supplies of atmospheric food are in excess compared to those of ash ingredients yielded by the soil (telluric food), so that in forests and prairies the former accumulate on the surface of the soil as dead foliage, which in its decay becomes a telluric source of atmospheric food. In the latter the reverse most usually occurs, so that the organic matter of the soil diminishes and must be renewed by manures. To repeat, in artificial growth (intensive culture) the soil is made to perform not only its natural function of furnishing ash ingredients, but also a part of the office naturally left to the atmosphere, viz.: the supply of carbonic acid and ammonia.—Soils consist of the more or less comminuted fragments of rocks, mixed with certain products of their chemical decomposition, and with some organic matter—*débris* of vegetation. The composition of the soil varies according to the rocks from which it originates. It is rare that large tracts of soil are exclusively derived from the rocks that now underlie them. Most of the soils of our northern and middle states are partly composed of materials transported from the far north during what geologists term the drift period. The soils of valleys are constantly enriched from the rocks of surrounding hills, so that the composition of soils is thus more uniform in a general sense than it otherwise could be. We constantly meet, however, with limited areas having soils of peculiar characters. We find beds of sand, gravel, clay, marl, and peat or muck. The mechanically coarser parts of soil, the gravel and sand, consist of the still undecomposed fragments of the rocks from which it has been formed. A part of the finest (impalpable) portion of every productive soil is usually made up of clay, which is a product of the chemical decomposition of certain minerals, and which possesses properties of the highest moment in agriculture. Under the general name *humus* is comprehended the organic matter of the soil which has resulted from the partial decay of previous generations of plants. The mechanical texture and other physical characters of the soil have a controlling influence on its fertility. Unless the soil be permeable by the roots of plants, and preserve the proper degrees of warmth and moisture, vegetation cannot attain its maximum development,

no matter how favorable may be its chemical composition. Assuming then that the soil is physically adapted for a cultivated vegetation, its fertility depends upon its furnishing the growing plant with continuous and abundant supplies of the different bodies that have been named as the elements of vegetable nutrition. The quantity of ash ingredients that the heaviest crop removes from a soil is small, compared with the whole weight of the soil taken to such a depth as is penetrated by the roots of plants. In average crops of the usually cultivated plants, those portions which are removed from the field as the valuable part of the crops do not carry off more than 200 to 600 lbs. of ash ingredients per acre yearly, while the soil taken to the depth of one foot weighs three to four millions of pounds per acre. That part of the soil which is soluble in the water of rain represents its available plant food. Large quantities of water pass through the vegetation of every acre of highly cultivated ground. It is only needful, then, that this water should contain a few thousandths of ash ingredients in solution, in order to supply the mineral matters in an average crop, since even root crops, *e. g.* beets, remove but about 600 lbs. of these substances from the acre. In cultivated soils there is a constant removal of available ash ingredients, both by the harvests that are taken off, and by the rains which soak through or run over them. In a productive soil there is a constant renewal of available plant food, by the mechanical and chemical disintegration of the insoluble portion (the pulverization of the soil by the operations of tillage), by the alternate contractions and expansions of water (frost), and by the affinities of oxygen and carbonic acid. In a few rare soils the disintegrating and solvent processes are so rapid (act on such finely divided or easily decomposable materials), that they always present a surplus of food to the plant. Such are certain soils of southern Russia (*techernozem* or black earth), and of the Scioto valley, Ohio. They yield successive crops for many years without manure. In most cases, however, the removal of a few crops exhausts the store of available plant food.—Soils, when reduced in fertility, may be restored to productiveness by lying in fallow; mechanical and atmospheric agencies thus bring into solution enough of ash ingredients for a new crop. A soil consisting entirely of coarse sand is infertile, because it is too dry, and because there can occur in it no sufficient accumulations of available plant food. A soil consisting of fine sand may be highly productive, especially if it originates from easily decomposable rocks, because the amount of surface that the grains expose, and the close texture of the soil, maintain it in a proper degree of moisture (by capillarity), and allow a sufficient solution and accumulation of food for crops. Clay has a remarkable porosity and retentiveness for water, for ammonia, and for

most soluble salts. If dilute solutions of ammonia, potash, soda, magnesia, &c., be agitated for a few moments with clay, or allowed to filter through it, a portion of these bodies is removed from solution, and absorbed by the clay. Putrid urine loses both odor and color by such treatment. The use of salts of alumina as mordants, and for the preparation of lakes, is another example of the same effect. Soils too rich in clay are heavy, and in wet climates intractable from their physical properties; but in dry countries like Egypt, or when mixed with enough sand to render them physically adapted to the growth of plants, they usually possess a great and durable fertility, since they naturally abound in the aliment of vegetation, and are not liable to suffer loss of their soluble matters from the washing effects of rains or floods. Organic matter (humus), when formed in wet places, constitutes muck and peat, which are not fertile; but as it occurs in arable soils, in quantities usually not exceeding 3 to 10 per cent., it is of great value, not only on account of its power of absorbing water, &c., but also from the fact that in its decay it is a continuous source of carbonic acid and ammonia, thus satisfying to some extent one condition of rapid growth, already insisted upon, viz.: supplies of atmospheric plant food by the soil. The carbonic acid formed in the soil by the slow oxidation of humus acts also, according to the amount of its production, in the chemical disintegration of the insoluble parts of the soil, and thus indirectly furnishes to the plant increased quantities of ash ingredients. Until Liebig turned his attention to the applications of chemistry to agriculture, it was thought by the most eminent philosophers that humus in some of its forms was the chief nutriment of plants. Liebig denied its immediate value as plant food, but recognized its use as an indirect supply of carbonic acid and ammonia. The best soils always contain soluble organic matter, and, although it has not been proved that cultivated plants are directly fed upon it, yet there is evidence that some of the lower orders of vegetation do assimilate it, and there is no reason to suppose that it may not be appropriated by agricultural plants, since it is sufficiently soluble to find its way into their circulation.—*Analysis of Soils for Economical Purposes.*—When chemistry first indicated the relation between the composition of the soil and that of the plant, and showed that certain instances of barrenness and fertility in the former could be explained by the results of chemical analysis, the idea that the farmer might profitably employ analysis in improving his soil took deep root. A few considerations will suffice to show, however, that as a general rule even the most accurate analysis can be of no practical benefit. Saying nothing of the facts that the productiveness of a soil often depends on its physical or chemical condition irrespective of composition, that it is in most cases impracticable to get a specimen of soil

that shall fairly represent a large field or farm, and that the expense of a thorough and faithful analysis is considerable, it is impossible in the present state of science to distinguish from each other two soils, one of which is just fertile and the other just barren; for the processes that have been usually employed in soil analysis are not nice enough to estimate quantitatively differences of 1-10th per cent. with invariable accuracy. Now, since an acre of soil, taken to the depth of only 7 or 8 inches, weighs at least 2,000,000 lbs., and since the total amount of matter withdrawn from the soil by the heaviest crops rarely exceeds 500 lbs., 1-4000th of the whole, it is folly to expect that analysis can indicate any difference in the composition of a soil before and after one, two, or even three crops have been removed from it. Again, there are numerous instances of soils naturally sterile, which, after application of 400 lbs. of guano, manifested a wonderful productiveness. Now, the largest of the active ingredients of guano never amounts to 20 per cent.; so that to trace its action, or distinguish between two soils, one barren and the other made fertile by guano, the chemist must be able to estimate 100 parts in 2,000,000, or a fraction so small as $\frac{1}{20,000,000}$. The only method of chemical examination that promises to be useful is the following: A large quantity of soil, say 10 or even 100 lbs., is digested and exhausted with water saturated at ordinary temperatures with carbonic acid. In this way we dissolve all its "presently available plant food." The analysis of this dissolved portion might be expected to give insight into the value of the soil so far as dependent on chemical composition. Dr. Peter, chemist to the Kentucky geological survey, has recorded in his report some results obtained in this way, except that instead of exhausting 10 lbs. of soil, he used but 1,000 grains. The amount of dissolved matters in his trials in no case exceeded 7 grains, while it usually fell below 2 grains, quantities too small for accurate analysis. For practical purposes there are, however, other and in general simpler means of ascertaining the ability of a soil to supply food for remunerative crops. Thus the character and amount of vegetation which it naturally produces generally suffice to indicate with certainty the value of a new soil in this respect. In nearly all cases of unproductive soils, the difficulty is less of a chemical than of a physical nature. The great deserts are sterile, not because they cannot yield the soil food required by vegetation, but because they are destitute of water. Wherever a spring arises in them, there is formed a spot of verdure, notwithstanding the incessant sunshine and parching winds. Some soils, however, with every external sign of fertility, are nevertheless barren, because deficient in some one or several of the indispensable constituents of the ash of plants. To ascertain and remedy these deficiencies, it is best to proceed in a synthetical rather than in the analytical man-

ner, viz.: to make trials, on separate plots of ground, of the effect of adding to the soil those ingredients which are most likely to be wanting. The improvement of the soil involves numerous changes, both in its physical and chemical characters. The correction of the physical qualities of the soil usually effects a marked improvement in its chemical condition. It is at any rate indispensable to the full success of chemical improvements (manures) that the soil be first brought to those degrees of division, porosity, dryness, and depth, that are most favorable to vegetable growth. Besides rendering the soil so dry, warm, deep, and penetrable, that the plant finds a genial rooting place, these operations more or less facilitate the solution and elaboration of the food of the plant, since the soil is thereby divided, and more thoroughly subjected to the action of water and air.—*Theory of Manuring*. When the soil is deficient in those ingredients which favor the growth of the plant, the deficiencies may be supplied by manures. The principles on which manuring depends are the following: 1. Plants require various kinds of solid mineral matters, and derive the same exclusively from the soil. 2. Some plants which in the natural state derive the gaseous elements of their organic structure, viz., carbon, hydrogen, nitrogen, and oxygen, from the atmosphere, must be supplied with more or less of these matters from the soil, in agricultural production. 3. Different plants require different proportions of these substances in order to luxuriant growth. 4. Different plants require different quantities of these substances to mature a full crop. 5. Different plants, from peculiarities of structure, draw differently on the same stores of nutriment. 6. Different soils abound or are deficient, to a greater or less degree, in one or many needful ingredients of the plant. 7. The same soil has a different composition in different years, caused by the removal of matters in the crops, or by the increase of available food from weathering (tillage). The substances usually classed together as manures may have three distinct functions: 1st. They may chiefly serve to improve the physical characters of the soil. Such are some manures that are applied in large quantity, as lime, marl, and organic matters. 2d. They may act partly as solvents or absorbents, and thus indirectly supply the plant with food; *e. g.*, lime, gypsum, salts of ammonia. 3d. Finally, they may enter the plant as direct nutrition. If manures acted merely as direct nutrition, it would be possible to judge of the manuring value of any substance by comparing its composition with that of the ashes of cultivated plants; but since many fertilizers produce all the above-mentioned effects, the question becomes a more complicated one. Notwithstanding the facts which practice has accumulated concerning the action of a great variety of fertilizing substances, and the close scientific study of their effects, we are yet in

the infancy of our knowledge respecting them. In agricultural periodicals are reports of thousands of experiments on the value of manures; we find, however, the most conflicting statements, and a chaos of results. There are instances of nearly every proposed fertilizer increasing crops, and as many instances of failure. Farmers, however, continue to experiment as if there were a possibility of proving that for each kind of crop, or each variety of soil, there is a specific and unfailing fertilizer. The principles above stated, taken together with the fact that the physical adaptation of soils to crops is indefinitely varied and constantly changing, demonstrate that there can be no fertilizing panacea. They likewise make evident that what is this year a good application for a certain crop and soil, may have no action next year; and that what is now inefficacious, may prove highly useful at some future time. The most generally useful manures are those which contain the largest number of ingredients, and present them in the greatest variety of forms. Stable manure occupies the first rank among fertilizers, because it contains everything that is needful for the nutrition of plants. It is in fact the *débris* of a previous vegetation, and contains all the ingredients of plants, though in proportions altered from the original ones, and, indeed, advantageously altered. The hay, roots, and grain which mature cattle receive every day as food, are in part digested and assimilated; but since full-grown animals do not increase in weight, unless fattened, they excrete daily as much as they ingest. The most combustible portions of their food are, in consequence of the respiratory process, exhaled as water and carbonic acid gas; while the ash ingredients, and the larger share of the nitrogen, are accumulated in the excreta. In this way there is a concentration of constituents which, after they have served the nutritive function for the animal, become the proper food of the plant. Among the various ingredients of manures, two in particular have acquired a special significance in late years, viz., phosphoric acid and ammonia. These bodies are commercially the most valuable of all fertilizing substances, a necessary result of their scarcity; and in general, phosphoric acid is a smaller ingredient of cultivated soils than any other of the components of the ash of plants. Ammonia, especially in the form of carbonate, not only powerfully stimulates vegetable growth, but it probably exerts a strong solvent effect on the minerals which compose the soil. Hence, guano and other animal manures which contain or yield much ammonia and phosphoric acid, are in such large demand among those who practise "high farming." But the exclusive use of fertilizers which supply to vegetation only a small portion of its ash ingredients, must sooner or later be found inadequate to produce profitable returns; must, in fact, reduce the soil to a minimum of fertility. The true system of manuring is to main-

tain in excess a supply of all forms of plant food, and indeed of all materials which experience proves to have a good effect on vegetation, whether this effect be chemical or physical.—When chemical analysis first demonstrated that different classes of plants yield an ash of different composition, the idea of special manures had its origin. By special manures were meant mixtures containing just the quantity of each ash ingredient removed from the soil by an average yield of each crop. But investigation has demonstrated that there are in general no practical advantages in these attempts to feed the plant by ration. Lawes and Gilbert, of Rothamstead, England, believed they had established by a multitude of field experiments that ammonia is specially suited to the production of wheat, and phosphoric acid to the growth of turnips; but there are other authentic trials which as fully prove just the reverse. While on a certain soil, and under a certain set of circumstances, experience may without difficulty establish a rule, science is not yet far enough advanced to lay down a universally applicable principle concerning the special nutrition of the various classes of cultivated plants.—*Rotation of Crops.* The greatest return from the soil is generally secured, not by continuously growing one plant, even though it command the highest market price, but by an alternation or rotation of crops. There is no difficulty in cultivating any agricultural plant successively for any number of years on the same ground, provided enough be expended in putting the soil into the right physical and chemical condition. But such a procedure is usually more expensive than alternating the crops. When a light virgin soil comes under the hand of the farmer, it yields good crops for a few years, but then falls to a low state of productiveness. At first it may have yielded wheat; when no longer able to support that crop, it may still give fair crops of barley; the next year, if put to turnips or potatoes, it may seem to recover its fertility somewhat, and produce a good burden of roots; but now it will not yield again a good crop of wheat, though probably clover would flourish on it. The causes of such facts lie partly in the soil, and partly in the plants themselves. As for the soil, as already stated, its composition and texture are perpetually changing. The quantity of organic matter, especially, rapidly diminishes when the soil is under cultivation, and the soluble mineral matters are in most cases removed by cropping faster than they are supplied by weathering or disintegration. Practical men have classed cultivated plants according to their demands on the soil, as follows: Enriching crops, clover, lucern, and esparsette; non-exhausting crops, peas and beans, also cereals when cut green; exhausting crops, cereals, beets, turnips, carrots, and potatoes; very exhausting crops, tobacco, flax, hemp, and hops. Among the causes of the different exhaustive effect of various plants are

the following: 1. Different extent or structure of roots and leaves. The enriching crops expose to the air an enormous surface of foliage, and throw out very large, long, and numerous roots. The cereals have much less leaf and root surface. 2. Different rapidity of growth. Clover and root crops continue in foliage during the whole season, while the cereals ripen in July or August. 3. Periods or crises of growth; seed production. Plants which ripen seed require a better soil than those which only produce foliage, because the rapidity of assimilation seems to increase when the reproductive function comes into activity. Plants which ripen seed may require a richer soil, not because they remove more from it, but because they need more in a given time. 4. Some crops are entirely removed from the soil, as flax; while others leave the ground filled with an enormous mass of roots, as clover, or strewn with stalks and foliage, as the potato and beet. 5. The quantity of ash ingredients removed from the soil by different plants is widely unlike. In the light of the above statements, it is easy to see that when a soil refuses to yield remunerative crops of shallow-rooted and quick-growing wheat, it may still produce a luxuriant growth of deep-rooted, large-leaved, and slow-growing clover. It is evident, too, that when a clover ley is broken up and sown to wheat, this grain may yield well, because the decaying turf and roots are a ready source of every kind of plant food. This preparation of the soil for an exhausting crop, by the intervention of one of easy growth, is shown in the practice of green manuring, which is in fact a rotation of crops, but is also a fertilizing process, because the first crop is entirely sacrificed for the sake of the succeeding ones. Green manuring consists in ploughing under clover, buckwheat, spurry, or other crops, when in blossom, so that the soil shall be enriched by their decay. As these plants (the last named especially) will grow on poor soils, it is possible by their help to reclaim the lightest sands, and bring them up to a fair degree of productiveness in the course of a few years.—*Composition of Crops, and their Value as Food.* There are definite and unalterable relations between the character and habits of the animal and the composition and physical qualities of its food. In rearing and sustaining domestic animals, four distinct conditions occur, viz.: growth, or general development; fattening, or increase of flesh and fat; yielding milk; and performing labor. Different species of animals possess different degrees of aptitude in turning their food into one or other of these directions. Thus, the hog fattens most readily, the cow yields most milk, and the horse performs the greatest amount of labor. All these animals might be fed alike on a certain diet, and yet manifest their characteristic tendencies in a good degree, for the functions of all animals are the same to a certain point. That food, however, which best develops fat in the hog,

is not best adapted to sustain the labor of the horse. Where the animal's functions are required to differ in their essential nature, there the food must also differ; and we cannot carry the peculiar aptitude of an animal to the highest pitch without particular attention to the quality of the food. In fact, by a careful selection of the food we can change the character of the animal; and when at the same time other physiological circumstances, climate, &c., are suitably regulated, it is possible in the course of a few generations to impress new characters on a race. In this way the various breeds of cattle, swine, &c., have originated. A thorough understanding of the reciprocal relations between food and functional development is therefore of the highest consequence to the practical agriculturist. It cannot be pretended that science in its present state furnishes very extensive or satisfactory knowledge on these points. But physiological chemistry has developed some truths which warrant the hope of progress in this direction. The study of changes in the animal body has shown that there are two chief processes concerned in the maintenance of life, viz., nutrition and respiration. We use the word nutrition in a somewhat qualified sense, understanding by it the support of the working parts of the animal—the muscular, nervous, and cartilaginous tissues. These tissues contain nitrogen as an invariable ingredient, and for their development nitrogenous food, or food containing albumen, caseine, and fibrine, is indispensable. No work can be done on food consisting exclusively of starch, sugar, and oil, because these bodies cannot supply the nitrogen which is required for the organization of the working tissues. In the normal growth of active animals, the non-nitrogenous principles of the food are consumed in the respiratory process. These bodies are brought into contact with the oxygen inhaled by the lungs, and are burned into carbonic acid and water, which pass off in the expired breath. The heat of the animal is sustained by this combustion. In sluggish animals which ingest large quantities of non-nitrogenous food, the excess accumulates in their bodies in the form of fat. Great activity and full respiration are incompatible with this accumulation. The application of these facts is obvious. To keep a horse or an ox in working condition, we give a food rich in nitrogen, as oats; to fatten an animal, we use a food richer in starch, sugar, and oil. Experiments have been made with a view to determine what should be the relation between the nitrogenous and non-nitrogenous elements of the food for working, fattening, and milk-giving animals, as well as for otherwise determining the statics of nutrition. In Saxony much attention has been devoted to these subjects, and experiments in feeding, conducted in that country, have shown that breeding and dairy cattle thrive best when each animal receives daily for every 100 lbs. of its live weight

2.5 to 2.8 lbs. of food (calculated in the dry state), which contains 0.25 to 0.30 lb. of nitrogenous or nutritive, and 1.25 to 1.40 lb. of non-nitrogenous or respiratory, fat-forming material. The stomachs of cattle are adapted for a food containing a large quantity of woody fibre, which is mostly indigestible, and seems to perform a merely mechanical function in exciting the digestive apparatus. In the trials just alluded to, the best proportion of woody fibre was found to be one fifth of the whole dry matter. Years ago attempts were made to construct from chemical analyses tables of nutritive equivalents, for exhibiting the comparative value of different sorts of food. The first essays of this kind were very crude. Later results more nearly accord with experience, being founded on more complete analyses, and with a better knowledge of the wants of the animal; but there are many circumstances whose effect on the nourishing capacity of the different kinds of food has not yet been thoroughly studied. It has been proved that the use of nitrogenous manures increases the relative as well as absolute quantity of blood-forming substances in the grain. The digestibility and consequent nutritive effect of the grasses is greatest when they are cut just after attaining full flower, or, at any rate, before the seeds have hardened, as at this period they contain the maximum of soluble matters. Afterward the quantity of woody fibre increases. The cereals yield more and better flour when cut while the berry is still in the milk, and for a similar reason. The use of cooked food for cattle depends upon the fact that the cooking of food by boiling or steaming is equivalent to the preliminary processes of digestion; as in both cases cellulose, starch, dextrine, and the gums are progressively converted into grape sugar.—Toward the end of the last century the vague and ancient notions that air, water, oil, and salt formed the nutrition of plants, began to be modified with some truer ideas. In 1761 Wallerius, a Swede, in his treatise *Fundamenta Agriculturae Chemica*, recognized to some extent the connection between the composition of the ash of plants and that of the soil. Bergman, the great Swedish chemist, Pallas, and Réaumur also sought to study the chemical conditions of vegetable growth. In 1802 Sir Humphry Davy was invited to lecture before the English board of agriculture, and thereafter made numerous important observations. He recognized the fertilizing effects of ammonia, and analyzed numerous manures, including guano. About the same time Sennebier and De Saussure laid the foundations of vegetable physiology, demonstrated the assimilation of carbonic acid and water from the air, and indicated atmospheric ammonia as the probable source of nitrogen to the plant. De Saussure also fully recognized the nature, importance, and source of the ingredients of the ash, and studied the life of the plant in all its phases. In 1832 Sprengel made numerous

analyses of the ash of plants and of soils, employing more perfect methods than had been previously known. It was reserved for the splendid genius of Liebig to unite the fragments of truth into an organic whole. The force of his rhetoric, not less than of his logic, excited intense interest in the chemistry of agriculture; and being the most popular teacher that this science has ever employed, he has contributed vastly to the enlistment of laborers in this important field. While Liebig discussed only "the applications of chemistry to agriculture and physiology," his celebrated work under that title having been written at the request of the British association for the advancement of science, Boussingault, a Frenchman of genius and wealth, occupied himself with the special study of the practical operations of agriculture, and in 1842 issued his *Economie rurale*, a mine of valuable observations and experimental results. From that time on, the number of those devoted to the study of agriculture has rapidly increased.

AGRICULTURE, the art of cultivating the ground, and of obtaining from it the products necessary for the support of animal life. The change from a state of nature, in which the human race must have first lived, to the pastoral, or to any higher mode of living, must have been gradual, the work perhaps of ages. The race was doomed to toil, and necessity soon sharpened the power of invention. In the course of time, during which man multiplied and wandered about from place to place, the countries watered by the Euphrates, the Tigris, and the Nile were found to be most productive, and the dwellers in their valleys engaged in tilling the soil; while the dwellers in the hilly countries of Syria and the lands east of the Mediterranean, which were better adapted to grazing, became the owners of flocks and cattle. The chief riches of the early Jewish patriarchs consisted of cattle and fruits. Chaldea and Egypt, from the remotest recorded times, were noted as the lands of corn. The fertility of the valley of the Nile, a strip of country from 7 to 8 miles in width, gradually sloping down to the river, and extending from 400 to 500 miles, is well known. It was overflowed from about the beginning of August to the end of October, and the subsiding waters left the richest possible top-dressing of slime and mud. Then the cultivator had only to cast the seed, turn on a herd of swine to tread it in, and await the harvest. The agriculture of a people must be influenced by the climate and natural features of the country. Its progress must also depend in a great degree on the density of the population. The processes employed must have been extremely simple at first, being confined without doubt to merely preparing the ground for seed, without any attempt to stimulate its productiveness. So far as we know, Egypt, Chaldea, and China were among the first nations which extended the limits of agricultural practice in ancient times. In these countries, probably, ani-

mal power was first applied to agriculture; and among the hieroglyphics on the ancient tombs of Egypt is found the representation of an implement resembling a pick, which was used as a plough. From Egypt a knowledge of agriculture extended to Greece, and we find it in a tolerably flourishing state 1,000 years before Christ, if we may believe the testimony of Hesiod, who describes a plough consisting of a beam, a share, and handles. We may infer that the early settlers of Sparta possessed a knowledge of draining, since the site of the city was surrounded by swamps and marshes, and must have been well drained before it could be made even habitable. In Greece the art of farming gradually advanced, until in the days of her glory it may be said to have attained in some provinces a high degree of perfection. The Greeks had fine breeds of cattle, horses, sheep, and swine; many of the implements of husbandry in use among them were not very unlike in principle those of modern construction; and extensive importations were made from foreign countries of sheep, swine, and poultry, for the purpose of improving the stock. The use and value of manures were known also. The Greek farmers composted with skill, and saved the materials for the compost with care. The importance of a thorough tillage was well understood by them; they ploughed three times with mules and oxen, and sometimes subsoiled, and often mixed different soils, as sand and clay; they cultivated the apple, pear, cherry, plum, quince, peach, nectarine, and other varieties, together with figs, lemons, and many other fruits suited to the climate. The names of several of their agricultural writers have come down to us, though the works of only a few of them are extant, and of these the treatise of Xenophon is the most valuable. But, in comparison with many other countries, Greece was not well fitted for tillage. Agriculture was not a source of pride with the Greeks, as it afterward became with the Romans. One cause of this was the fact that the land was tilled mainly by a subdued and menial race, the dominant race cultivating other arts, and caring more for building up their cities than for cultivating the soil. On the contrary, a high appreciation of agriculture seems to have been a fundamental idea among the early Romans. A tract of land was allotted to every citizen by the state itself, and each one was carefully restricted to the quantity granted. It was said by the orator Curius, that "he was not to be counted a good citizen, but rather a dangerous man to the state, who could not content himself with seven acres of land." The Roman acre being about one third less than ours, the law actually limited the possession to about five acres. This, however, was only in the early days of Rome, and afterward, as the nation became more powerful, and extended its limits by conquest, the citizen was allowed to hold 50 acres, and still later he could be the holder of 500. The limitation of the freehold

in the earlier history of the nation, in connection with the old Roman love of agriculture, led to a careful and exact mode of culture, probably with the spade, and hence large and abundant crops were obtained. No greater praise could be bestowed upon an ancient Roman than to give him the name of a good husbandman. Cincinnatus was called from the plough to fight the battles of his country, and Cato the censor, distinguished as an orator, a general, and a statesman, is most loudly commended for having written a book on farming. The Roman senate ordered the 28 books of Mago, the most voluminous writer on agriculture in Carthage, to be translated into Latin for the use of the Roman people. Rome had in later times, including a century previous to the Christian era, an agricultural literature unsurpassed by that of any other country, ancient or modern, with the exception perhaps of Germany, France, and England of the present day. The works of her best writers, or such of them at least as have been transmitted to us, abound in sound maxims. "Our ancestors," says Cato, "regarded it as a grand point of husbandry not to have too much land in one farm, for they considered that more profit came by holding little and tilling it well." And Virgil says: "The farmer may praise large estates, but let him cultivate a small one." Speaking of the planting of trees as a means of protecting fields from high winds and storms, Pliny says: "Men should plant while young, and not build till their fields are planted; and even then they should take time to consider, and not be in too great haste. It is best, as the proverb says, to profit by the folly of others." The Roman farmers also paid much attention to the breeding of stock. Columella mentions the points of a good milch cow to be "a tall make, long, with very large belly, very broad head, eyes black and open, horns graceful, smooth, and black, ears hairy, jaws straight, dewlap and tail very large, hoofs and legs moderate." The same writer prescribes a curious treatment of working oxen, as follows: "After oxen get through ploughing, and come home heated and tired, they must have a little wine poured down their throats, and, after being fed a little, be led out to drink; and if they will not drink, the boy must whistle to make them." The Roman agriculturists whose works have come down to us are Cato, Varro, Virgil, Columella, Pliny, and Palladius. But there were obstacles in the nature and constitution of Roman society which made it impossible for the agriculture of Rome to reach a very high development. In the earlier days of the state, as we have seen, it was honored, but then the nation was in its infancy, extremely rude, and with a small population and a small territory. It was a time, too, when commerce was looked upon as degrading, and war and agriculture engaged the whole attention of the Roman citizen, the farmer thinking himself able both to till and to defend his little farm. As the empire grew in

power and wealth, the operations of agriculture were intrusted mainly to the hands of bondmen, who had little or no interest in the soil they tilled, and this alone was sufficient to prevent the art from reaching its most perfect condition. This imperfect cultivation was, without doubt, characteristic of the agriculture of Italy to some extent during the whole history of the Roman empire. We have, however, the statements of many successful crops, which show the interest manifested by individuals in different places. Thus Pliny says that 400 stalks of wheat, all grown from one seed, were sent to the emperor Augustus; and at another time 340 from one seed were sent to the emperor Nero from Byzacium in Africa, accompanied by the statement that "the soil when dry was so stiff that the strongest oxen could not plough it, but after a rain I have seen it opened by a share drawn by a wretched ass on the one side and an old woman on the other." As time passed on, improvements were made in the plough and other agricultural implements. The Roman plough, the exact model of which is still used in Italy, the south of France, and part of Spain, consisted of a beam to which the yoke was attached, a handle or cross piece by which the ploughman held a share fixed into a share beam, two mould boards or one at pleasure, a coulter, and sometimes a wheel, which could be used or not at will. There were ploughs for heavy soils and ploughs for light ones, and indeed nearly every variety, so far as the principles of construction were concerned, which is known at the present day. The Romans also used spades, hoes, harrows, rakes, and some other farm implements. With all these, however, the farmer's work advanced but slowly. The first ploughing required two days for a *jugerum* ($\frac{2}{3}$ of an acre), and the second one day. The difference of soils and their adaptation to particular crops were well understood. Manures were saved with care. The excrements of birds were especially valued, and judiciously applied; composts were made in suitable places, hollows being scraped out in the form of a bowl to receive the wash from the house, and properly protected from the heat of the sun; lupines and clover were sown to plough in green, and the grain stubbles were often burnt over for the sake of the ashes. With these appliances they raised wheat, rye, barley, oats, flax, millet, pease, beans, turnips, the grape, and the olive. But perhaps the ancients suffered more inconvenience in their agricultural operations from their failure to apply the mechanical forces of nature as a substitute for hard labor, than from any other cause. Even the water wheel was not known till more than 100 years after Christ, and the wind swept over the hills of Europe till the 11th century without turning a single mill. With the exception of some casual allusions by Roman writers, we have no accounts of the agriculture of other nations at or before the time when the Roman empire had begun to

decline. But there is every reason to suppose that the art had reached a greater degree of perfection in countries east of the Mediterranean and in Egypt, than in Italy. It is certain that the inhabitants of the East were familiar with many mechanical appliances unknown to the Romans, and probably their agricultural systems were more complete. Rome herself, in the later days of her greatness, was supplied to a certain extent with the agricultural products of her conquered provinces. Then set in that vast tide of conquest from the north, pouring over Italy, France, and Spain a race of barbarians, who gradually became absolute masters of nearly every country into which they penetrated. Agriculture was extremely depressed, and the condition of the serf to whom the tillage of the soil was left was in some cases even more hopeless and pitiable than that of the Roman slave who had tilled the soil before him. Scarcely a gleam of sunshine in the shape of improved culture lights up the gloom of this period, with the important exception of the introduction of an extensive system of irrigation in Spain, under the Saracens. These eastern invaders from the well-watered lands of western Asia and Egypt established in the peninsula what has been termed the southern system of agriculture, in distinction from the more peculiarly northern system of drainage, and developed the agricultural resources of Spain to an extent wholly unparalleled at that time in Europe, building reservoirs, canals, and aqueducts with immense labor and skill, and raising the annual revenues of that part of Spain under their dominion to nearly \$30,000,000—"a sum," as Gibbon says, "which in the 10th century probably surpassed the united revenues of all the Christian monarchs." The traces of these gigantic works still remain. Bruges and Ghent were important manufacturing and commercial towns as early as the 11th century, and agriculture and manufactures there grew up together, even before a large part of Europe had risen from a state of barbarism; but the agriculture of Belgium and Holland was long in attaining the perfection to which it has now arrived. In Britain, the Romans had made many alterations for the better during their 400 years of occupation, as they were accustomed to do in all their provinces; but the agriculture of the island was extremely rude even when they left it, by far the greater part being covered with forests and marshes. Then the Saxons overran the country, subsisting mainly by the chase and by keeping large numbers of cattle, sheep, and especially swine, which readily fattened on the mast of the oak and the beech. In general, the only grains raised were wheat, barley, and oats, and they had but small quantities of these. The results of their labor were so uncertain and insecure, on account of the inability of the government to protect property and life, that all attempts at improved agriculture would have been in

vain, even if individuals had been disposed to engage in them. The suffering among the people was often intense, famines frequently occurred, and so little was done to furnish suitable winter food and shelter for the stock, that a large part of the cattle perished every winter, especially in the more northerly parts of the island. The proportion thus dying annually has been estimated at one fifth of the whole number in the country, while frequently the most terrible murrain swept off a far larger proportion. No hoed crops or edible vegetables were cultivated, and even as late as the reign of Henry VIII. Queen Catharine was obliged to send to Flanders or Holland for salad to supply her table. Neither Indian corn, nor potatoes, nor squashes, nor carrots, nor cabbages, nor turnips were known in England till after the beginning of the 16th century. The peasants subsisted chiefly upon bread made of barley, ground in the quern or hand mill, and baked by themselves. The tenant peasantry had no security for their property till after the middle of the 15th century. If the estate was sold by the landlord, they were obliged to quit all, giving up even their standing crops without compensation. They were liable for the debts of the landlord to an amount equal to their whole property, and it was not till after that time that they were held only for the amount of rent due from them. This picture of the misery and suffering which prevailed in Britain will give a fair idea of the state of things in Europe generally at the same time. Rather more attention, however, was paid to the culture of the soil in the religious establishments, whose tenancy was more secure. Under the direction of the monks extensive improvements were made in draining swamps and reclaiming extensive tracts from the sea. The feudal system, introduced into England soon after the Norman conquest in the latter part of the 11th century, checked progress in agricultural improvement. The crusades elevated the condition of the peasant in some degree, by increasing the value and importance of his labor, by making the acquisition of land somewhat easier, and by withdrawing from the country many ignorant and despotic nobles, some of whom returned with a profitable recollection of the far higher culture and fertility of the East. But the agriculture of this whole period was generally as low as was possible in an age making any pretension to civilization.—We may fix upon the 16th century as the time when Europe awoke from its long slumber. From that time to the present, the gradual elevation of the middle and lower classes has continued, and agriculture has steadily advanced. The first work on agriculture published in England was the "Boke of Husbandrie," in 1523, by Sir Anthony Fitzherbert, who styles himself "a farmer of 40 years' standing." This was followed by another volume by the same author on land surveying. In these works Fitzherbert points out the prevailing practices of

his time, condemning some and approving others. "A housebande cannot thryve," says he, "by his corne without cattell, nor by his cattell without corne;" and he adds, "Shepe, in myne opinion, is the most profitable cattell that any man can have." From him it appears that marl was in common use in his day, as it had been in the island even when it was invaded by the Romans before the Christian era. Thomas Tusser's "Five Hundred Points of Good Husbandry," in a sort of doggerel verse, followed a quarter of a century later, and went through many editions. The editor of one published in 1812 says that he found difficulty in procuring a complete copy, "a proof that what was intended for practical use had been sedulously applied to that purpose. The copies were passed from father to son, till they crumbled away in the bare shifting of the pages, and the mouldering relic only lost its value by the casual mutilation of time." Tusser mentions carrots, cabbages, and turnips, as having just been introduced as kitchen vegetables. Then appeared "The Whole Art of Husbandry," by Barnaby Googe; "The Jewel House of Art and Nature," by Sir Hugh Platt, from whom we first hear of the introduction of white clover into cultivation in England; and in 1649 appeared the "English Improver" of Walter Blithe (afterward revised and called the "Improver Improved"), a work full of judicious maxims and sound advice, giving us an insight into the prevailing practices of that time. Sir Richard Weston wrote about the same time on the husbandry of Brabant and Flanders, under the name of Samuel Hartlib, who himself made important contributions to agricultural literature. But the experiments and writings of Jethro Tull, in the early part of the 18th century, are among the first important attempts at real progress in the agriculture of modern times. Writers before his time had confined themselves mainly to plain statements of the practical details of farming, recommending such new practices as appeared to them worthy of adoption, and condemning the errors of their contemporaries. Tull struck out new paths of practice, invented new modes of culture, and his investigations into the principles of fertility fairly entitle him to the credit of being a great original discoverer, though the errors into which he fell in his zealous enthusiasm brought more or less temporary discredit upon his whole theory. But we can excuse his mistakes when we consider that he, like all his predecessors, was groping in the dark, before chemistry and geology had made known the elements of the soil and of plants, and shown how the latter derive their support and nourishment. Tull invented and introduced the horse hoe and drill husbandry. The latter had, indeed, been known previously in Spain, and according to some in Germany also, but it was not known to any extent in England. He also invented the threshing machine, though the flail was almost universally used in England

till the close of the last century. His doctrine that plants derive their nourishment from minute particles of soil, and that repeated and thorough pulverization is therefore necessary not only as a preliminary preparation, but during the growth of the plant, led directly to the practice of drilling grain crops, and the awkwardness and prejudice of his workmen led to the introduction of the drilling machine and the horse hoe as substitutes for hand labor. So far Tull was right in practice, however incorrect his theory may have been. The best practical farmers of the present day believe in frequent, deep, and thorough pulverization of the soil, not because the plant is supposed to live on minute particles of earth, but to admit air and moisture freely to the roots. Tull's theory of the nutrition of plants has not been without its followers, however, Dubamel himself having labored to spread it. Tull believed to some extent in the use of manures, but chiefly as dividers of the soil, as a means of improving its physical texture, and not because he supposed them to furnish any nutriment to the plants themselves. His system of husbandry found very few followers at first, and those who adopted it were in many cases obliged to return to the old methods, for want of the necessary mechanical instruments for following his directions; but it has been more recently revived, mechanical skill making it practicable and comparatively easy of application, while thorough drainage, trenching, and subsoil ploughing have gained the assent of most intelligent farmers. Even his drilling system for wheat and other grain crops has been extensively adopted in Great Britain, and is fast gaining favor. After Tull, we find little progress in agricultural literature till toward the close of the last century. The chief gain in the art in the intermediate time was occasioned by an active competition in cattle breeding by Bakewell and others in England, which led to the most important practical results. Arthur Young, to whom perhaps the world is more indebted for the spread of agricultural knowledge than to any other man, was born in 1741, and died in 1820. His journeys to obtain information on agricultural subjects, and his writings, had a powerful influence in creating a love for agricultural pursuits among the learned. His searching inquiries and experiments on different soils, to ascertain the real causes of fertility (1783-'6), laid the foundation at least for more exact researches into the principles of fertility afterward. He first established the fact that common salt is a valuable manure, though it had been recommended before his day. Previous to his time ammonia was thought to be injurious to vegetation, and natural philosophers had asserted that the food of plants was contained in acids. Young tried it in very many cases, and always with great success. He made experiments to learn the effect of the sun's rays on the soil, and came to the conclusion "that covering the soil is beneficial to it."

Hence we may infer the error of the ancient practice of summer fallowing, which left the ground wholly unoccupied with crops every second or third year; a practice which continued in England down to a comparatively recent period, and even now prevails in many parts of Europe. He found that nitrogenous manures increased the power of plants to avail themselves of mineral manures, thus showing the advantage of a proper use of both classes, a conclusion whose truth has been still more recently established by Lawes and others. He also tried the effect of different gases on vegetation. In 1786 he says: "To imagine that we are ever to see agriculture rest on a scientific basis, regulated by just and accurately drawn principles, without the chemical qualities of soils and manures being well understood, is a childish and ignorant supposition." Such were some of the efforts of Arthur Young; they may be found embodied in the "Annals of Agriculture," and other useful treatises. But one of the first systematic works on the subject, which can be said to have really advanced the art of agriculture, was the "Practical Agriculture, or Complete System of Modern Husbandry," by R. W. Dickson (1805), which Thier, who had it translated and published in Berlin in 1807, calls the first truly scientific work of the English, not even excepting Young's writings. Dickson's chief merit, however, is his excellent collection of the many valuable experiments and statements of distinguished members of the board of agriculture, and other farmers. In the period embracing the close of the last century and the beginning of the present, we find many important additions to the literature of agriculture. Such are the works of Marshall; the admirable works of Young already alluded to; Elkington's "Mode of Draining Land," described by Johnstone; "Davison's Phytology," "Modern Agriculture," and "Synopsis of Husbandry," by Donaldson; the "Gentleman Farmer," by Lord Kames; "Anderson's Essays"; the "Communications to the Board of Agriculture," and numerous agricultural reports. "The Experienced Farmer" and many others might be mentioned, all of which contributed more or less to awaken the spirit of inquiry and improvement which has eminently characterized English agriculture for the last 50 years, and made it a model for the rest of the world. Nor has the agriculture of Scotland felt the influence of the spirit of progress in a less degree. In 1768 Lord Kames, in the "Gentleman Farmer," very forcibly described its imperfect condition at that time. He says: "Our draught horses are miserable creatures, without strength or mettle; our oxen scarcely able to support their own weight, and two going in a plough, led on by two horses; the ridges in the fields high and broad, in fact, enormous masses of accumulated earth, that could not admit of cross ploughing or cultivation; shallow ploughing universal; ribbing,

by which half the land was left untilled, a general practice over the greater part of Scotland; a continual struggle between corn and weeds for superiority; the roller almost unknown; no harrowing before sowing, and the seed sown into rough, uneven ground, where the half of it was buried; no branch of husbandry less understood than manure; potatoes generally planted in lazy beds; swine but little attended to; and very few farms in Scotland proportioned to the skill and ability of the tenant!" "What a contrast," exclaims Sir John Sinclair, 40 years after, "to the present state of Scotch husbandry; and it is singular that, with hardly an exception, these imperfections have been removed. Had it not come from so high an authority, it is hardly possible to credit, that within the memory of so many persons now living our agriculture could have been so miserably deficient as it seems to have been at that time." But in the course of these 40 years the Scotch farmers had acquired a habit of reading, and agricultural books were extensively distributed among them. Besides this, many of them visited other countries for the purpose of obtaining information, and observed the improved practices prevailing there, to return and introduce them at home. Sir John Sinclair was born in 1754, and died at Edinburgh in 1835. His writings were numerous and important. Hartlib, a century and a half before, and more recently Lord Kames in the "Gentleman Farmer," had pointed out the utility of a board of agriculture, but it was left to the zeal and untiring effort of Sir John Sinclair to call into life that valuable auxiliary to agricultural progress, and the board was created in 1793. To its establishment, more than to any other movement of that day, England is indebted for the present high and prosperous state of her agriculture. It brought men together from all parts of the kingdom, made them acquainted with each other's views, and with the modes of culture prevailing in sections of which they had previously been ignorant. It was through the encouragement of the board of agriculture chiefly that Sir Humphry Davy was led to investigate the elements of the soil, and to apply the science of chemistry to the improvement of agriculture. And here begins properly the real progress of the art; for without a knowledge of the simple substances of nature, agriculture could not be expected to attain the rank of a science. The lectures of Davy before the board of agriculture from 1802 to 1812, therefore, mark an important epoch in the history of modern agriculture. The substance of these lectures was embodied in his "Elements of Agricultural Chemistry," published in 1813, and translated into German in 1814, and into French in 1829. This work opened to the reflecting farmer new and interesting views of the principles of fertility and vegetation. Davy showed how plants, soils, and manures could be analyzed, and manures selected which would fur-

nish the elements needed by the different varieties of plants. We find him in 1807 trying to ascertain the effects of various salts on barley, grass, &c., in light, sandy soils, applying twice a week diluted solutions of sulphate, acetate, bicarbonate, and muriate of potash, sulphate of soda, and nitrate, muriate, sulphate, and carbonate of ammonia; finding, as Young had found, that plants furnished with carbonate of ammonia grew most luxuriantly, a result which had been anticipated from the composition of carbonate of ammonia. Davy experimented on specimens of guano sent to the board of agriculture in 1805, the existence of it in large quantities on the South sea islands having been pointed out by Alexander von Humboldt. In 1806 elaborate analyses of guano were published by Fourcroy and Vanquelin. Davy, writing at this time, says: "The dung of sea birds has never been used in this country." Davy recommended the use of bones as a manure, not so much because they contained phosphate of lime, as because they were filled with decomposable animal matter, as gelatine, cartilage, fat, &c. But though the results obtained by Davy were imperfect, and in some cases erroneous, they made important advances in an almost untrodden path of investigation. The facts established by his researches as to the effect of ammonia on vegetation, may be regarded as the starting point of modern scientific investigations into the properties of this substance when used as a manure; for, though Young first led the way in observing its practical effect on plants, his conclusions, from his want of chemical skill, had not the scientific certainty which characterized Davy's, and which was necessary to give them their highest value. It may indeed be said that he was the means of drawing the attention of chemists to this particular branch of their science; for through the influence of the reputation he gained, the thoughts of other scientific men, and especially of the chemists on the continent, were turned in this direction.—In general, the literature of agriculture had advanced more rapidly on the continent than in England. In Germany especially many writers had treated of the subject, more particularly in works on political economy. In the latter half of the last century many treatises of practical value appeared, such as those of Kretschmar, Reichart, Stisser, and Sprenger. At the same period Duhamel wrote in France, and adopted the views of Tull in regard to the nourishment of plants. In his treatise on the cultivation of the soil he endeavors to determine the principles of agriculture by theories deduced from experiments, which subsequently received a more scientific form in the "Elements of Agriculture," published in Paris in 1771. Duhamel, Buffon, and others, by their superior genius, made the study of rural economy attractive to scientific men in France; and hence there has been there more original research in agricultural chemistry, vegetable

physiology, and other kindred branches, than in any other country except Germany. As early as 1730 there were 13 agricultural societies in France, with about 19 auxiliary societies. The survey of France by Arthur Young, in 1787 and 1789, also did much to excite an interest in the improvement of the soil, and to make the peculiarities and wants of the country more familiarly known even to Frenchmen themselves. Merino sheep were brought into France in 1776, and kept under charge of the government for the improvement of the stock of the country. Bonaparte greatly increased the number of societies, established professorships, botanical gardens, &c., all of which concurred to elevate the study of agriculture in the estimation of those capable of bringing to its aid the principles of the abstract sciences; and this tendency has influenced the scientific minds of France to the present day, though the practice of the country has not kept pace with the development of theory. This is owing partly to the division of property since the revolution, the holdings, as a general thing, being very small.—The earliest settlers of the United States found the country a wilderness, with many varieties of climate and soil to which the knowledge they had obtained in the mother country did not apply. Thus they had to contend with innumerable obstacles, with the wildness of nature, and their ignorance of the climate, in addition to the hostility of the Indians, the depredations of wild beasts, the difficulty and expense of procuring seeds and farming implements, &c. These various difficulties are quite sufficient to explain the slow progress they made in the way of improvement. For many years agriculture was exceedingly backward. Stock and tools were poor, and there were obstacles and prejudices against any "innovations" in the established routine of practice. This state of things continued for many years, with very little change. Jared Eliot, a clergyman of Connecticut, one of the earliest agricultural writers of America, published the first of a series of valuable essays on field husbandry in 1747; but, with this and a few other exceptions, no real efforts were made to improve farming till after the revolution, when the more settled state of the country and the gradual increase of population began to impress the intrinsic importance of the subject upon the minds of a few enlightened men. The South Carolina agricultural society was established in 1784, and still exists; and the Philadelphia society for the improvement of agriculture, established in the same year, and a similar association in New York in 1791, incorporated in 1798, and the Massachusetts society for the promotion of agriculture established in 1792, were active in their field of labor, and all accomplished important results. The correspondence at this period between Sir John Sinclair and Washington shows how anxious was the father of his country to promote

the highest interests of the people by the improvement of agriculture. Many years elapsed before the habit of reading became sufficiently common among the masses of the actual tillers of the soil to justify an expectation of immediate profit from the annual publication of the transactions of the several societies. The improvements proposed fell dead upon the people, who rejected "book farming" as impertinent and useless, and knew as little of the chemistry of agriculture as of the problems of astronomy. All farm practices were merely traditional; no county or town agricultural societies existed to stimulate effort by competition. There were no journals devoted to the spread of agricultural knowledge. The stock of the farm was such as one might expect to find under such circumstances; the sheep were small and ill cared for in the winter, and the size of cattle generally was but little more than half the average of the present time. The value of manures was little regarded; the rotation of crops was scarcely thought of; the introduction even of new and labor-saving machinery was sternly resisted and ridiculed by the American farmers of that day, as well as by the English laborers. It was long before the horse rake was brought into use in opposition to the prejudices it encountered. It was equally long before the horse-power threshing machine was adopted. In some parishes of Great Britain, even so late as 1830, the laborers went about destroying every machine they could find. Within the last half century, chemistry, the indispensable handmaid of agriculture, has grown with great rapidity, and in each new discovery some new truth applicable to practical agriculture has come to light.—In the time of the Saxons, in England, as we have already seen, the plough was extremely rude. It was made by the ploughman himself, under the compulsion of a law forbidding any one to hold a plough who could not make one, or to drive until he could make the harness. The progress made previous to the time of Jethro Tull was comparatively slight, either in the manufacture of the plough, or in any other branch of agricultural mechanics. Tull, as we have seen, invented the horse hoe and the drilling machine. Both of these were then rude, but they have since been vastly improved in their details. The plough was generally made of wood till the beginning of the present century, but its form has since passed through many changes. It cannot yet be regarded as a perfect implement of its kind, but it has been fast approaching toward perfection of late years, and the mode of manufacture has improved to an equal extent. (See PLOUGH.) Nor has the improvement in other farm implements been less marked than in the plough. Spades and hoes are lighter and better constructed than formerly. The reaper and the mower have gained a firm footing even within the last 30 years. As labor and time-saving machines are now deemed indispensable by all

who raise grain and hay on a large scale, the reaper and the mower may be regarded as types of the present, as the sickle and the flail are types of the past. (See MOWING AND REAPING MACHINES.) Among the other labor-saving implements which are now generally introduced upon farms of any extent are the horse rake, the improved horse hoes, the seed and corn sowers, the broadcast seed sower, the improved subsoil and trenching ploughs, the straw and root cutters, the cultivators, the threshing and winnowing machines, and many others of equal importance. It is safe to say that the improvements in the implements named, made within the last half century, have enabled the farmers of the United States to accomplish at least double the amount of labor with the same number of teams and men. This is a grand and practical advance over all former periods in its history, and promises a future development of the resources of agriculture almost beyond the power of language to describe.—The progress which has been made in the application of chemistry to agriculture is hardly less gratifying. For though from year to year there may seem to be little progress, yet when we compare any two periods of five or ten years, the increase of practical knowledge derived from the investigations of the agricultural chemist, as well as its importance, is very perceptible. Since 1840, chiefly through the labors of Prof. Liebig, animal and mineral phosphates, superphosphate of lime, and other artificial manures have come to be very extensively employed; and it is only since the same date that guano, though known long before, has come into general use. (See AGRICULTURAL CHEMISTRY, BONE DUST, GUANO, &c.) An impartial survey will show that the actual production of the means of supporting life has largely increased, as the true principles of cultivation have become better known and understood. The average yield per acre of some of the cultivated grains, as wheat, for instance, has nearly quadrupled in countries where these principles have gained the strongest hold, even within the memory of men still living; and this increase is not merely proportionate to the greater number of producers, or the additional acres brought under tillage, but an absolute increase per acre. It is difficult to ascertain the amount of crops, or the average yield, of very distant times past, but the average yield per acre of wheat in the 11th century was estimated by the highest authority of that day, the author of "Fleta," at only 6 bushels. So 300 years later, in 1390, 57 acres on a farm at Hawsted yielded only 366 bushels, and on an average of three years little more than that. The actual productive power of Great Britain in the article of wheat alone increased during the half century from 1801 to 1851 to the extent of supporting an additional population of 7,000,000, an increase which can be ascribed with confidence mainly to improved cultivation. So in every country where agriculture

receives the attention it deserves, the productive power of the soil has largely increased. Even the Atlantic states of the Union, where the system of cultivating the soil without maintaining its fertility by a proper treatment prevailed for many years, are not an exception, since the condition of agriculture is rapidly improving in the oldest of them, where this system was earliest begun, and the general average of crops, with the exception of the potato, is increasing from year to year as a more proper culture is introduced and persevered in, the farmer being led to improve his practice by the pressure of an increasing population and constantly rising prices. In New England, for instance, one of the oldest sections, the general average yield of Indian corn per acre has risen to about 35 bushels, while crops of 50 and 60 bushels per acre are not uncommon, and 80 and 100 are sometimes obtained by careful tillage. The situation and soil of New England are not such as to make it what is called a wheat-growing region, and this fact, which farmers were long in understanding, has caused a great decrease in the extent of land devoted to this crop. Indian corn, root crops, and all the varieties of fruit suited to temperate latitudes, are found to be more certain and remunerative, and attention is given mainly to them. In the mean time the system of farm management is gradually improving, new implements to facilitate labor are introduced, and much greater care and economy than formerly in regard to manures everywhere prevail, most farmers having good barn cellars arranged for its preservation, into which peat and loam are carried in large quantities, and composted from time to time during the winter as absorbents and divisors. Societies have been established in all the states, and in most of the counties. In Massachusetts a department of agriculture is organized as a branch of the government, to collect, arrange, and systematize all the latest information on the subject for distribution among the people, and to superintend the development of the established policy of the state; and a bureau of agriculture has more recently been established by the national government, in the interior department. In the middle states societies are equally active in efforts to raise the standard of their agriculture, and have adopted a similar liberal policy, and in some, especially New York, a high degree of improvement has been reached. The western states are more strictly and exclusively agricultural than any other section of the country. Most of them publish annually, at the expense of their governments, valuable reports on practical agriculture for circulation among the people. Notwithstanding the immense amount already produced, however, the resources of the west have but just begun to be developed as they are destined to be hereafter. The southern states are also large producers of grain, but are mainly devoted to the raising of cotton and sugar, both of which are exported in large

quantities.—The present condition of practical agriculture in Great Britain has already been alluded to, as worthy of imitation in other countries of similar climate and soil. But the points in which progress is most distinctly seen are the extensive culture and use of root crops, the general system of thorough drainage, the introduction and use of new and improved implements of husbandry, and the breeding of stock. The land, unlike that of the United States, where as a general rule the farmer is the owner as well as the cultivator, is held chiefly in large estates, concentrated in the hands of a few individuals, and leased to the tenant farmer, who either tills it himself or sublets it to others. But few, therefore, of the actual tillers of the soil are owners of land. Associated effort has done much to awaken a lively interest in the subject, both among the nobility and the people. The royal agricultural society, established in 1839, with its ably conducted journal, the Highland agricultural society of Scotland, and the royal society of Ireland, are doing all in their power to develop the agricultural resources of the country. Many valuable agricultural journals are well supported and widely circulated. In France the tendency for many years has been to the division of landed estates, and comparatively few large holdings exist at the present time. Subdivision of property in the hands of small proprietors without capital prevents the development of practical agriculture; and in many of the departments its condition is still rude. The government has its minister of agriculture, and supports agricultural schools and veterinary establishments, while the "Journal of Practical Agriculture" and other agricultural periodicals are doing much to improve both the science and the practice of the country. With regard to the division of landed property, the same state of things prevails also in Belgium and Holland as in France, the agriculture of those countries being characterized rather as gardening than farming. The extreme care and economy of manures, and the careful application of liquid manures in these countries, are often referred to as worthy of imitation. In Germany, as already seen, the science of agriculture has been extensively developed, many of the ablest chemists having devoted their lives to this pursuit. Thaer, Schwercz, Köller, Stöckhardt, Liebig, and others, have a world-wide reputation. Here, also, as in most other countries, associated effort is made to advance the condition of agriculture.

AGRIGENTUM (called by the Greeks *Aeragas*; now *Girgenti*), an ancient Sicilian city, the rival of Syracuse, on a lofty eminence on the S. W. coast. It was settled by a Doric colony from Gela, about 580 B. C. During the 5th century B. C. it attained its highest prosperity, when its population was probably above 200,000. The city was celebrated for the beauty of its architecture, both public and private. Its greatest public edifices were the temples of

Concord and of the Olympian Jupiter, of which gigantic ruins remain. Shortly after its foundation it was ruled by the tyrant Phalaris, and in the following century by Theron (488 to 472).

Temple of Concord, Agrigentum.

It was repeatedly involved in hostilities with Carthage, and in 405 B. C. was razed to the ground by an army of that nation. It was rebuilt by Timoleon, and in 210 became permanently subject to Rome, growing to be one of the most prosperous of the cities of Sicily, with a great trade in corn, wine, and oil. The Saracens captured it in A. D. 825, and kept possession of it till 1086. (See GIGENTI.)

AGRIONIA, a yearly festival in honor of Bacchus Agrionius, anciently held at Orchomenus, Bœotia, exclusively by women and priests. The women would make a pretended search for the god, and finally desist, saying he had escaped to the muses. Then all would assemble at a repast, and amuse themselves by guessing riddles; whence collections of riddles, charades, &c., have been called "Agrionia." But the most remarkable part of the festival was the pursuit of a band of virgins by a priest with a drawn sword, who killed the one he caught as a sacrifice, in memory of the sacrifice of a boy by the daughters of Minyas in a Bacchic fury. In later times the killing was omitted.

AGRIPPA. **I.** Herodes. See **HEROD.** **II.** Marcus Vipsanius, a Roman general and statesman, born in 63 B. C., of an obscure family, died in March, 12 B. C. He was a schoolmate of Octavius (afterward Octavianus and Augustus), at Apollonia in Illyria, and was his chief instrument in establishing the empire. After the murder of Julius Cæsar, Agrippa accompanied Octavius to Rome, prosecuted Cassius, and received the oath of fidelity from the legions which had declared for Octavius. In 40 he took Perugia from Lucius Antonius after a long siege, and Sipontum from Mark Antony. In 38 he aided Octavianus by his victories in Gaul. In 37, after converting the Luerine lake into a harbor, he created a fleet, with which the next year he decisively defeated Sextus Pompey at Mylae and Nauloclus. In the subsequent war against Antony he also commanded the fleet, and

chiefly contributed to the great victory at Actium in 31. He accompanied Augustus to the war against the Cantabrians in Spain in 25; and in 19, being in command there, he entirely subdued them, after having in the same year pacified the Gauls, and constructed four great roads and the aqueduct at Nîmes. Agrippa was prætor in 41, consul (with Octavianus) in 37, 28, and 27, ædile in 33, and tribune from 18 till his death. During his ædileship he made great public improvements at his own expense, constructing and restoring aqueducts, erecting splendid buildings, &c.; and in his third consulship he built the Pantheon. In 16, after a journey to Jerusalem on the invitation of Herod the Great, he founded Berytus (Beirut). He died suddenly on his return from a successful mission to tranquillize Pannonia. Agrippa was married first to Pomponia, daughter of T. Pomponius Atticus; afterward (about 28) to Marcella, niece of Augustus; and in 21 to Julia, Augustus's daughter, Marcella having been divorced at the emperor's desire. His sons Caius and Lucius by Julia were adopted by Augustus, but they both died young. His posthumous son Agrippa was also adopted by Augustus, but was afterward banished for life to the island of Planasia on account of his savage disposition, and on the accession of Tiberius, A. D. 14, was put to death.

AGRIPPA VON NETTESHEIM, Heinrich Cornelius, a German philosopher, born at Cologne, Sept. 14, 1486, died at Grenoble, Feb. 18, 1535. He was a linguist, statesman, soldier, physician, theologian, and chemist. Having engaged in some peasant insurrections in the south of France, he retreated to Paris, where he held public discourses, and the reputation he thus acquired gained him a professorship of theology at Dôle. Accused of heresy, or more probably magic, he fled to England in 1510, whence, however, he returned to Cologne, and afterward became secretary of the emperor Maximilian. He fought in a campaign against the Venetians, and was knighted on the field. Tired of this employment, he applied himself to the study of physic, lectured publicly at Pavia, held an office in Metz, and then returned to Germany. At the invitation of Henry VIII. and Francis I., he visited both England and France. He was an ardent student of alchemy and the occult sciences, in reference to which he insisted that the writings of adepts were not to be read for a literal, but for a mystical meaning. His work *De Incertitudine et Vanitate Scientiarum* (Paris, 1531) is a satire on the state of knowledge at the period in which he lived.

AGRIPPINA. **I.** Youngest daughter of Agrippa and Julia, and wife of Germanicus, born before 12 B. C., died A. D. 33. She was a woman of great ability, beauty, and virtue. She accompanied Germanicus in his campaigns, and once, in his absence, took the command and saved the army by preventing the breaking down of a bridge over the Rhine in a panic. After the death of Germanicus in Asia she brought home

his ashes, and was met everywhere on the way with manifestations of sympathy and respect, and at Rome with unparalleled honors. But she was an object of hatred to the emperor Tiberius, and in A. D. 30 he banished her to the island of Pandataria, where she died, as is supposed, by voluntary starvation. She was the mother of nine children, one of whom was the emperor Caligula. Her sons Nero and Drusus fell victims to the tyranny of Tiberius and the jealousy of Sejanus. **II.** Daughter of the preceding, born at Cologne (hence called Colonia Agrippina) between A. D. 13 and 17, died in 59. She was gifted and beautiful, but is one of the vilest characters in history. She was first married to Cn. Domitius Ahenobarbus, and after his death to Crispus Passienus, whom she was accused of poisoning. Her brother Caligula banished her and her sister Drusilla to the island of Pontia in 39, but they were released by Claudius on his accession in 41. After the murder of Messalina she succeeded in inducing her uncle Claudius to marry her (49), the act being legalized by the senate, and to adopt her son Nero by Ahenobarbus as his successor, to the exclusion of his own son Britannicus. She then proceeded to remove all rivals and enemies by poison, and finally Claudius himself (54), his fate being hastened by an incautious threat uttered by him. After Nero's accession, having alienated him by domestic intrigues, she resorted to the most revolting means for regaining his affection; but her efforts failed, and she was assassinated by his orders in her villa on the Lucrine lake, after the failure of an attempt to drown her in a vessel purposely contrived to break to pieces at sea. She left commentaries on her own and her family's history, which were used by Tacitus.

AGUA (Sp., water), **Volcan de**, a mountain in Guatemala, Central America, 25 m. S. W. of the capital, New Guatemala. In form it is a graceful cone, its base extending over nearly all the western part of the valley of Guatemala. The traveller Stephens estimates its altitude at 14,450 feet above the level of the sea. Cultivated fields surround the base, and a belt of forest and verdure extends to the summit. The crater-like hollow on the top measures 140 by 120 yards. Its name is derived from the fact that occasionally torrents of cold water flow out of its northern side. The volcanic mountain of Pacaya lies to the S. E., and that of Guatemala to the N. W.

AGUADO, Alexandre Marie, a Parisian banker, born at Seville, June 29, 1784, died April 14, 1842. In early life he joined the Napoleonic party in Spain, held a commission in the French army, and fought for Napoleon up to the battle of Leipsic, when he quitted the army, engaged in trade and banking, and in 1823 was appointed banker for the Spanish government at Paris. He was created a Spanish marquis by Ferdinand VII., and received from Otho of Greece the order of the Redeemer. He lived in great

splendor, and died worth \$12,000,000. He had a gallery of very fine pictures, which were engraved and published as the *Galerie Aguado* (Paris, 1837-'42).

AGUAS CALIENTES. I. The smallest state of the Mexican republic, nearly enclosed by Zaca-tecas, and bounded S. by Jalisco; area, 2,946 sq. m.; pop. in 1868, 140,630. The eastern districts consist of elevated table lands, averaging 5,000 to 6,000 feet above the sea, and the western of broken mountain ranges, including the sierras of Laurel and Pinal, spurs of the Sierra Madre or Cordillera. The table lands produce abundant crops of cereals and a variety of fruits, of which olives, figs, grapes, and pears are the principal. There are a few unimportant silver and other mines within the state. It is divided into the four districts of Aguas Calientes; Rincon de Romos, Asientos, and Calvillo. **II.** The capital of the preceding state, situated upon a plain 6,000 feet above the sea, 270 N. W. of Mexico; pop. 22,534. It takes its name from two warm mineral springs in its neighborhood. The great road from Mexico to Durango and Sonora and that from San Luis Potosi to Guadalajara meet at Aguas Calientes. It is surrounded by rich gardens, abounding in olives, figs, vines, and pears, and contains churches, convents, and a hospital.

AGUE, a word denoting tremor, which has been used by medical writers in the sense of chill or rigor. Fever and ague is a popular name for intermittent fever. (See FEVERS.) Cases of intermittent fever, lacking the usual chill or cold stage, and in other respects latent, are sometimes distinguished as cases of "dumb ague." The name "ague cake" is applied to enlargement of the spleen occurring not very infrequently in the course of intermittent fever.

AGUESSEAU, Henri François d', a French jurist, born at Limoges, Nov. 27, 1668, died Feb. 9, 1751. In 1690, when only 22 years old, Louis XIV. appointed him advocate general, and in 1700 he became procureur general. He resisted the registration of the papal bull *Unigenitus*, on the ground that it encroached on the rights of the monarchy. In 1717 he was made chancellor by the regent Orleans. Almost alone he opposed Law's schemes for making the nation suddenly rich, and was dismissed, but recalled in 1720, on the bursting of the bubble. In 1722, Cardinal Dubois being appointed president of the council, D'Aguesseau retired, to be reappointed in 1737, finally resigning in 1750, at the age of 82. He endeavored to reduce the incongruous laws of France to uniformity, had an extensive acquaintance with literature, and was versed in many European languages. His writings have been published in several editions, the most complete in 16 vols. 8vo (Paris, 1819-'20); and his *Lettres inédites* appeared in 1823 (2 vols. 8vo).

AGUILAR, or **Aguilar de la Frontera**, a town of Spain, in the province and 22 m. S. by E. of Cordova, on the Cabra; pop. about 12,000. It has a trade in corn and wine, and is remarka-

ble for its white houses and clean streets. It contains three handsome public squares and a dismantled Moorish castle.

AGUILAR, Grace, an English authoress, born at Hackney, near London, June 2, 1816, died in Frankfort on-the-Main, Sept. 16, 1847. She was descended from a family of Jewish merchants in Spain, who fled from that country on account of religious persecution, and found a refuge in England. She was instructed wholly by her father and mother. At 14 she commenced the study of history, beginning with Josephus. Her first work was "The Magic Wreath," a small volume of poems, published anonymously. At a very early age she wrote a pleasing religious fiction, "The Martyr, or the Vale of Cedars." Her other works are: "The Spirit of Judaism"; "Israel Defended," translated from the French; "The Days of Bruce," a story from Scottish history; "Jewish Faith"; "Women of Israel"; "Home Scenes and Heart Studies"; "Home Influence"; "Josephine, or the Edict and Escape"; "The Mother's Recompense"; and "Woman's Friendship." In 1835 her constitution received a severe shock from an attack of measles, which left her in a state of debility from which she never fully recovered. She died on a visit to the continent for the benefit of her health, and was buried in the cemetery of the Jews at Frankfort.

AGUIRRE. I. José Saenz de, a learned Spanish Benedictine, born in Logroño, March 24, 1630, died in Rome, Aug. 19, 1699. He was professor of theology at Salamanca, afterward secretary of the inquisition, and finally a cardinal. His principal works are: *Defensio Cathedra Sancti Petri*, for which he received his cardinal's hat; *Sancti Anselmi Theologia* (3 vols. folio); and *Collectio Consiliorum Hispania* (several editions in 4 and 6 vols. folio). **II. Lope de**, a Spaniard of the 16th century, notorious for his crimes. He left Spain for Peru, and accompanied the expedition of Orsua in quest of the imaginary El Dorado, a history of which has been written by Southey. He prompted Orsua to assume regal authority, and then killed him to usurp his place, and from this time murdered all who in any way displeased him. Being finally deserted, he was put to death by the Spanish authorities in Venezuela.

AGULHAS (Port., needles), a cape and bank on the southernmost point of Africa, about 100 m. E. S. E. of the Cape of Good Hope, in lat. 34° 51' S., lon. 20° 2' E. Its extreme height is 455 feet above the sea. A lighthouse was erected in 1849 upon the cape, at an elevation of 52 feet above high water.

AGUSTINA, known as the maid of Saragossa, died at Cueta, Spain, in June, 1857, at a very advanced age. She was an itinerant seller of cool drinks in Saragossa in her youth, and during the siege of that place by the French in 1808 and 1809 distinguished herself by her heroic participation in the severest encounters with the enemy. She was called *la artillera*, from having snatched the match from the

hands of a dying artilleryman, and discharged the piece at the invaders. For her services during this siege she was made a sub-lieutenant in the Spanish army, and received several decorations. Byron has celebrated her in "Childe Harold."

AGYNIAM, or *Agyonii* (Gr. *á*, without, and *γνῶσις*, woman), a sect so called from their rejection of marriage. They flourished about the close of the 7th century, belonging to the later representatives of the Gnostic idea that the creator of the material world was an evil being, and that therefore the true Christian life consists in a renunciation and mortification of all the physical appetites and passions.

AHAB, son and successor of Omri, king of Israel, reigned from 918 to 897 B. C. He married Jezebel, the daughter of Ethbaal, king of the Sidonians. Through her influence the intercourse between Phœnicia and Israel, which had long been only commercial, now became social and religious. She introduced the worship of Baal and Astarte into the Hebrew cultus. The golden calves at Dan and Bethel had been guardedly worshipped for several years; but idolatry became under Ahab a predominant element of religious life. For his idolatrous as well as tyrannical practices, Ahab was reproved by Elijah; and as a result of the king's obstinacy, the prophet proposed the trial of Carmel. Benhadad, king of Syria, twice besieged Ahab's capital, but was defeated with great loss. Ahab came to his end by an arrow wound received while fighting in disguise in the battle of Ramoth-Gilead.

AHANTA, a narrow strip of the Gold Coast, in the kingdom of Ashantee, Africa, between lon. 3° and 2° 10' W. On the west it is bounded by a river called Ancobra by the Portuguese, and Seenna by the natives. It is subdivided into three districts. Its most important town is Boosooa. Great Britain has several forts along the coast, including Axim and Dixcove, all but the latter ceded by the Dutch in 1872. Toward the close of the 17th century there was also a Fort Brandenburg, belonging to the electorate of that name.

AHÁSĒRUS, the name of the Persian king whose actions are described in the book of Esther. (See ESTHER.) Two other kings of the same name are mentioned in Ezra iv. 6, and Dan. ix. 1, and supposed to be identical with Cambyses and Astyages (or Cyaxares) respectively.

AHAZ, king of Judah, 741-725 B. C. See HEBREWS.

AHAZIAH. I. Son and successor of Ahab, king of Israel, reigned 897-895 B. C. The most signal event of his reign was the revolt of the Moabites. Ahaziah, like his father Ahab, was controlled by the ambitious Jezebel, and walked in the ways of his father. He fell from a roof of his palace, and sent to the oracle of Baal-zebub at Ekron to inquire if he should recover. The prophet Elijah met the messengers on the way, and sent them back to say to the

king that he should never rise from his bed. **H.** Son and successor of Jehoram, king of Judah. He reigned but one year, and during that time he was under the entire control of his mother Athaliah, the daughter of Omri, and sister of Ahab, king of Israel. He was slain (884 B. C.) by Jehu, who regarded Ahaziah as coming by blood into the scope of his commission to destroy the house of Ahab.

AHIMELECH, son of Ahitub, a Jewish high priest dwelling at Nob. David, fleeing from Saul, came to Ahimelech, and by a misrepresentation induced him to supply his wants with the shew-bread which was kept in the tabernacle. The priest also gave him the sword of Goliath. For this Saul caused Doeg to slay Ahimelech with all the priests of Nob.

AHITHOPHEL, the confederate and adviser of Absalom in his rebellion against his father David. He was famous for his sagacity and almost considered infallible. The advice of Cushai having been preferred to his by Absalom, he committed suicide by hanging.

AHLEFELD, *Charlotte Sophie Luise Wilhelmine von*, a German novelist, born near Weimar, Dec. 6, 1781, died at Teplitz, July 27, 1849. She married Herr von Ahlefeld, of Schleswig-Holstein, in 1798, and was separated from him in 1807. Goethe expressed a high opinion of her precocious literary talent. She published a great number of sentimental novels, under the name of Elisa Selbig and under her own name (1797-1832), as well as a volume of poetry (Weimar, 1826), under the name of Natalie.

AHLEFELD, *Johann Friedrich*, a German clergyman, born at Mehringen, Nov. 1, 1810. He has been celebrated since 1851 as a pulpit orator at the St. Nicholas church in Leipzig. Nearly 20 volumes of his sermons have been published since 1848, and passed through many editions. He is an orthodox Lutheran.

AHLQUIST, *August Engelbert*, a Finnish philologist and poet, professor of philology and Finnish literature at Helsingfors, born at Kuopio, Aug. 7, 1826. He is distinguished for his philological and ethnographical investigations, especially those in respect to the dialects and races of the Uralo-Altaic family. He published the results of his researches in Finland and Russia in a work entitled *Muistelmia matkoilta Wenäjällä ruosina 1853-8* (Helsingfors, 1860). He is also the author of a grammar of the language of the almost extinct Wot tribe (*Wotisk Grammatik*). In 1847 he founded at Helsingfors a journal entitled *Suometar* (Finland). His collected poetry has been published under the title of *Säkeniä* ("Sparks"). He has also made Finnish translations of several of Schiller's works.

AHLWARDT, *Theodor Wilhelm*, a German orientalist, born at Greifswald, July 4, 1828. He is the son of the philologist and Hellenist Christian Wilhelm Ahlwardt (1760-1830), and has been since 1861 professor of oriental languages at the Greifswald university. He is a high authority on Arabic literature and history.

His principal original work is *Ueber Poesie und Poetik der Araber* (Gotha, 1856).

AHMED SHAH, founder of the Afghan monarchy, born about 1724, died in 1773. Ahmed was the son of Sammaun Khan, the amir of the great tribe of the Abdallis and of the family of the Suddosis. At his father's death he and his brother Zulficar fell into the power of Hussein Shah, the head of the tribe of the Ghiljis, who was then master of Candahar. At this period Afghanistan was subject to Persia. On the invasion of India by Nadir Shah, the two young princes were rescued from the hands of Hussein and sent into Persia. Ahmed's brother died in captivity, but he himself was taken into the service of the usurper, and promoted to the command of a body of horse. When Nadir was assassinated in 1747, Ahmed and his tribe attempted to avenge his death. But finding the Persian army too powerful, he retreated into the fastnesses of his native country, changed the name of his tribe from Abdalli to Durrani, which they still retain, raised the standard of independence, proclaimed himself shah, and was soon joined by the amirs and their several tribes. His first act was to seize a convoy of treasure coming from India to Persia, and to possess himself of the famed Koh-i-noor diamond (now in possession of the British crown), which had fallen into the hands of Nadir Shah. Aware that his power depended on finding occupation for his turbulent subjects, he led them at once to conquest, and rapidly subdued the provinces surrounding his realm and part of the kingdom of Persia. He then directed his arms to India, overran the Punjab and Cashmere (1752), and penetrated (1756-7) as far as Delhi, the capital of the Mogul emperor Alamghir, whither that monarch, jealous of his vizier's excessive power, is said to have earnestly summoned him. The crafty vizier, Ghazy-ed-Deen, propitiated Ahmed, and, professing entire subservience to his views, induced the Afghan monarch to leave him in possession of his ill-gotten power as a check upon his sovereign. Ahmed entered Delhi in triumph, sacked it, and invested his son, Timour Shah, with the government of the Punjab and of Sirhind. In retiring from Delhi, he left a lieutenant to hold both the vizier and the Great Mozul in check. No sooner was the restraint of his presence removed than the minister rose on the Afghan commander, drove him out of Delhi, and assassinated the emperor, placing a prince of the blood royal on the throne. The Mahratta chieftains now saw their opportunity for expelling the Mohammedan rulers altogether, and establishing Hindoo supremacy. Ahmed Shah brought a powerful army into the field (1759). More than a year was spent in manoeuvres and skirmishes, till the Mahrattas took up an entrenched position at Paniput, when Ahmed cut off their supplies, and forced them to an engagement, Jan. 6, 1761, in which the Mahrattas sustained a decisive defeat. The shah, however, saw the impossibility of maintaining

the Mogul empire, and left it to its fate. The Sikh chieftains in the Punjab revolted against him, and he crossed the Indus for the sixth time in 1762, and coerced them to a temporary obedience, which they finally threw off after a seventh expedition of Ahmed in 1763-'4, made unsuccessful by the desertion of part of his army. He was succeeded by his son Timour.

AHMEDABAD, or **Ahmadabad**, a fortified town of British India, capital of a district of the same name, in the presidency of Bombay, on the Subbermutti, 50 m. N. of the bay of Cambay, and 309 m. by railway N. of Bombay; lat. 23° 1' N., lon. 72° 42' E.; pop. about 130,000. The city is 6 m. in circumference, and is surrounded by high walls with towers. It was founded in 1426 by Ahmed, shah of Guzerat, as a capital. Its splendor was increased under Akbar and his successors (1572-1712); and in the 17th century it was the finest city of Hindostan. It was also noted for its commercial prosperity, having a large trade in indigo, cotton, and opium, and manufactures of gold, silver, and silk; but it was ruined by the Mahratta rule, which was not finally extinguished by the English till 1818. The most gorgeous relics of Ahmedabad are the great mosque, the mosque of Sujat Khan, the fire temple, and the tower of silence of the Parsees. The once famous gardens are nearly destroyed; but the environs are still remarkable for their beauty. Col. Briggs's work, "The Architecture of Ahmedabad," beautifully illustrated, was published in London in 1866.

AHMEDNUGGUR, or **Ahmadnagar**. **I.** A district, familiarly called Nagar, including the sub-collectorate of Nasik, in the Poona division of the presidency of Bombay, British India; area about 10,000 sq. m.; pop. upward of 1,000,000, including nearly 200,000 members of wild tribes and low castes, and 50,000 Moslems. **II.** A town, capital of the district, 70 m. N. E. of Poona, and 125 m. E. of Bombay, on the river Seena; pop. about 30,000. The fortress, one mile in circumference, surrounded by a stone wall 30 feet high, and by a broad and deep ditch, and flanked by round towers, is one of the strongest in India. In addition to stone walls, the city is defended by an impenetrable hedge of prickly pear about 20 feet high. The locality is renowned for boar hunting, and abounds in game. The malaria, formerly deadly, was removed by draining previous to 1829, when the headquarters of the Bombay artillery was established here. The city was founded in 1493 by Ahmed Nizam Shah. It was part of the Mogul empire from 1634 to 1707, when it was captured by the Mahrattas. In 1797 it was taken by Sindia, from whom it was wrested by Gen. Wellesley in 1803. Soon afterward, however, it was restored to the peishwa, and it did not finally revert to English authority till 1817.

AH. Johann Franz, a German grammarian, born in Aix-la-Chapelle, Dec. 15, 1796, died at Neuss, Aug. 21, 1865. He was for many years

a teacher in the *Realschule* at Neuss. His method for the acquisition of foreign languages became very popular. His *Praktischer Lehrgang zur schnellen und leichten Erlernung der französischen Sprache* passed through 167 editions between 1834 and 1870. Besides several manuals of the German and other languages, and hand-books of conversation, letter-writing, &c., he published in English a collection entitled "Poetry of Germany" (Leipsic, 1859), and in French *L'Allemagne poétique* (1861).

AHRENS, Heinrich, a German jurist and psychologist, born at Kniestedt, Hanover, July 14, 1808. He studied at Göttingen, and was implicated in the political disturbances of 1831, afterward lectured in Paris on German philosophy and psychology, and from 1834 to 1848 was professor of philosophy at Brussels, declining invitations from the universities of Leyden and Utrecht. In 1848 he was a member of the Frankfort parliament and of the committee appointed to draw up a German constitution. In 1850 he was appointed professor at Gratz, and since 1859 he has been connected with the university of Leipsic, which he represents in the first Saxon chamber. He has published in French *Cours de psychologie* (2 vols., Paris, 1837-'8), and *Cours du droit naturel* (Paris, 1838; 5th ed., 1860). He published a German version of the latter under the title of *Die Rechtsphilosophie, oder das Naturrecht auf philosophisch-anthropologischer Grundlage* (Vienna, 1851). This work has also been translated into Italian, Spanish, Portuguese, and Hungarian, and is used as a basis for academical studies in Brazil, Peru, and Chili. It forms the first part of his great work *Philosophie des Rechts*. The second part contains *Die organische Staatslehre* (Vienna, 1850) and *Die juristische Encyclopädie* (1855-'7).

AHRIMAN, the name of the evil principle in the ancient Persian religion. See ORMUZD.

AHWAZ, or **Ahwuz**, a small town on the river Karun in Persia, province of Khuzistan, 70 m. N. N. E. of Bassorah, and 45 m. S. S. W. of Shuster. It is a very insignificant place, containing about 1,600 inhabitants, but it is in the immediate neighborhood of a vast collection of ruins, the remains of a city ascribed to the period of the Parthian empire, and which was very prosperous under the caliphs. It must have been a city of considerable magnitude, and the ruins extend for 12 miles along the bank of the river. Near it is a strong dam built across the bed of the river to irrigate the surrounding country; and there are remains of a fine bridge and a large palace.

AI, an ancient city of Palestine, in the territory of Benjamin, about 12 m. N. of Jerusalem, as near as can at present be determined. It is first mentioned in Scripture as the place where Abraham and Lot pitched their tents when journeying from Haran. It was captured and destroyed by Joshua, and became a heap of stones, but was rebuilt so as to be a place of some note in the time of Jeremiah.

AIDAN, St. an Irish missionary to the Northumbrians, died Aug. 31, 651. He was sent into Northumbria at the request of King Oswald about 635, and appointed bishop, with a see at Lindisfarne, where he established the monastic rule of St. Columbanus. With the assistance of the king, who acted as his interpreter, he founded the church in Northumbria.

AIDIN, I. A Turkish province, one of the eyalets of Asia Minor, embracing ancient Lydia, Caria, the western part of Lycia, and south-western Phrygia; pop. 450,000. **II.** A city (surnamed *Guzel Hisar*, beautiful castle), capital of the province, about 57 m. S. E. of Smyrna; pop. upward of 40,000, chiefly Turks. It is picturesquely situated on the Mæander, and built out of the ruins of ancient Tralles, which was situated on the plateau of the Messogis above the town. Its important trade in cotton, figs, and other products has become still more active since the recent completion of the Smyrna-Aidin railway. The city is noted for its animation, and possesses many khans, bazaars, mosques, and palaces, as well as some interesting ruins. The American missionaries at Smyrna have a sub-mission here.

AIGUEBELLE, a small town of France, in Savoy, on the left side of the river Arc, 15 m. E. of Chambéry, where the Spanish and French forces gained a victory over the troops of the king of Sardinia in 1742. It is near the beginning of the road which Napoleon built over Mont Cenis.

AIGUEBELLE, Paul Alexandre Nevene d', a Franco-Chinese naval commander, born in France, Jan. 7, 1831. He entered the French navy in 1846, rose to the rank of lieutenant in 1858, and afterward entered the Chinese service, distinguishing himself in 1862-'4 against the Taepings. Admiral Protet and the captains of artillery Lebreton and De Moïdry having been successively killed by their own raw troops, D'Aiguebelle became chief commander of the Franco-Chinese corps, compelled the insurgents to evacuate several towns, and captured Hangchow (1864). In 1865 he was made an officer of the legion of honor by the French government, while the Chinese raised him to the rank of a mandarin of the first class. He established with the aid of M. Gicquel the arsenal of Foo-chow-foo, and enabled the Chinese in less than three years to construct all kinds of European vessels. The first Chinese man-of-war is said to have been launched under D'Aiguebelle's auspices, June 2, 1869, on which occasion he was appointed grand admiral of the Chinese fleet.

AIGUILLE (Fr., needle), a name given to certain narrow and sharp-pointed peaks of the Alps, some of which rise to a great height. Also the special name of a mountain in Isère, France, between Grenoble and Gap, 6,500 feet high, which is inaccessible and called one of the seven wonders of Dauphiné.

AIGILLON, Armand Viguerot Duplessis Richelieu, duc d', minister of foreign affairs under Louis

XV., born in 1720, died in 1782. When in 1758 the English made a descent upon the coast of Brittany, the duke, who was governor of the province, threw himself into a mill, whereupon La Chalotais perpetrated his celebrated witticism, that D'Aiguillon had covered himself, not with glory, but with flour. On the accession of Louis XVI. he was replaced by Vergennes, and lived thenceforth in obscurity. During his ministry (1771-'4), which he owed to his accomplishments as a courtier and the favor of the king's mistress, Mme. Dubarry, the first partition of Poland took place. Louis XV., speaking of this act, so disastrous to the interests of France, exclaimed, "If Choiseul had been here, this partition would not have taken place."

AIGUES-MORTES (Lat. *Aqua Mortua*, dead waters), a town of France, department of Gard, 3 m. from the Mediterranean and 20 m. S. S. W. of Nîmes; pop. in 1866, 3,932. It owes its name to the malarious marshes which surround it, and over which it is approached by a raised causeway. In the middle ages it had a commodious port and ship canal, where Louis XII. embarked his army for the crusades in 1248 and 1270; but they have long been filled up with sand. Several fruitless attempts have been made to restore them, the last by Napoleon I. The walls and towers then built around the town are the best preserved of any in France. In the vicinity are the immense salines of Peccais, and their products, as well as fresh and salted fish, are shipped through canals to the coast and interior.

AIKEN, a township and village in Aiken county (recently formed), S. C., on the S. C. railroad, 120 m. N. W. of Charleston, and 17 m. E. N. E. of Augusta, Ga.; pop. in 1870, 2,259, of whom 1,096 were colored. The surrounding country is somewhat hilly, the ground high, and the air dry and healthful. The climate in winter is mild, and in summer salubrious. Aiken has recently been much resorted to by consumptives and other invalids.

AIKIN, I. John, an English author, son of Dr. John Aikin, tutor in divinity at the dissenters' academy in Warrington, born in Leicestershire, Jan. 15, 1747, died Dec. 7, 1822. In 1798 he gave up the medical profession for literary pursuits. The best known of his works, in which he was assisted by his sister, Mrs. Barbauld, is "Evenings at Home," a selection of instructive essays and anecdotes for children (revised by Cecil Hartley, 1865). This is still popular, and has been translated into every European language. He was literary editor of the "Monthly Magazine" for the first 10 years after its establishment in 1796, and in 1811 was editor of Dodsley's "Annual Register." His works are very numerous. The principal are: "Biographical Memoirs of Medicine in Great Britain from the Time of Henry VIII.," "The Calendar of the Year," afterward republished as "The Natural History of the Year," remarkable for its con-

eiseness; "England Delineated"; "A Memoir of Howard the Philanthropist," with whom he had intimate friendship; "General Biography" (10 vols. 4to). In medicine he rewrote Lewis's "Materia Medica," and some smaller works.

II. Arthur, son of the preceding, born May 19, 1773, died in Bloomsbury, April 15, 1854. In 1797 he published the "Journal of a Tour through North Wales and Shropshire." From 1803 to 1808 he was editor of the "Annual Review." In connection with his brother Charles, he published in 1807 "A Dictionary of Chemistry and Mineralogy." In 1814 appeared the first edition of his "Manual of Mineralogy." He was for many years resident secretary of the society of arts, and contributed to its "Transactions." He was also one of the founders of the geological society, and for 36 years a fellow of the Linnæan society. **III. Lucy**, an English authoress, sister of the preceding, born at Warrington, Nov. 6, 1781, died at Hampstead, Jan. 29, 1864. After having assisted her father and aunt (Mrs. Barbauld) in their literary work, she published a poetical volume in 1810 under the title of "Epistles to Women," modelled after the style of Pope. Her most important works are her memoirs of the courts of Elizabeth (1818), James I. (1822), and Charles I. (1833), and her "Memoirs of Addison" (1843). She also wrote memoirs of her father and her aunt. She was regarded as one of the most accomplished literary women of her time, and was also celebrated for her conversational powers and her social qualities.

AIKMAN, William, a Scottish portrait painter, born Oct. 24, 1682, died in London, June 4, 1731. He spent three years in Italy, travelled in Turkey, practised his art some years in Edinburgh, and in 1723 settled in London, where he was liberally patronized, and on intimate terms with the leading spirits in art and letters. His works closely resemble those of Sir Godfrey Kneller.

AILANTUS (Malay, *ailanto*, tree of heaven, the name of one species in the Mollucas), a tree of the sub-family *ailanteæ*, which is one of the four divisions of *simarubaceæ* of Lindley. The species *A. glandulosa*, native of China, was introduced into England in 1751, and into North America about the beginning of this century. The tree resembles a gigantic stag's horn sumach, with very large leaves, unequally pinnate, and footstalks from one to two feet in length. It has many flowers on a terminal pedicel, whose anthers smell disagreeably, like animal effluvia containing phosphorus. It grows very fast, especially in poor calcareous soil, and has spreading roots. There is a resinous juice in the bark, which hardens in a short time. The wood is hard, heavy, glossy, and susceptible of a fine polish. It is propagated by root-cuttings. It sometimes has only male flowers, but in warm countries produces both male and female, and consequently fruit. *A. excelsa* is found about Delhi and further

south. There are other species in southern Asia, and on the islands of the Indian ocean. The other plants of the same order are natives of tropical America, India, and Africa.

AILLY, Pierre d', or **Petrus de Alliaco**, a French prelate and theologian, surnamed the Hammer of Heretics and the Eagle of the Doctors of France, born in 1350, died in 1420 or 1425. He was distinguished as a preacher and philosophical disputant (being a leader of the nominalists), and early became a doctor of the Sorbonne, in 1384 grand master of the college of Navarre, in 1389 chancellor of the university, and in 1398 bishop of Cambrai; he was also almoner and confessor to Charles VI. His exertions led to the calling of the council of Pisa in 1409, for the healing of the papal schism, and he was one of its most active members. He was made cardinal by John XXIII. and sent as papal legate to Germany. In this capacity he took a prominent part in the council of Constance, 1414-'18, where he promoted the condemnation of John Huss and Jerome of Prague, but zealously advocated a reform in the church, maintained the superiority of councils to the popes, and aided in the election of Martin V. in place of the three rival popes. He was afterward papal legate at Avignon till his death. His published writings are numerous, including *Concordantia Astronomiæ cum Theologia*, &c., written in accordance with the astrological views of the age.

AILRED, Ealred, or Ethelred, an English historian and theologian, born in 1104, died June 12, 1166. He was educated at the Scottish court, entered the Cistercian order, and became abbot of Revesby in Lincolnshire, and afterward of Rievaulx in Yorkshire. His extraordinary sanctity is said to have been attested by miracles both before and after his death. His numerous works (in Latin) include a life of Edward the Confessor, an account of the battle of the Standard, and other historical pieces, published by Sir Roger Twysden in *Historiæ Anglicanæ Scriptores decem* (2 vols. fol., 1652); "Mirror of Divine Love," "Mirror of Charity," sermons, &c., partly published at Douai in 1631, and in several collections.

AILSA CRAIG, an isolated rocky islet or Ayrshire, Scotland, 10 m. off the coast at Girvan, and 25 m. S. S. W. of Ayr; lat. 55° 15' 12" N., lon. 5° 7' W. It is of conical shape, about two miles in circumference at the base, and rises 1,098 feet above the surface of the ocean. Its summit can only be gained on the E. side; the other sides are nearly perpendicular, two of them resembling in structure the columns of Fingal's cave. The top is covered with verdure, and is the resort of great numbers of sea birds, goats, and rabbits; and there are the ruins of an ancient three-story tower. The island is the property of the marquis of Ailsa, who takes his title from it.

AIMARD, Gustave, a French novelist, born about 1818. He made a voyage as a cabin boy to America, and spent ten adventurous years

in Arkansas, Mexico, and other parts of this continent. He next figured as a traveller and soldier of fortune in Spain, Turkey, and the Caucasus, served in the mobile guard in Paris in 1848, and eventually gave the story of his experiences and adventures in a series of novels, among which are *Les trappeurs de l'Arkansas* (1858), *Les nuits Mexicaines* (1863), and *L'Arcaucan* (1864). Several of his tales have been translated into English.

AIMÉ-MARTIN, Louis, a French author, born in Lyons in 1781, died in Paris, June 22, 1847. In 1815 he was appointed editing secretary of the chamber of deputies, and soon afterward professor of belles-lettres, moral philosophy, and history in the polytechnic school, of which office he was deprived in 1831. He then became keeper of the library of Ste. Geneviève. His first successful production was a semi-scientific book, called *Lettres à Sophie sur la physique, la chimie et l'histoire naturelle* (2 vols. 8vo, 1810), an agreeable mixture of prose and verse, suggested by the extraordinary success of the *Lettres à Emilie sur la mythologie* by Demoustier. He wrote a little later *La vie de Bernardin de St. Pierre*, in which the biographer happily imitated the style of his subject. His commentaries on Racine and Molière are especially interesting and tasteful. His most important work is a treatise entitled *Éducation des mères de famille*, in which he asserts that the best, or rather the only means of improving mankind, and reforming our present social organization, is to educate women in such a manner that they may be enabled to form men of character and virtue. The first part of the book is interesting, containing many practical suggestions, but the second part is much less valuable. A good translation of it has been published in the United States.—His wife, born about 1782, died in November, 1847, was a daughter of the marquis de Belleport. At the age of 18 she had married Bernardin de St. Pierre, then a widower in his 63d year. She was a favorite with many of her celebrated contemporaries, especially Lamartine, to whom she bequeathed her fortune.

AIMON, or **Aymon**, the four sons of, Alard, Richard, Guiscard, and Renaud, are among the most illustrious of the warriors and heroes celebrated in the mediæval romances of chivalry. Aimon is variously reported to have been duke of Dordogna, prince of Ardennes, and provincial governor under Charlemagne. Froissart seriously relates their eventful career, but by the moderns their existence has been transferred from the realm of history to that of poetry. The eldest, Renaud or Roland, is the hero of the "Orlando Furioso" of Ariosto. Their adventures with those of their single horse, famed under the name of Bayard, were probably at first oral traditions in Provence, but have been repeated in various forms in the literature of every European nation.

AIN, a department of France in Burgundy, bounded by Saône-et-Loire, Jura, Switzerland,

Haute-Savoie, Savoie, Isère, and Rhône; area, 2,239 sq. m.; pop. in 1872, 336,290. The Rhône flows on its eastern and southern borders, and the Saône on the western. The eastern section of the department is traversed by mountain ranges and deep valleys. The western division is low, level, and swampy, and dotted with numerous ponds. The river Ain, an affluent of the Rhône, flows through the centre, and has many saw and grist mills on its banks. Immense rafts of timber are floated down its rapid current to Lyons. The products of the department are chiefly agricultural. Sheep are reared in great numbers in the eastern part. It is divided into the arrondissements of Bourg, Belley, Nantua, Trévoux, and Gex. Capital, Bourg-en-Bresse.

AIN-MADHI, a walled town and oasis of the Algerian desert, about 200 m. S. S. W. of Algiers; pop. about 2,000. The town is built on a rocky eminence amid gardens, surrounded by an arid plain. It is a station for caravans, and possesses a considerable trade. It was the seat of an independent Arab chief till 1852.

AINMÜLLER, Maximilian Emanuel, a German artist, founder of the modern school of glass painting, born in Munich, Feb. 14, 1807, died there, Dec. 8, 1870. His talent as a decorative and monumental architect aided him essentially in the glass paintings which, under the patronage of King Louis I. of Bavaria, he executed or restored for many of the religious buildings of Europe. He was also employed at Westminster abbey, St. George's chapel, Windsor, and St. Peter's college, Cambridge; and at the instance of Mr. Beresford Hope he executed 14 paintings for a cathedral in Ireland. Among his master works are the painted windows in the cathedral of Cologne, and those in the Vatican representing St. Peter and St. Paul. The most remarkable of his works, by their stupendous size, are in the cathedral of Glasgow. With the assistance of his surviving son and pupil, HEINRICH (born 1836), he had completed up to 1864 40 windows with upward of 100 biblical and historical paintings. He was royal inspector of the academy of glass painting at Munich. He also excelled as an architectural painter in oil, and there are many of his works in the art galleries of St. Petersburg, Munich, Vienna, and other parts of Europe.

AINOS, or **Ainus** (*i. e.*, men), tribes inhabiting Saghalien, Yesso, and the Kurile islands, and various adjacent regions, partly under Japanese and partly under Russian jurisdiction, the latter being generally called Kuriles. Tradition says that the Japanese were originally Ainos, and only became a distinct race by intermarrying with Chinese. The Ainos are different from other Mongolian tribes, and in their more vigorous physical formation assimilate to some extent to the Caucasian type. Though armed and painted like savages, they are inoffensive and hospitable, but shy of Japanese and Russians, especially on the coasts of the Saghalien islands, which they formerly occupied exclusive-

ly, and where the Gilanes tribe at present inhabit the N. part. The extravagant stories of travellers caused the Ainos in the Kurile islands to be designated as the hairy Kuriles, though their bodies are not particularly hairy and their beards seldom longer than 5 or 6 inches. They are pagans, and sacrifice the first of the animals they kill, generally bears, to their idols. They are polygamists, groups of 10 to 12 families living together in miserable huts, with a chief for each group. They support themselves by fishing and hunting. The Aino language is divided into several dialects, and is regarded by Siebold as somewhat connected with the Japanese, but this opinion is not generally entertained. It is polysyllabic, has an alphabet of 47 letters, and is written in four different sets of characters, one of them, the Katakana, being sometimes called the writing of men, and another, the Kiragena, that of women. August Pfizmaier published a description of it (Vienna, 1852), and a vocabulary (1854).

AINSWORTH, Henry, an English nonconformist divine, the date and place of whose birth are unknown, died in Amsterdam in 1622. In 1590 he attached himself to the Brownist sect, and was afterward compelled by persecution to fly to Holland, where, in connection with a Mr. Johnson, he established a church at Amsterdam. He was a good Hebrew scholar, and published annotations on the Psalms and Pentateuch, together with a literal translation of the latter, a translation of Solomon's Song, and other works of a somewhat similar character.

AINSWORTH, Robert, an English teacher and scholar, born in Lancashire in September, 1660, died in London, April 4, 1743. He taught private schools in and near London, and early retired with a competency. His only claim to remembrance is his English-Latin and Latin-English dictionary, commenced in 1714 and first published in 1736. It was edited and reprinted many times, in 2 vols. 4to or folio; and abridgments of it were used in nearly all English and American schools till near the middle of the present century, when it was generally superseded by more accurate works.

AINSWORTH, I. William Francis, an English traveller, geologist, and physician, born in Exeter, Nov. 9, 1807. After having studied medicine at Edinburgh, he made geological excursions into Auvergne and the Pyrenees. In 1828 he took charge of the Edinburgh "Journal of Natural and Geographical Science," and delivered lectures on geology. He was attached to a cholera hospital in London in 1832, and afterward to various hospitals in Ireland. In 1835 he was appointed surgeon and geologist to Col. Chesney's expedition to explore the Euphrates and the route from that river to the Mediterranean, and in 1838 he was sent with Rassam and Theodore Russell, by the geological and Bible societies of London, to trace the course of the river Kizil-Irmak (the ancient Halys), and to visit the Nestorian Christians of Kurdistan. He has published "Researches in Assyria, Baby-

lonia, and Chaldea" (1838); "Travels and Researches in Asia Minor, Mesopotamia, Chaldea, and Armenia" (2 vols., 1842); "The Claims of the Christian Aborigines in the East"; "Travels in the Track of the 10,000 Greeks" (1844); the "Illustrated Universal Gazetteer" (1861-'3), &c. **II. William Harrison**, an English novelist, cousin of the preceding, born in Manchester, Feb. 4, 1805. His father was an attorney, and he was intended for the law, but from an early age he exhibited a strong taste for literature. A novel, "Sir John Cheverton," which he produced in 1825, was shown to Sir Walter Scott, whose praises encouraged Ainsworth to pursue the course he had thus commenced. In 1834 his "Rookwood" appeared, founded on the adventures of the noted highwayman Dick Turpin; and the popularity of this novel induced him to bring out "Jack Sheppard." The robber school of romance having fixed Mr. Ainsworth's celebrity, he turned to a more wholesome style of literature, and produced various novels of local interest, in which historical characters are introduced and very freely dealt with. Such are his "Tower of London," "Guy Fawkes," "Old St. Paul's," "Windsor Castle," "The Constable of the Tower," and "Cardinal Pole." In 1845 he became proprietor of Colburn's "New Monthly," which he still conducts (1872); and for a few years he also edited a second periodical called "Ainsworth's Magazine." His most recent novels are "The Miser's Daughter" (1869), "Hilary St. Ives" (1870), and "Boscobel, or the Royal Oak" (1872).

AINTAB (according to some, the ancient *Antiochia ad Taurum*), a city of Asiatic Turkey, in the vilayet of Aleppo, and about 70 m. N. by E. from Aleppo; pop. estimated at from 35,000 to 43,000, including 12,000 Armenians. It has large manufactures of silk, leather, and cotton goods, and the mountain fort which is connected with it makes it an important military point. Aintab is one of the centres of the American Protestant missions, and in 1869 had 1,900 registered Protestants. It was conquered in 1183 by Saladin, and in 1400 by Timour. Near Aintab is the village of Nizib, where Ibrahim Pasha on June 24, 1839, obtained a great victory over the Turks under Hafiz Pasla.

AIR (Gr. *ἀήρ*, Lat. *aer*), a term now limited to the atmospheric air. See ATMOSPHERE.

AIR, or **Asben**, an oasis in the desert of Sahara, situated between lat. 16° and 20° N., and lon. 5° and 10° E. It is bordered by the territory of the Kelowi Tuariks on the north, and by Soodan, or Negroland, on the south. Dr. Barth terms it the Switzerland of the desert, and the frontierland of negrodom. Its northern borders are infested by a savage race who rob and often murder strangers passing through the country. In the north is the mountain group of Gunge, 5,000 feet above the level of the sea. Vegetation thrives in the valleys; it is the northern limit of the doun palm; there are groves swarming with ring doves, hoopoes, and other birds,

and highlands abounding in asses and goats. To the south are the groups of Mt. Bunday, Eghellal, Anderas, and Baghzen. A desert plateau, with an average elevation of 2,000 feet, the home of the giraffe, wild ox, and ostrich, divides Air from Soodan. The inhabitants of Air are blacker and shorter than those of Azkar, and, instead of the austere and regular northern features, have a rounder and more cheerful expression of countenance. The principal places are Agades and Tintellust. This is probably the most southern place in central Africa where the plough is used; for all over Soodan the hoe is the sole implement for preparing the ground. The government of the country is presided over by the sultan of Agades, and his chief vassal is emir of Tintellust. The inhabitants are fanatical Mohammedans. If a man marries a woman of another village, he must go and live in her village, not she in his. The hereditary power does not descend to the son, but to the sister's son. The arms, in general, are the spear, the sword, and the dagger, and an immense shield of antelope hide; some use bows and arrows. A few only have muskets, and those few keep them for show rather than actual use. The valleys are but poorly cultivated, and every piece of clothing material has to be imported, the population being sustained in large part by the salt trade of Bilma. The tolls levied on this article, in return for protection afforded, constitute almost the whole source of revenue to the sheiks of Tintellust, Loosoo, and others. The name Air first appears in the description of Leo Africanus, written in 1526. It was introduced by the Berber conquerors, as Asben is the aboriginal name still used by the black and mixed population.—See Richardson's "Journal of a Mission to Central Africa" (London, 1853), and Dr. Barth's "Travels in Central Africa" (London, 1857).

AIR BLADDER, an organ in some kinds of fishes, commonly called by fishermen the "swim." Fishes endowed with great powers of locomotion, and accustomed to pass rapidly from the surface to the bottom of the ocean, and vice versa, are provided with an air bladder or a swim, by which they can modify at will the specific gravity of their bodies in the water, as birds do in the atmosphere by admitting air when they wish to rise, and by expelling it as they descend. Not that fish draw air into their swims and expel it, as birds do in their quills, &c., but they have the power of generating gas to fill the swim like a balloon within the body when they wish to ascend in the water, and expelling it when they descend. Fishermen are well acquainted with the functions of the bladder in the cod and other species, which require to be brought fresh to market at a great distance from the place where they are caught; they perforate the air bladder with a fine needle, allowing the air to escape, and thus rendering the fish unable to rise from the bottom of the well-boats where they live

for a considerable time, while brought to market. Cod sounds are the salted air bladders of these fishes. The Iceland fishermen, and those of Newfoundland, prepare isinglass from cod sounds; and the Russians make a superior kind of isinglass from the sounds or swims of the sturgeon. The swim is composed of a lengthened sac, sometimes simple, as in the common perch, or divided into several compartments by transverse ligature, as in the trout and salmon; sometimes furnished with appendices, more or less numerous in different species. It is composed of a thick internal coat of fibrous texture, and a thin external coat, the whole being enveloped in the covering of the intestines. The swim has in many species no external opening, and the air or gas with which it is distended is supposed to be secreted in such cases by a glandulous organ with which it is always provided. In fresh-water fishes the air bladder communicates sometimes with the œsophagus and sometimes with the stomach, by means of a small duct or tube; and in these instances no secreting gland is found. A very few species, among which is the common eel, have air bladders opening by an external duct, and also provided with secreting glands. Fishes deprived of their air bladders sink helpless to the bottom of the water, and there remain. All the different species of flat fish, such as skates, soles, turbot, brills, &c., which live only on the coasts and on sand banks at the bottom of the ocean, where they find their food, have no air bladders; their bodies are heavier than water, and their mode of life does not require them to ascend. Mackerel and other species, which find their food entirely on the surface, and remain there, have no air bladders; their bodies are comparatively light, and they need not sink low down in search of food. Some zoölogists have supposed that the air bladder of fishes may be connected with the respiration, and it is now generally admitted to be a rudimentary lung. Much remains to be yet observed with regard to the relation of this organ to the general conformation of fishes; for it is sometimes found in one species, and entirely absent in another which belongs to the same genus.

AIR CELLS, hollow spaces within the cellular tissue of the stems, leaves, and other parts of plants, containing air only, the sap and other matters being contained in different receptacles. They most frequently occur in water plants, and very conspicuously in the splendid *Victoria regia* of the lakes of South America, enabling its rosy leaves to float; and in the *Vol-lisneriu spiralis*, of which the male specimens, immersed in the water, rise from the bottom to meet the long-stalked females which stand over the surface. Other receptacles of air are to be found in the cambium (the layer of gelatinous cellular tissue between the wood and the bark) of trees. Here the longitudinal rows of cells become broader, and exhibit in the progress of growth small flat air bubbles between the walls of the contiguous cells; grad-

ually the bubbles become globular or oval, and after the cell walls have increased in thickness, a small canal is formed within the new mass, giving rise to porous vessels. This is readily observable in limes and willows. The air bubbles obstruct the passage of the sap, and thus cause the consolidation of the wood. The difference between the wood of needle-leaved trees (such as the pine, fir, spruce, larch, &c.) and of broad-leaved trees chiefly depends upon the number of the cells that are converted into porous vessels.

AIRDRIE, a borough town of Lanarkshire, Scotland, 11 m. E. of Glasgow; pop. in 1861, 12,922. It is well built, and has recently grown into importance from the extensive coal and iron mines in the neighborhood, and also from its proximity to Glasgow, whence many of its weavers obtain employment. The laird or proprietor of the estate of Airdrie is Mr. A. J. Alexander, a native and resident of Kentucky, famous as a breeder of fine horses and cattle in Woodford county.

AIRE, a river of Yorkshire, England, rises near Settle, flows S. E., passes Leeds, and receives the Calder at Castleford; and the two, having been widened and deepened, form one of the links in the canal system of Yorkshire and Lancashire, under the name of the Aire and Calder navigation. From Castleford, the Aire flows E. to the Ouse near Goole.

AIRE. I. A fortified city of N. E. France, department of Pas-de-Calais, on the Lys, 8 m. S. S. E. of St. Omer; pop. in 1866, 8,803. It is well built, and has a highly ornamented church. There are manufactures of linen, hats, soap, Dutch tiles, &c. The surrounding district is one of the richest in French Flanders. **II.** A city of S. W. France, department of Landes, on the Adour, 80 m. S. by E. of Bordeaux; pop. in 1866, 4,885. It is a very old place, was formerly strongly fortified, and has suffered much in foreign and civil wars. It was the residence of Alaric II., and has been a bishop's see since the 5th century.

AIR GUN, a pneumatic engine resembling a musket, for the purpose of discharging bullets by means of compressed air. It consists of a lock, stock, barrel, and ramrod. The stock is made hollow, and provided with proper cocks for filling it with compressed air by means of a force pump. The lock is nothing but a valve which lets into the barrel a portion of the air compressed in the stock, when the trigger is pulled. The gun is loaded with wadding and ball in the ordinary way, and the air suddenly introduced from the stock propels it with a velocity proportional to the square root of the degree of compression of the air. There is no doubt that if the discovery of powder had not been made at an early date, these instruments would have reached a point of great effectiveness. The section of the air gun given here represents one of the most practical kind. It has the general form of a musket. The stock A is hollow, and strong

enough to withstand the required pressure of the air, being some 50 atmospheres, pumped into it by means of the piston E, moving in the barrel C D; this compressed air is confined in the

Air Gun.

stock by the spring check valve C. The action of the lock I is such that when pulling the trigger the valve C is for an instant lifted from its seat, which causes a small portion of the air to escape; and as this air is confined under a pressure of some 50 atmospheres or 750 lbs., the impulse given to the ball at the first discharge is almost as great as that of gunpowder. One charge may fire several balls, but the effect decreases with every firing. Some air guns have, in place of a hollow stock, a separate large hollow metallic ball into which the air is compressed, and which is attached to the side of the lock. These are generally very unsafe.—Arms analogous to air guns have been contrived for producing explosion, with nearly or quite the power of an ordinary musket, by the electrical conversion in the barrel of oxygen and hydrogen, or air and street gas, into steam, and other similar means.

AIR PLANTS, a term applied to some species of the families of *Bromeliaceæ* (*Tillandsia usneoides*, hanging in festoons from the forest trees of tropical America, moss-like, and *T. xiphioides*, perfuming the balconies of houses in Buenos Ayres, &c.), and of *orchidaceæ* (namely, the parasitic groups of them, such as the *aërides*, *arachnides*, or *flos aëro* of the East Indies, and many others), because of their being able to live for a considerable time, suspended in the air, without apparently receiving any nutriment. The hot, damp, and shady forests of the torrid zone in Asia, Africa, and America, abound in gracefully and grotesquely shaped and deliciously scented species of *orchideæ*, so that in Java alone there are nearly 300 varieties. During the dry season, which is that of repose, corresponding to our winter in this respect, these parasites wither, lose their leaves, and seem to be dead; but as soon as the gentle, preparatory rain begins to fall, they revive, and become fully developed into their glorious existence by the ceaseless showers that transform the whole surface of the country into a magnificent hothouse. They are attached, amid gigantic grasses, ferns, and numberless climbers, to trees, rocks, &c., and are nourished by the continual warm vapors that fill the forests. Stagnant water is injurious to them, even by mere proximity. The roots of most fully developed air plants, by which they cling to their supports high in the air, have an outer parchment-like layer, in which the spiral cells exhibit detached fibres and simple walls; thus in *oneidium altissimum*,

epilendron elongatum, &c. In order to enjoy these beautiful plants in our houses, we must surround them by the natural circumstances in which they prosper, viz.: rotten wood, a very little chopped moss, and fragments of flower pots for soil, with heat, damp air, light, absence of stagnant water and of impurities.

AIR PUMP, in natural philosophy, a machine for exhausting the air from a vessel. The first machine of this kind was made in 1650 by Otto von Guericke, burgomaster of Magdeburg, shortly after Galileo had discovered that air was ponderable. Since then this instrument has been much improved, principally by Hook, Papin, Boyle, Babinet, Richard, and Deleuil. In its most approved form it consists of a circular brass plate, on which is placed a bell-shaped glass vessel. The interior of this vessel communicates through a tube opening in the centre of the plate with the pump cylinders. The rim of the glass vessel, called the reservoir, is ground perfectly flat, and a little lard is rubbed upon the edge before it is applied on the brass plate, which is likewise ground flat. Thus an air-proof joint is formed. Valves, placed either on the piston or on the cylinders, a stopcock on the pipe, and a mercury vacuum gauge, communicating with the reservoir, complete the machine. At each stroke of the piston, a cylinder full of air is expelled on one side the piston, and the air of the reservoir expands to fill the space on the other side; at the return stroke, this air is expelled in its turn, and so on. The air of the reservoir becomes more and more dilated till the moment when a full cylinder of it, compressed into the small space necessarily left between the piston and the cylinder bottom, has not a sufficient pressure to open the valve; that is to say, when this pressure is less than 14 pounds to the square inch, which is the pressure of the atmosphere acting on the other side of the valve. For this reason these valves are made as light and delicate as possible, and since the beginning of this century they have been made simply of a strip of oiled silk stretched over one or more of the small holes, through which the air can thus only pass in one direction. As by every stroke of the piston the air divides itself equally between the reservoir and the pump cylinder, it is evident that every stroke takes out of the reservoir only a certain fraction of that which is left in it; if, for instance, the capacity of the cylinder is $\frac{1}{30}$ of that of the reservoir, the 30th stroke will by no means take out the last 30th part, but only the 30th part of the air left by the former stroke. As a consequence of this principle of action, a perfect vacuum cannot be produced by any air pump, but it will be approximated more or less according to the perfection of its workmanship. In this workmanship an important point to be observed is, that if at the lowest portion of the piston there is any space left between it and the cylinder, this space will of course remain filled with some

air after the downward stroke of the piston; at the succeeding upward stroke this air will expand, and may fill the cylinder to the same extent as the vessel to be exhausted; this will prevent the opening of the valves, and any further motion of the pump will become useless. It is therefore necessary to avoid this so-called "dead space" in air pumps; a precaution not necessary in pumps for liquids, as these are solid and not elastic like air.—

FIG. 1.—Simplest Form of Air Pump.

An apparatus so extensively used for a great variety of purposes has of course undergone a great many modifications and improvements. We will only describe some of the principal types, commencing with the oldest and most simple. In fig. 1, C is the brass cylinder in which the piston is moved up and down, by means of the handle H. This cylinder is attached to a wooden base A A, which carries also the plate P P, on which the vessel to be exhausted is placed. The hole O in the centre of the plate connects by means of a tube with the lower part of the cylinder C. At the bottom of this cylinder is a cock to admit the air again into the exhausted vessel; there is a valve above this cock, and another valve in the piston, both opening upward. The first air pumps made by Von Guericke were similar, only his cylinder was horizontal and his piston solid, and in place of valves he had stopcocks which had to be turned at every stroke. It is evident that in this pump

FIG. 2.—Double-barrel Air Pump.

only the up stroke requires labor, a portion of which is lost in the beginning of the down stroke, when the atmospheric pressure causes

the piston forcibly to descend for a portion of its motion. To prevent this loss of labor the double-barrel air pump has been contrived, represented in our second figure. By means of a ratchet wheel moved through about 180° by the double handle H C', the pistons are alternately raised and depressed in the cylinders C C' attached to the base A, which also carries the plate P, with the so-called receiver R, which is the strong glass vessel into which the objects to be experimented upon are placed. An important improvement in such air pumps was the imitation of the manner of working of the steam piston and cylinder, namely, closing the top of the cylinder hermetically, by means of a packing box surrounding the piston rod, and the placing of a valve in this upper cylinder head, so as to give a pump with a single cylinder three valves, all opening upward—one in the piston, and two at the top and bottom of the cylinder. In this way the atmospheric pressure does not act on the piston during the downward stroke, as then the top valve closes, and a partial vacuum is formed over the piston, which is filled by the air under the piston passing through its valve. Such an air pump is represented in fig. 3. A is the base; C the

sition of 1867.—In order to do away with the great friction of a close-fitting piston in the barrel, Deleuil made a pump in which the pis-

FIG. 4.—Large Improved Air Pump of Ritchie.

ton does not touch the barrel at all, but leaves a very narrow space between. In order to guide its motion without contact, it has, besides the upper piston rod which moves it, another piston rod with packing box below passing through the under cylinder head. To prevent the air from passing the piston, the latter is a cylinder of great height, nearly half the length of the barrel, and around its circumference are a great number of circular grooves, each of which has to be filled with air before this can pass to the next groove, which takes much more time than each stroke of the piston, so that the pump works as if the piston were tight fitting. But the grooves, filled with air at each stroke, act as so much dead space, and thus as a slight imperfection. Kravogel, of Tyrol, makes his air pump pistons like those of the pump of an hydraulic press, of a simple solid thick iron cylinder, passing through a stuffing box into a barrel which is wider, and in which the space between the two is filled with mercury, thus absolutely annulling all dead space.—Early attempts to produce a vacuum on the Torricellian principle (see BAROMETER) failed, but Geisler succeeded in constructing an air pump on this principle; it is now one of the most valuable tools in the philosophical cabinet. (See figure 5.) The glass tube C, of which the length is about equal to the height of the barometrical tube (30 inches), contains on the top a glass vessel A, while its lower end is connected by a flexible tube D with the glass vessel B. The glass vessel A is connected with a tube T R, provided with a double-way stopcock O P, which

FIG. 3.—Improved Modern Air Pump.

cylinder; P P the plate; S the support for the handle H; E an oil cup, attached to a cap over the top valve, to receive the lubricating fluid which the upward motion of the piston may throw out of the top valve; and R is the receiver, containing the apparatus prepared to demonstrate that the sound of a bell is not transmitted through a vacuum. In order to ease the labor when such a pump has to be used continuously, a fly wheel may be attached, working by means of one or more cranks one or more pistons, as in fig. 4. Babinet made such pumps, in which the air from one cylinder was thrown into a second; and Richard in Paris makes pumps with series of barrels, say eight to each pump, all moved by one axle with cranks. These remarkable pumps possess some other peculiarities, described in Prof. F. A. P. Barnard's report on the Paris expo-

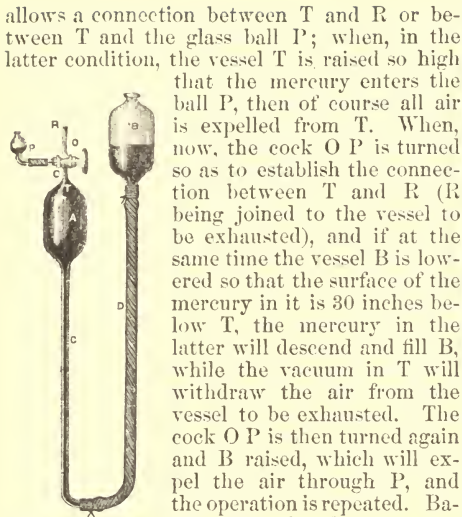

FIG. 5.—Geisler's Mercurial Air Pump.

allows a connection between T and R or between T and the glass ball P; when, in the latter condition, the vessel T is raised so high that the mercury enters the ball P, then of course all air is expelled from T. When, now, the cock O P is turned so as to establish the connection between T and R (R being joined to the vessel to be exhausted), and if at the same time the vessel B is lowered so that the surface of the mercury in it is 30 inches below T, the mercury in the latter will descend and fill B, while the vacuum in T will withdraw the air from the vessel to be exhausted. The cock O P is then turned again and B raised, which will expel the air through P, and the operation is repeated. Babo has modified this apparatus by substituting valves for the stopcock, while Poggendorf

FIG. 6.—Bunsen's Air Suction Pump.

has contrived a very useful combination of this instrument with the ordinary air pump.—Bunsen uses falling water to carry the surrounding air with it (see ADHESION OF LIQUIDS TO GASES), and in this way produces a steady exhaustion of air or vapor from vessels requiring such constant removal. It consists of a wide glass tube D, in which a narrower tube

below with a lead tube F, which reaches 20 to 30 feet down; and this long descending column of water acts like a powerful continuous piston. The amount of rarefaction is ascertained by the difference in the height of the mercurial columns in the syphon barometer P Q. This apparatus is used for driving liquids through filters by atmospheric pressure, for drying in vacuo, &c. Some experimenters, in order to economize water, reverse the operations of the tubes and pass the water out of the central narrow tube, while the suction takes place through the wide tube, in which case the water is passed in at S, while the exhaustion takes place by A; in this case the barometer P Q is also connected with A.—One

FIG. 7.—Doyle and Martin's Rotary Air Pump.

of the most ingenious inventions of this kind is the rotary air pump of Doyle and Martin of New York. It consists of a wheel of which the rim is a hollow tube, filled in its lower portion with mercury, *c c'*, fig. 7; this mercury performs the function of a perfectly fitting piston, with a minimum of friction. When the wheel is revolved rapidly around its axis, the heavy mercury remains of course in its lower portion. The hollow rim possesses two or more stopcocks, *v w*, which in one position allow the mercury to pass, as represented below at *w*, and in another position close the communication between the two sides, and bring each in connection with one of the hollow spokes, as seen at *v* in the top; the position of these cocks is regulated by the levers *m b e* and *n g h*, worked by the stationary grooved cam *k*. If, now, the whole wheel revolves rapidly in the direction of the arrows, the upper cock, being closed, will compress the air at the left side and cause an exhaust at the right side, while the mercury remains below as the cock *w* is open; the two curved spokes, marked "pressure pipe" and "suction pipe," will thus perform their respective functions, till the valve, having reached the mercury be-

low, opens to let the latter pass, closing at the same time the pressure and suction pipes; then the lower cock *w* will become the upper, and while closing perform its functions. The wheel turns on two hollow trunnions, the one in front being connected with the suction pipe, the one behind with the pressure pipe. During rotation the axis will thus perform a continuous suction and pressure, which in order to be considerable requires a wheel of large dimensions; 30 inches difference in the height of the mercury at the two sides corresponding with our atmosphere, a wheel of at least 5 feet diameter is required to produce a vacuum, while if pressure is also required, double and triple these dimensions must be given. The inventors had recently such apparatus in operation with a wheel of 16 feet diameter and containing 2,000 lbs. of mercury. —Air pumps are used by professors of natural philosophy, to show that in a vacuum combustion is arrested, smoke falls like lead, cold water boils, warm-blooded animals die rapidly, fermentation is stopped, &c. The celebrated process of Appert for the preservation of alimentary substances is founded on the last mentioned property; but the necessary vacuum is produced, not by using an air pump, but by boiling the boxes of preserves, thus producing steam that expels the air, and then quickly soldering up the hole while the steam still fills up the space, and before the air is given time to enter; the vacuum will be produced after cooling while the steam is condensed to water. Air pumps are at the present day also used in many manufactories. The sugar refiners use it for the rapid evaporation of the syrup at low temperatures; and the condensation of milk is performed by means of large air pumps. The artificial manufacture of ice, and artificial cooling by the use of power, are always accomplished by the intervention of powerful air pumps, whether air itself is alternately expanded and compressed, or use is made of volatile liquids, as ether, ammonia, and ephymogene, which by evaporating in a vacuum produced by the air pump generate the most intense artificial cold. Many chemical preparations also require the constant use of a vacuum, or at least of very rarefied air, for which reason the air pump is one of the most important tools in all manufactories of chemicals, as well as in the chemical laboratory. Recently the use of the air pump has been introduced for the preservation of wood and other porous material, by first exhausting the air from the pores, so as to force the preserving liquids in by atmospheric pressure. For manufacturers of aneroid barometers, sympiesometers, Geisler's tubes, and other physical instruments, the air pump is also an indispensable tool. Finally, one of the most important applications of the air pump is that to the low-pressure steam engine; it is used to pump out of the condenser the condensed steam, the water introduced for condensing, and the air that has come out of

this water when warmed by the condensation of steam. This application of the air pump is one of the inventions of Watt.

AIR VESSELS, or properly **Spiral Vessels**, are supposed by some botanists to be the only formation by which air is conveyed into the vegetable system; but air has access to many parts of the plant by means independent of the spiral vessels. Spiral vessels differ from spiral cells (or vermiform bodies) only by dimension, so that there is a constant transition from the latter into the former. Both are quite as frequently filled with sap (in the youngest portions of the plant) as with air (in the full-sized organs). They are first perceptible in the bud. The spiral vessels of the wood are to be distinguished from those of herbaceous plants, both as regards their origin and their function. The latter has not yet been fully explained, owing to the diversity of views entertained by different inquirers. Spiral formation begins when the simple cell membrane ceases to exist. This, as well as all other transitions from one form to another, is accompanied by modifications and changes of the chemical constituents of the vegetable body. In some cases the air in the cavities of the plant contains more oxygen than the atmospheric.

AIRY, George Biddell, astronomer royal of England, born at Alnwick, July 27, 1801. He was a fellow of St. John's college, Cambridge, and afterward of Trinity. He was appointed Plummerian professor of astronomy at Cambridge in 1828, and annually published the results of his investigations at the observatory there (9 vols. 4to, 1829–38). On the retirement of Mr. John Pond in 1835, he became astronomer royal, which office he continues to hold (1872). He is president of the astronomical society, and in 1871 was elected president of the royal society. He distinguished himself by the publication of the long-neglected observations at Greenwich of the moon and planets from 1750 to 1830. His labors are regarded as having opened a new epoch in planetary astronomy. He has acquired high reputation by his researches into the mode of simplifying the theory of planetary perturbation, by his contrivance of a new instrument for observing the moon off the meridian, and substituting for the old mural circle and transit instrument another of simple construction and of great utility. In 1854 he corrected certain erroneous impressions which prevailed touching the variations of the compass in ironclads. In 1859 his memorable researches on the motion of the solar system in space were first announced. He prepared the formula and methods for conducting the survey of the Maine boundary between Canada and the United States. He observed eclipses of the sun at Turin (1842), at Gothenburg (1857), and in Spain (1860). His important contributions to astronomy, magnetism, meteorology, photography, and other sciences are contained in leading English cyclopædias and in the annals of learned socie-

ties. In his "Essays on the Invasion of Britain by Julius Caesar" (London, 1865), Prof. Airy questions the accuracy of D'Anville's, Rennel's, and Halley's theories about the points of Caesar's sailing and landing; he regards the points of departure to have been so far from Calais as the mouth of the Somme, and the place of landing so far from Deal as Pevensey bay.

AISNE, a department in the north of France which takes its name from the river Aisne, an affluent of the Oise. It consists of portions of Ile de France, Brie, and Picardy, and is bounded by the departments of Le Nord, Ardennes, Marne, Seine-et-Marne, Oise, and Somme, and Belgium. Area, 2,838 sq. m.; pop. in 1872, 552,439. It is traversed by the Oise, Aisne, Oureq, and Marne. The surface is mostly flat, and the soil fertile. It is divided into the arrondissements of St. Quentin, Laon, Château-Thierry, Soissons, and Vervins. Capital, Laon. The quantity of farm produce and live stock exceeds that of most parts of France. A profitable trade is carried on in pressing oil from the beech mast of the extensive forests. Several of the towns are noted for their manufactures. The mirrors of St. Gobain are known throughout France.

AISSE, Mlle., a Circassian lady, born in 1694, died in Paris in 1733. When she was four years old the count de Ferriol, French ambassador at Constantinople, purchased her from a slave dealer, who stated that she was the daughter of a Circassian prince. The count had her educated at Paris, under the superintendence of his sister-in-law, but he afterward seduced her. Though she repulsed the brilliant offers of the dissolute regent, the duke of Orleans, she indulged a guilty passion for the chevalier d'Aydie, a knight of Malta. Her letters contained interesting anecdotes relating to the court and to contemporary personages, and were thought worthy by Voltaire of being published, accompanied by annotations of his own. (1787). In 1806 they were collected, together with those of Mmes. de Villars, La Fayette, and De Tencin (Paris, 3 vols. 12mo).

AITKIN, a new county of E. Minnesota; area, about 950 sq. m.; pop. in 1870, 178. Part of Lake Mille Laes occupies its W. corner. The route of the Northern Pacific railroad extends through the N. part of the county.

AITON, William, a Scotch gardener and botanist, born near Hamilton in 1731, died at Kew palace, Feb. 1, 1793. He emigrated to England in 1754, and in 1759 obtained the management of the royal botanical garden at Kew, and in 1783 also that of the pleasure garden. Under his care Kew gardens became the principal scene of botanical culture in the kingdom. In 1789 he published his *Hortus Kewensis* (3 vols. 8vo), in which 5,600 species are described. The system of arrangement adopted is the Linnean, and the author indicates the origin, mode of culture, and the epoch of introduction into England, of each species. He

was assisted in this task by two learned Swedes, Dr. Solander and Mr. Jonas Dryander. He was succeeded by his son, WILLIAM TOWNSEND AITON, who retired in 1841, and died in 1849, aged 84.

AITZEMA, Lienwe van, a Dutch historian, born at Dokkum, Nov. 19, 1600, died at the Hague, Feb. 23, 1669. His great work is *Zaaken van Staat en Oorlog in Ende omtrent de Vereenigde Nederlanden* (14 vols. 4to, 1657-'71; 7 vols., 1669-'72). It is chiefly valuable on account of the numerous original documents, referring to the period 1621-'68, which it contains. Aitzema was actively engaged in political affairs, and in his latter years was agent of the Hanseatic towns at the Hague.

AIX, a town of southern France, department of Bouches-du-Rhône, 15 m. N. of Marseilles; pop. in 1866, 28,152. It is the see of an archbishop, and possesses a museum and one of the best provincial libraries of France, containing 100,000 volumes. It was the *Aque Sextie* of the Romans, so called on account of its thermal springs by Sextius Calvinus, who founded it after a victory achieved there over the Gauls, 123 B. C. Between Aix and Arles is the battle field on which Marius gained his great victory over the Teutons, 102 B. C. The counts of Provence made Aix their capital. The town is handsome, and adorned with a beautiful promenade. The cathedral, the clock tower in the market place, containing a curious clock, and the hôtel de ville, are fine specimens of middle-age architecture. The mineral baths are but little frequented; they are impregnated with sulphur, and are said to soften and improve the skin.

AIX-LA-CHAPELLE (Ger. *Aachen*), a town of Rhenish Prussia, capital of the administrative district of the same name, 43 m. by railway W. S. W. of Cologne; pop. in 1871, 74,238. It is pleasantly situated on rising ground, is a centre for Rhenish industry, and is the focus of an important net of railways connecting Belgium, Holland, and Germany. The annual export of cloth to the United States amounts to about \$1,500,000. The Aachen-Munich fire insurance company and the savings bank are the greatest enterprises of the kind in Germany. The value of mineral products furnished by one of the joint-stock companies amounted in 1869 to 2,491,000 thalers. Railroad iron is manufactured to a very large amount, and there are also flourishing manufactures of woollens, silks, hosiery, shawls, buttons, clocks, pins, railway and other carriages, tobacco, and cigars. A polytechnic school for the Rhenish provinces and for Westphalia was opened Oct. 10, 1870. The town is handsomely built, and contains a fine Gothic town house, and a beautiful cathedral, in which is the tomb of Charlemagne, who made this his favorite residence. A collection of famous relics, presented to Charlemagne by the patriarch of Jerusalem and the caliph Haroun-al-Rashid, is kept in a tower at the west end of the cathedral, and exposed to

public view once in seven years. Until 1558 all the German emperors were crowned here, and their portraits, together with Charlemagne's chair and many other interesting historical memorials, are preserved either in the cathedral or in the town hall. The imperial insignia were removed to Vienna in 1793. The burghers enjoyed rare exemptions and privileges until the reformation, which was warmly espoused by the citizens. After desperate contests, however, the Catholics, with the aid of Spanish soldiery from the Netherlands, suppressed Protestantism, and the privileges were taken away from the city. The population is now Catholic, excepting about 3,000 Protestants and 400 Jews. A magnificent monument in commemoration of the warriors of 1866, by Friedrich Drake, was inaugurated in 1872.—Aix-la-Chapelle is renowned for its mineral baths, which were known to the Romans, by whom the place was called *Aquisgranum*, either from an epithet of Apollo, to whom thermal springs were sacred, or from Severus Granius, a Roman commander about A. D. 125. The waters contain sulphur, and have a heat of 131° F. They are very beneficial in skin and paralytic affections. In the suburb of Borette (*Burtscheid*) there are also springs, both hot and cold, which are not impregnated with sulphur.—**Treaty of, 1668.** At the death of Philip IV. of Spain, 1665, Louis XIV., his son-in-law, asserting a claim to parts of the Spanish dominions in right of his wife, Maria Theresa, under the Brabant laws of devolution, commenced the war of succession and seized the province of Franche-Comté, together with several fortresses and strongholds in the Netherlands. The Spaniards were unable to make head against such commanders as Condé and Turenne, and Holland, alarmed at the progress of the French, concluded the triple alliance with England and Sweden. Louis accepted mediation in preference to the alternative of arms, and a congress at Aix-la-Chapelle ended in a treaty, May 2, 1668, by which Franche-Comté was restored to Spain, but several of the strong towns in the Netherlands, including Lille and Valenciennes, were retained by France.—**Treaty of, 1748.** The Austrian war of succession had arisen from the claims raised by several German princes in opposition to Maria Theresa, who succeeded to the throne of her father, Charles VI., in virtue of the pragmatic sanction. The war lasted from 1740 to 1747, and almost all the powers in Europe were engaged on one side or the other—England and France being, as usual, opponents. The preliminaries were signed in April, 1748, and ratified in October. The pragmatic sanction was renewed, and the *status quo ante bellum* of most of the parties restored. Frederick the Great remained in possession of Silesia, which he had conquered. Austria ceded, besides, to Sardinia, some portions of the Milanese territory; and to Philip, the brother of the king of Spain, Parma, Piacenza, and Guas-

talla.—**The Congress of Aix-la-Chapelle (1818)** was held for the purpose of settling outstanding questions incident to the wars concluded by the treaties of Vienna. It was attended by the emperors of Austria and Russia and the king of Prussia in person, and by the representatives of the allied powers, Prince Metternich, Lord Castlereagh, the duke of Wellington, Counts Hardenberg, Bernstorff, Nesselrode, and Capo d'Istria. France, being invited to cooperate, sent the duke de Richelieu. The conferences resulted in declarations by the powers confirmatory of the principles of the holy alliance, in a circular to that effect to all the minor courts of Europe, and in freeing France from the allied army, which had remained in that country for nearly three years.

AIX-LES-BAINS, or **Aix** (anc. *Aqua Allobrogum*, *A. Gratiana*, or *A. Domitiana*), a bathing place of S. E. France, in the department of Savoie, 8 m. N. of Chambéry; pop. in 1866, 4,430. The waters are warm, impregnated with sulphur, and have a temperature of from 112° to 117° F. West of it is the lake of Bourget.

AIZANI, or **Azani**, an ancient city of Asia Minor, in Phrygia, mentioned by Strabo, but historically unknown. Its numerous remains at Telavdyr, 30 m. S. W. of Kintaieh, have been described by several travellers since their discovery by the earl of Ashburnham in 1824. They comprise an ancient temple of Jupiter, a theatre, stadium, and gymnasium. The theatre is in fine preservation. Its greatest diameter was 185 feet, and the auditorium had 15 rows of marble seats. The river Rhyndaes (now Adranas) rises near the town and passes through it, and was spanned by two bridges of white marble, each consisting of five semicircular arches. There are besides many tombs, and Roman coins and inscriptions have been found.—See Hamilton's "Researches in Asia Minor," and Sir C. Fellows's "Asia Minor."

AJACCIO, capital of the island and French department of Corsica, a seaport on the W.

Birthplace of Napoleon Bonaparte.

coast, in lat. $41^{\circ} 55' N.$, lon. $8^{\circ} 44' E.$; pop. in 1866, 14,558. It has a cathedral, college, museum, library, botanical garden, naval school, picture gallery presented to the town by Cardinal Fesch, and fine promenades. It is much frequented in winter by invalids on account of its genial climate, and is connected by steamers with Marseilles and Nice. The largest ships can lie along its wharves, but the harbor is dangerous during the prevalence of southwest winds. Wine, olive oil, and fruits are the chief articles of trade. It is the birthplace of Napoleon Bonaparte, and the house in which he was born is still in good preservation.

AJALON, or *Ajalon*, a town of ancient Palestine, about 14 m. N. E. of Jerusalem, allotted to the tribe of Dan, but also spoken of as belonging to Ephraim, to Benjamin, and to Judah. It was of little historical importance, and is chiefly known as the place near which, according to the narrative originally contained in the book of Jasher, Joshua commanded the moon to stand still. The modern town is called Yalo.

AJAN, an extensive tract on the E. coast of Africa. It extends from Zanguebar to Cape Guardafui, about 10 degrees of latitude, the southern extremity being near the equator. The S. coast is sandy and barren; the N. is high, especially at Cape d'Orfui (Ras Hafoon), which is a bluff toward the sea, backed by lofty mountains of singular shape. The inhabitants belong to the Eesah or Somauli tribe. There is no river of importance. Ajan was known to the ancients, and called Azania. The inhabitants traded with the Arabs in ivory, tortoise shell, &c., and were under Arab control; and Rhaptum, the capital, was the furthest point to the south known to the Greeks.

AJAX, the name of two Greek chiefs in the Trojan war, distinguished as the greater and the lesser. The greater was the son of Telamon, king of Salamis, and third in direct male descent from Jupiter. He was second only to Achilles in martial prowess, equal to him in strength, but inferior in agility. He led the forces of the Salaminians, in 12 ships. Hector retired before the Telamonian Ajax on more than one occasion in the course of the war. At the death of Achilles, the arms of that hero were allotted to him who had deserved best of the Greeks. But two advanced claims to this honor, the greater Ajax and Ulysses. The former alleged his preëminence as a warrior, the latter as a counsellor. The arms were adjudged to Ulysses. Ajax went mad, committed many excesses, and slew himself. This catastrophe, which is only alluded to by Homer, forms the subject of the tragedy of Sophocles called the "Ajax." In the *Odyssey*, Ulysses is represented as descending to the infernal regions and there making fraternal overtures to Ajax, who stalks away without reply. He was worshipped in Salamis as its tutelary hero.—The lesser, son of Oileus, king of the Locrians, whom he led in 40 ships, was remarkable for his swiftness of foot. Having excited the an-

ger of the gods, they raised a storm against his fleet as he was returning home. The Oilean escaped to a rock, and defied the vengeance of the gods, whereupon Neptune cleft the rock with his trident, and threw Ajax into the sea. His fate is, however, variously told by the poets. According to some, his crime was the violation of Cassandra in the temple of Minerva, at the sack of Troy.

AJMEER, or *Ajmere*. **I.** A non-regulation district of Rajpootana, subject to the lieutenant governor of the Northwest Provinces of Bengal, between lat. $25^{\circ} 43'$ and $26^{\circ} 42' N.$, and lon. $74^{\circ} 22'$ and $75^{\circ} 33' E.$; area, 2,029 sq. m.; pop. 225,000, mostly Hindoos. The N. W. portion is occupied by mountains connected with the Aravulli range, and contains mines of carbonate of lead, and ores of manganese, copper, and iron. Elsewhere the country is sandy and nearly level. The only river, the Korie, is so strongly impregnated with carbonate of soda that the water is undrinkable. **II.** A city, capital of the above district, situated on the slope of a rocky basin in lat. $26^{\circ} 29' N.$, lon. $74^{\circ} 43' E.$, 220 m. S. W. of Delhi; pop. about 30,000. It is an ancient city, with stone walls and fine gateways, spacious houses, numerous temples, and a ruined palace of Shah Jehan. A large artificial lake supplies it with water. It has an annual fair and pilgrimage in honor of a Mussulman saint called Kwajah, who is supposed on these occasions to work extraordinary miracles. In the 16th century it was the chief place of one of Akbar's richest provinces. The British took it from the Sindia family in 1817.

AKABAH, a fortified village of Arabia, situated in an extensive date grove, or oasis, near the northern extremity of the gulf of Akabah. It is believed to occupy the site of either the Scriptural Elath (the *Elana* of the Greeks) or Eziongeber. (See *ELATH*).—*Gulf of* (the *Elanitic* gulf of the ancients), an inlet of the Red sea, about 12 m. wide, forming its N. E. arm after its bifurcation, lat. $28^{\circ} N.$ It extends in a N. E. direction to lat. $29^{\circ} 32' N.$, bounding the mountainous peninsula of Sinai on the E.

AKBAR, or *Akber*, *Jelal-ed-Deen Mohammed*, the greatest of all the Mogul emperors of Hindostan, born Oct. 14, 1542, died in September, 1605, after reigning half a century. At the time of his accession to the throne of Delhi, on the death of his father Humayun, his dominions embraced but three provinces; in the 40th year of his reign they numbered 15, embracing the whole of Hindostan N. of the Deccan. Akbar was tolerant of all forms of religious belief, and invited Portuguese missionaries from Goa to give him an account of Christianity, which, however, he did not adopt. He diminished the cruel and oppressive taxes laid on his Hindoo subjects, reformed the administration of the revenue, promoted commerce, and improved the roads of the empire. He encouraged learning and literature, and instituted schools in all parts of his empire. His history

was written in Persian by his vizier, Abul Fazl, under the title *Akbar Nameh*, partly translated into English ("Ayeen Akbery, or the Institutes of Akber," 3 vols. 4to, Calcutta, 1783-'6, and London, 1800).

AKENSIDE, Mark, an English physician and poet, born in Newcastle-upon-Tyne, Nov. 9, 1721, died in London, June 23, 1770. He was the son of a butcher, and was injured for life when very young by his father's cleaver falling upon him. He was educated for a Presbyterian clergyman, beginning his studies at an academy in Newcastle, and continuing them at the university of Edinburgh. While here he decided to become a physician, and devoted the last two years of his course to medical education. In 1742 he went to Leyden, where he took his degree of M. D. in May, 1744. Just before this he had published in London his poem "The Pleasures of Imagination." Even at an earlier age he had written verses for magazines. The "Pleasures of Imagination" achieved immediate and marked success. It was especially praised by Pope. Akenside practised first at Northampton, but afterward went to London. He was at this time assisted by a friend, Jeremiah Dyson, a lord of the treasury, who gave him an allowance of £300 a year until his practice should support him. He was made a fellow of the college of surgeons and a physician to the queen, but attained no great success in the ordinary walks of his profession. Besides the "Pleasures of Imagination," his greatest work, he wrote several minor poems, and a large number of professional pamphlets and essays.

ÅKERBLAD, Johan David, a Swedish philologist, especially skilled in oriental languages, born in 1760, died in Rome in 1819. When a young man he was made an attaché of the Swedish embassy to Constantinople, where he found an excellent opportunity for the study of Turkish. In 1795 he was made secretary of the embassy, but in 1797 devoted himself to study for a time, and for this visited Göttingen in 1800. In 1802 he was appointed secretary of the embassy at the Hague, and in 1803 chargé d'affaires at Paris. While in Paris he found some Coptic MSS. in the national library, and discovered the key to the unknown character in which they were written. In 1804 he left the Swedish service and went to Rome, where the duchess of Devonshire and others gave him the means of pursuing his studies during the remainder of his life. His works relate chiefly to oriental inscriptions.

AKERMAN, or **Akjerman** (Gr. *Monkastron*; anc. *Tyras*), a town in Bessarabia, on the estuary of the Dniester, near its mouth in the Black sea, and 35 m. S. W. of Odessa; pop. in 1869, 29,373. It is situated at the foot of a rock crowned by a citadel, has a good harbor, and carries on an extensive trade in salt. The interior, in general, has a Turkish aspect. The population, about half Europeans, is greatly mixed. Akerman is the capital of a dis-

trict of the same name, which has 21 German settlements.

AKERS, Benjamin Paul, an American sculptor, born in Saccarappa, near Portland, Me., July 10, 1825, died in Philadelphia, May 21, 1861. At the age of 18 he went to Portland. After working for some time in a printing office, he was induced to study sculpture. In 1849 he opened a studio in Portland, and during the next two years modelled busts of Henry W. Longfellow and others. In 1851-'2 he visited Italy, and upon returning to Portland modelled a statue of "Benjamin in Egypt," which was exhibited at the New York crystal palace in 1853. In January, 1855, he sailed again for Europe, and during a residence of three years in Rome produced the best of his works, "Una and the Lion," a statue of St. Elizabeth of Hungary (of which three repetitions in marble were executed), the "Dead Pearl Diver," exhibited in the United States, and an ideal head of Milton. The last two works are elaborately described in Hawthorne's "Marble Faun." After returning to America in impaired health, in 1859 he revisited Rome, returned home in 1860, and lived in Portland and Philadelphia.

AKHALTZIKH, Akhalzikh, Achalzik, or Akhyskha, a strongly fortified town of Transcaucasian Russia, in the government of Kutais, on an affluent of the Kur, about 95 m. W. of Tiflis; pop. in 1869, 11,616, two thirds Armenians. It has a castle, a fine mosque containing a rich oriental library, several churches, and a synagogue, and is the seat of a Greek archbishopric. It is situated in an elevated valley, in an Armenian district which was ceded by the Porte to Russia in the peace of Adrianople (1829).

AKHISSAR, or Ek-Hissar (anc. *Thyatira*), a town of Asia Minor, in the eyalet of Aidin, 58 m. N. E. of Smyrna; pop. about 12,000. It is built on somewhat elevated ground, and contains about 1,000 Turkish, 300 Greek, and 30 Armenian dwellings.

AKHLAT, a town of Asiatic Turkey, in the eyalet of Van, at the base of the Sipan Dagh, on the W. shore of Lake Van; pop. about 5,000. Near it are the magnificent ruins of an ancient residence of the Armenian kings. It is the see of an Armenian bishop.

AKHTYRKA, or Achtyrka, a town of Russia, in the government and 60 m. W. N. W. of Khar-kov; pop. in 1866, 17,544. It is situated on three lakes, has many manufactures, and ten churches, one of which attracts numerous pilgrims by a miraculous image of the Virgin.

AKIBA BEN JOSEPH, a Jewish rabbi of the early part of the 2d century, one of the principal fathers of the Mishna. A native of Syria, he travelled in Arabia, Gaul, Cyrene, Egypt, and other countries, and became the most eminent teacher of his time and people. Having warmly embraced the cause of the insurrection under Bar Cokheba against the Romans, he was captured and executed about 135.

AKMOLINSK, a province of Siberia, organized by a ukase of Oct. 21 (Nov. 2), 1868. It is

composed of Kokchetav, Atbassar, and Akmolinsk (three of the five districts into which the land of the Siberian Kirghiz was formerly divided), of five districts and part of a sixth of the Siberian Cossacks, and of the towns of Omsk and Petropavlovsk. Capital, Akmolinsk, 300 m. S. W. of Omsk, founded by the Russians in 1862; pop. in 1867, 4,800. The province remains under the governor general of Western Siberia.

AKRON, a city and the capital of Summit county, Ohio, 36 m. S. of Cleveland, at the junction of the Ohio and Erie and Ohio and Pennsylvania canals, and at the intersection of the Atlantic and Great Western and the Cleveland, Mt. Vernon, and Delaware railways; pop. in 1860, 3,477; in 1870, 10,006. The canals and the Little Cuyahoga river furnish ample water power for numerous mills, factories, and other mechanical establishments. The chief articles of manufacture are flour and woollen goods. There is also a steam engine factory, a blast furnace, a mineral paint mill, a card manufactory, and an extensive stove manufactory. The town is 400 feet above the lake, being the most elevated ground on the line of the canal between Lake Erie and the Ohio river. In the vicinity of the town immense beds of Ohio mineral fire-proof paint are found, and exported to every part of the country. Akron was first settled in 1825.

AK-SHEHR (the White City), a town in the eyalet of Karaman, in Asia Minor, about 5 m. S. of a lake of the same name, and 65 m. N. W. of Konieh; pop. about 15,000. It is the seat of a pasha, and a station of considerable importance on the caravan route between Constantinople and Syria. It carries on an extensive trade, and manufactures carpets, &c. Ak-Shehr is the Philomelium of the ancient geographer Strabo, and near it the German emperor Frederick I. fought a battle with the Seljuks in 1190. It was afterward called Aksiari. Here also the sultan Bajazet I., who was a prisoner in the fortified camp of Tamerlane, died in March, 1403.

AKSU, or **Oksu**, a commercial and manufacturing town of East Turkistan, about 250 m. N. E. of Cashgar; pop. estimated at about 50,000. It is situated in a fertile valley at the terminus of a road leading across the Thian Shan mountains to the Sungarian district of Ili, with which it has an extensive trade. Russian, Tartar, and Chinese caravans here effect their exchanges, and there are famous manufactures of a sort of unglazed cotton cloth called *bias*, elaborate saddlery of deer-skin, and jewelled and jasper ornaments. While East Turkistan was under Chinese rule, the city had a Chinese garrison of 2,000 or 3,000 men. The inhabitants are industrious and hospitable. Aksu was the capital of the kings of Cashgar and Yarkand. In 1716 it was nearly destroyed by an earthquake, and at the beginning of the present century it was swept by a freshet in which 3,000 persons perished.

AKYAB, a town of British Burmah, capital of the province of Aracan, situated in lat. 20° 8' N., lon. 92° 54' E., on the E. side of the island of Akyab, at the mouth of the Aracan river, 50 m. S. S. W. of the town of Aracan, the former capital; pop. in 1864, 15,512. Its origin dates from 1826. The houses are built chiefly of bamboo; the streets are broad; there are several public buildings and barracks, besides the British government house. It is a free port, opium being the only article subject to duty. The harbor is safe, and the coasting and foreign trade extremely active. It is an important Protestant missionary station.

AL, il, or **ul** (improperly pronounced by those of other nations *el*), the Arabic definite article, and indeed the only article in use in the Arabic language, words indefinitely used standing alone, as *yad*, a hand, *al* or *il yad*, the hand. When this article stands before a lingual or dental (of which there are in Arabic 13, called *shamsi*), the sound of the letter *l* (*lam*) is dropped for the sake of euphony, and the initial dental or lingual takes a double sound; thus, *il shams*, the sun, is pronounced *ish shams*. When the word preceding the article ends in a long vowel, a *wasla* (marked thus ~) is placed over the *a* (*alif*), indicating that it is to be dropped in pronunciation, and the *l* joined to the vowel sound. Thus, Abu il Feda is pronounced Abulfeda.

ALABAMA (Indian, "Here we rest"), one of the southern states of the American Union, situated between lat. 30° 10' and 35° N., and lon. 84° 53' and 88° 30' W., bounded N. by Tennessee, E. by Georgia and Florida, S. by Florida and the gulf of Mexico, and W. by Mississippi; area, 50,722 sq. m. Alabama is divided into 65 counties, viz.: Autauga, Baker, Baldwin, Barbour, Bibb, Blount, Bullock, Butler, Calhoun, Chambers, Cherokee, Choctaw, Clarke, Clay, Cleburne, Coffee, Colbert, Conecuh, Coosa, Covington, Crenshaw, Dale, Dallas, De Kalb, Elmore, Escambia, Etowah, Fayette, Franklin, Geneva, Greene, Hale, Henry, Jackson, Jefferson, Lauderdale, Lawrence, Lee, Limestone, Lowndes, Macon, Madison, Marengo, Marion, Marshall, Mobile, Monroe, Montgomery, Morgan, Perry, Pickens, Pike, Randolph, Russell, Sanford, Shelby, St. Clair, Sumter, Talladega, Tallapoosa, Tuscaloosa,

State Seal of Alabama.

Walker, Washington, Wilcox, and Winston. There are eight cities in the state. Mobile, on the Mobile river, near its mouth in the bay of the same name, is the first in size and commercial importance, having a population in 1870 of 32,034. It is one of the most important ports on the gulf of Mexico, being the natural outlet for S. Alabama and S. E. Mississippi, and ranks next to New Orleans and Savannah in extent of cotton exports. The other cities are Montgomery, the capital, on the Alabama river (pop. 10,588), Selma (6,484), Huntsville (4,907), Eufaula (3,185), Talladega (1,933), Tuscaloosa (1,689), and Tuscombina (1,214). The more important towns are Greenville (pop. 2,856), Marion (2,646), Florence (2,003), Grantville (1,761), Greensboro (1,760), Union Springs (1,455), La Fayette (1,382), Prattville (1,346), Wetumpka (1,137), Auburn (1,018), and Athens, Jacksonville, and Decatur, with populations less than 1,000. The following table shows the population of the state at each census since its admission into the Union:

Census.	Whites.	Fr. colored.	Slaves.	Total.
1820....	85,451	571	41,879	127,901
1830....	190,406	1,572	117,549	309,527
1840....	335,185	2,639	253,536	590,753
1850....	426,514	2,265	342,844	771,623
1860....	526,271	2,690	435,080	964,201
1870....	521,384	475,510	996,894

In 1866 the total population was 946,244, classified as follows: whites, 522,799, of whom 257,337 were males and 265,462 females; colored, 423,445, of whom 206,505 were males and 216,940 females. By the federal census of 1870, Alabama ranks 16th in population among the states. Of the whole number of inhabitants, 987,030 are native and 9,962 foreign born; of the former, 744,146 were born in the state. The gain in the total population during the decade between 1860 and 1870 was 3.40 per cent. There was a gain of 8.62 per cent. in the colored population, but a loss of 0.93 in the white. The effect of emancipation, by adding the two fifths of the slave population formerly excluded from the basis of representation, has been to add 23.40 per cent. to the representative population, of which the total gain has been 26.17 per cent. The whole number of male citizens 21 years of age and upward is 202,182. The number of Indians is 98. In 1860 the number of deaths resulting from unknown causes was 1,608, or 16.67 per cent.; in 1870, 730, or 7.21 per cent.—The Alleghany mountains exhaust themselves in N. E. Alabama, rendering that portion of the state uneven and broken, though the elevation is nowhere very great. The range extends W. with a slight bend to the S., and forms the dividing line between the waters of the Tennessee and the other rivers of Alabama, all of the latter ultimately flowing southward into the gulf of Mexico. From this range the face of the country slopes to the S., and is somewhat uneven as far as the centre of the state, where we find rolling

prairies, pine barrens, and very fertile alluvial bottoms. The extreme southern portion of the state is flat, and but slightly elevated above the level of the gulf of Mexico.—Alabama may be divided into five regions, viz.: the timber region, containing 11,000 sq. m.; the cotton region, 11,500; the agricultural and manufacturing region, 8,700; the mineral region, 15,200; and the stock and agricultural region, 4,322. The timber region, bordering on the gulf of Mexico and Florida, extends across the S. portion of the state and 40 m. N. from the Florida line. This section, covered with forests of long leaf yellow pine, yields excellent timber, tar, pitch, and turpentine. The state also produces in abundance different varieties of oak, bald and black cypress, the timber of which is remarkable for its durability, sweet and black gum, poplar, ash, walnut, hickory, locust, chestnut, red and white cedar, dogwood, maple, and elm. Groves of cedar of great height abound in the canebrakes of Marengo and Greene counties. Below the 33d parallel commences the long moss region. This moss, which hangs in festoons from the trees so extensively as to darken the forest, is much used for mattresses. The cotton region joins the timber region on the north, and has a width of about 102 m. on the W. and 60 m. on the E. line of the state. This belt of land, interspersed with large prairies, with an unsurpassed climate and having a stiff black soil, remarkably rich, and from 2 to 20 feet deep, is considered one of the most fertile and healthy agricultural tracts in the South. The land will produce from 50 to 60 bushels of corn or 800 to 900 pounds of seed cotton per acre. Immediately N. of the cotton region lies the agricultural and manufacturing district, extending E. and W. across the state, and having an average breadth of about 35 m. The soil is sandy and poor, but there are numerous streams affording water power. The mineral region occupies the N. E. corner of the state, extending S. W. about 160 m., and has an average width of about 80 m. White marble of remarkable brilliancy, soapstone, flagstones, graphite or plumbago, and granite of good quality are obtained here. In this region are three distinct coal fields, covering an area of 4,000 sq. m., and containing bituminous coal in beds from 1 to 8 feet thick. Near these coal fields are extensive beds of limestone, sandstone, and iron ore producing from 36 to 58 per cent. of metallic iron. Red and other ochres are found; galena and manganese exist in the limestone formations. The stock and agricultural region occupies the N. W. portion of the state; its productions are cotton, corn, grain, grapes, and stock.—Alabama has only about 60 m. of sea-coast, extending from Perdido to the W. line of the state, a large portion of the S. boundary being cut off from the gulf by an intervening strip of Florida. Mobile bay, the great outlet to the navigable waters of the state, is the largest

and finest on the gulf, being 30 m. in length and from 3 to 18 m. in breadth, with 22 feet of water at the main entrance at low tide; but the channel for 10 m. below Mobile is not more than 8 or 9 feet deep at low tide. Perdido bay is of slight importance. About two thirds of the counties of the state are bounded or intersected by navigable rivers, the principal of which are the Mobile, Alabama, Tombigbee, Chattahoochee, Coosa, and Tennessee. The last named comes in at the N. E. corner of the state, and taking a circular sweep southward goes out at the N. W. corner, and empties into the Ohio at Paducah, Ky. Its continuous navigation is interrupted by Muscle Shoals, near Florence. The great river of the state is the Mobile, formed by the confluence of the Alabama and Tombigbee about 50 m. above Mobile bay, into which it empties at Mobile. The Tombigbee rises in N. E. Mississippi, and is navigable for light-draught steamers to Columbus, about 300 m., and for flat-boats about 125 m. further. The Black Warrior, a branch of the Tombigbee, has its source in N. Alabama, empties near Demopolis, and is navigable for steamers to Tuscaloosa, 285 m. from Mobile. During freshets the Black Warrior at Tuscaloosa rises to a height of 50 feet. The Alabama, which is the eastern branch of the Mobile, is navigable to Montgomery, about 320 m. The Coosa, a branch of the Alabama, is navigable from its mouth to Wetumpka, and from Greensport to Rome, Ga., altogether 160 m., while its course between Wetumpka and Greensport for 180 m. is obstructed by shoals. The Chattahoochee, a large river rising in Georgia and emptying into Appalachicola bay, forms the eastern boundary of Alabama for more than 100 m. It is about 500 m. long, and navigable to the falls at Columbus, Ga., 300 m. above its mouth. Among the smaller rivers are the Conecuh, emptying into the Escambia; the Perdido, emptying into Perdido bay; the Choctawhatchee, emptying into the bay of the same name; and the Cahawba and Tallapoosa, affluents of the Alabama. The attention of the general government and the states interested has been directed to the improvement of the Tennessee and Coosa rivers, and their connection by a canal, in order to form an outlet for the produce of the northwestern and southern states, which will possess advantages over that by the Mississippi river.—Among the natural curiosities are: a natural bridge in Walker county; Bladen and Blount springs, which are the resorts of health and pleasure seekers; and the sulphur springs of Talladega county. The remains of various mounds and roads have been found in different parts of the state, of which the Indians formerly occupying the country furnish no traditions. A stream of water issues from a large fissure in the limestone rocks at Tusculumbia, which is said to discharge 125 lhd. of water per minute, forming a considerable river which empties into the Tennessee. The N. E. corner of the state abounds in wild,

grand, and picturesque scenery. The "Snek," a sort of maelstrom in the Tennessee river, and Paint Rock, a very high bluff with figures representing a man's face, are objects of much curiosity.—The climate of Alabama is healthy, except on the low river bottoms, where the prevailing diseases are intermittent, congestive, and bilious fevers; congestive fevers being the most fatal. According to the census of 1870 the rate of mortality was about one death to every 93 inhabitants. Mobile, in its early history, was several times severely ravaged by yellow fever. In the elevated portions of the country the climate is delightful, the heat of summer being materially mitigated by the gulf breezes. During summer the mercury ranges from 104° to 60° F.; in November and the winter months, from 82° to 18°; and in spring, from 93° to 22°. The mean temperature of the state is about 63°, or perhaps something less, and the mercury seldom rises above 95°. July is the hottest month in the year. The fall of rain for 1870 was 48.53 inches. Very little snow falls, and the rivers are never frozen over, though stagnant water is sometimes covered with a thin coating of ice. Fruit trees blossom from the 1st of February to the 1st of March, according to the elevation. In the lower portion of the country there is almost a total lack of good water, while that found in the higher regions is very good. In many parts of the state the inhabitants procure their water from artesian wells, which not unfrequently reach a depth of 1,000 feet, and some of them throw up water in sufficient quantity to turn mills and other machinery.—The soil of the state is various, but mainly productive. In the southern part there are considerable tracts of sandy barrens, but the river bottoms are remarkably fertile. Some portions of the highlands in the north are not worth cultivating, while by far the greater portion is very excellent land, having a productive soil of variable depth, resting on a limestone bed. By its great advantages of soil and climate, Alabama has always held a high rank as an agricultural state. Agriculture forms the principal occupation of the people, manufacturing being carried on only to a limited extent. The chief productions are cotton and Indian corn, though other grains are raised, as are also sugar cane and rice on the bottom lands in the extreme south; and tobacco is grown to a small extent. According to the census of 1870, there are 4,982,340 acres of improved land in the state, and 9,491,270 of unimproved, of which 8,034,700 acres are woodland. The assessed value of real estate is \$117,223,043, and of personal property \$38,359,552; true value of all real and personal property, \$201,855,841; cash value of farms, \$67,502,433; of farming implements and machinery, \$3,256,101; of all live stock, \$26,077,267; of home manufactures, \$1,083,720; of slaughtered animals, \$4,556,467; estimated value of all farm products, including betterments and additions to stock, \$66,532,810; total amount of wages paid to agricultural

laborers during the year, including value of board, \$11,791,191. The productions were 423,312 bales of cotton, 16,660,488 bushels of Indian corn, 1,049,960 of wheat, 18,594 of rye, 767,732 of oats, 152,456 of peas and beans, 157,446 of Irish and 1,806,264 of sweet potatoes, 222,943 lbs. of rice, 151,557 of tobacco, 370,773 of wool, 3,178,638 of butter, 21,068 of wax, 307,706 of honey, 10,553 tons of hay, and 166,009 gallons of cane and 261,986 of sorghum molasses. There were 78,962 horses, 75,644 mules and asses, 165,663 milch cows, 57,237 working oxen, 248,943 other cattle, 234,607 sheep, and 701,346 swine. The number of manufacturing establishments in the state was 2,231, employing \$5,713,607 capital, 291 steam engines with 7,640 horse power, 736 water wheels with 11,098 horse power, and 8,349 hands, receiving \$2,211,638 wages annually. The value of materials used in 1870 was \$7,643,784, and of products, \$13,220,655. Of the manufactories, the most important are 33 for ginning cotton, 10 for the manufacture of cotton goods, 3 for cotton thread and yarn, 20 for the manufacture and working of iron in various forms, 143 for leather, 13 for machinery, 284 lumber mills, and 613 flour and grist mills.—The foreign commerce of Alabama all centres at Mobile, where cotton is the chief article of export, though considerable quantities of sawed lumber and staves are shipped to Cuba, and cedar railroad ties to the northern states. The exports to foreign countries from Mobile for 1870 were \$22,422,631, of which \$11,829,786 was taken in American, and \$10,592,845 in foreign bottoms. The imports for the same period were \$1,349,488, of which \$161,499 came in American, and \$1,187,994 in foreign vessels. The exports of cotton were 188,761 bales (94,462,212 lbs.), valued at \$22,376,498. The shipping entering Mobile from foreign ports for 1870 was 40 American vessels, 17,472 tons and 419 men, and 65 foreign vessels, 52,777 tons and 1,320 men. The clearances for foreign ports in the same time were 77 American vessels, 42,663 tons and 889 men, and 51 foreign vessels, 37,075 tons and 976 men. The number of merchant vessels belonging at Mobile in 1870 was 216, with a tonnage of 19,748. During the year 11 vessels, with a total tonnage of 548, were built.—In 1871 there were 1,496 miles of railroad—main and side track—completed in Alabama, with an aggregate assessed value of \$25,943,052 59, as shown in the adjoined table. The Alabama and Chattanooga connects the latter city with Meridian, Miss., by way of Tuscaloosa, and when completed will afford the most direct communication between New York and New Orleans, through East Tennessee. The Memphis and Charleston extends through the northern part of the state, and connects the Mississippi river with the Atlantic. The Mobile and Montgomery extends from Texas, near Mobile, with which it is connected by steamboats, to Montgomery, connecting

at Pollard with the Mobile and Girard road, which is intended to secure direct communication between Columbus, Ga., and Mobile. Running easterly from Montgomery is the Montgomery and Enfaula, which will ultimately form a part of a line to Brunswick on the Georgia seaboard. The Western road, a connecting link of the Mobile, Atlanta, and Augusta line, is completed from West Point via Montgomery to Selma, where by its junction with the Selma and Meridian a continuous line of railroads is formed from Savannah, Ga., to Monroe in Louisiana, from which point connection can be made with the projected Southern Pacific railway. Sixty miles of the Mobile and Ohio road lie in the S. W. part of Alabama; a branch of this road, the Mississippi, Gainesville, and Tuscaloosa, is completed to Gainesville. The Selma, Rome, and Dalton is completed from Dalton, Ga., to Selma, 236 m., and affords a direct outlet to Charleston for the cotton and minerals of central Alabama. The Selma and Gulf line is in process of construction from Selma to Pollard, a distance of 100 m., where connection by railway to Pensacola is made. The Selma, Marion, and Memphis, and the South and North railroads are under construction. The latter connects Montgomery with Decatur, where a junction is made with the Nashville and Decatur road; it will afford an air-line communication between Nashville and the gulf, and serve as an outlet for the mineral stores of central Alabama. An important road is projected from Enfaula to Guntersville, which in the absence of a canal will afford communication between the Coosa and Tennessee rivers. Other projected lines are the Selma and New Orleans, the Mobile and Alabama, Grand Trunk (from Mobile via Marion to Elyton, 240 m.), the Savannah and Memphis, and the Vicksburg and Brunswick. The legislature has empowered the governor, when any railway company incorporated by the state shall have completed and equipped 20 miles of road, to indorse on behalf of the state the first mortgage bonds of the company to the extent of \$16,000 per mile for the portion completed, and \$16,000 for each section of five miles subsequently completed. These liabilities on Sept. 30, 1871, were as follows:

—The present constitution of Alabama was adopted in 1868. The legislative power is vested in a general assembly, consisting of a senate and house of representatives. The latter is composed of not more than 100 members, apportioned among the different counties according to population, but each county is entitled to at least one representative. The present number is 100. The number of senators cannot be more than one third nor less than one fourth that of the representatives. The present number is 33. Senators and representatives are elected on the Tuesday after the first Monday in November, the former for four and the latter for two years. One half of the senators are chosen every two years. Persons qualified as electors to vote for members of the general assembly are eligible as representatives; but senators must have attained the age of 27 years and resided for two years in the state. The general assembly meets annually on the third Monday in November, and cannot remain in session longer than 30 days except by a two-thirds vote of each house. A majority of the whole number of members in each house is sufficient to pass a bill over the governor's veto. The executive department consists of a governor, lieutenant governor, secretary of state, auditor, treasurer, and attorney general, who are elected on the same day as the members of the legislature for a term of two years, except the auditor, who is chosen for four years. The judicial power is vested in a supreme court of three justices, with appellate jurisdiction only, except that it may issue writs of injunction, mandamus, habeas corpus, and quo warranto; five courts of chancery and twelve circuit courts, each of which is held by one judge; a probate court for each county; and city courts for Mobile, Montgomery, Selma, and Huntsville; in addition to which the legislature may establish inferior courts of law and equity. The supreme court sits at Montgomery. The judges of the several courts are elected by the people for a term of six years, and may be removed by impeachment or for reasonable cause by the governor on the address of two thirds of the legislature. Judges of the supreme, circuit, and chancery courts cannot hold any other office

of profit or trust under the state or United States during their judicial term. The salary of the governor is \$4,000, and of the judges of the three higher courts \$3,000 each. The right of suffrage is given to all male citizens and those who have declared their intention to become citizens, who have attained the age of 21 years and resided in the state six months next preceding the election, and three months in the county where their votes are offered. Those who during the late war violated the rules of civilized warfare, those disqualified on account of participation in the rebellion, those convicted of crimes punishable by imprisonment in the penitentiary, and those who are idiots or insane, are by the constitution prohibited from voting. The general assembly must provide from time to time for the registration of electors. Every person before registering is required to take an oath to support the constitution and laws of the United States and of the state of Alabama, and to swear that he is not disqualified by law from registering; that he will never countenance or aid in the secession of the state; and that he accepts the civil and political equality of all men. All able-bodied citizens between the ages of 18 and 45 are liable to duty in the militia. The governor is commander-in-chief of the militia, with power to call it forth to execute the laws and preserve the peace, and is required to appoint with the consent of the senate one major general and three brigadier generals of militia. The common schools and other educational institutions of the state are under the management of a board of education, consisting of the superintendent of public instruction, elected by the people for two years, and two members from each of the congressional districts, chosen for four years. The board is required to establish throughout the state, in each township or school district, free schools for all children between the ages of 5 and 21 years. By the law of 1870 it is forbidden to unite in one school white and colored children, except by the unanimous consent of their parents and guardians. The fund appropriated annually by constitutional provision for the support of public schools consists of the proceeds of all lands granted by the United States for school purposes, special appropriations, escheated estates, money paid for exemption from military duty, one fifth of the aggregate annual revenue of the state, and a poll tax of \$1.50. The constitution requires a state census to be taken in 1875, and every ten years thereafter, and provides for the establishment of a bureau of industrial resources at Montgomery, under the management of a commissioner, whose duty it shall be to collect statistical information concerning the productive industries of the state, to disseminate among the people knowledge tending to promote their agricultural, mining, and manufacturing interests, and to make an annual report to the governor, to be laid before the general assembly. It also provides for the

exemption from sale on execution of personal property of any resident to the value of \$1,000, and a homestead not exceeding \$2,000 in value. The real and personal property of a woman, whether acquired before or after marriage, is not liable for the debts of her husband, and may be devised and bequeathed by her the same as if she were a *feme sole*. The crimes of treason, murder in the first degree, rape, carnal intercourse with a woman by false representations of being her husband, and arson in the first degree, are punishable with death or imprisonment. Killing in a duel is murder in the second degree, and any one aiding in a duel is made incapable of holding any office under the state. Absolute divorce is granted for habitual drunkenness after marriage, physical incapacity, adultery, abandonment for two years, two years' imprisonment, or extreme cruelty. The legal rate of interest is 8 per cent. Alabama has 7 representatives and 2 senators in the federal congress.—The total taxation not national for 1870 amounted to \$2,982,932. The total receipts into the state treasury during the fiscal year were \$1,283,587, of which \$1,242,886 25 was from taxation and licenses. The total disbursements by the state treasury were \$1,366,399, of which \$23,843 was for the executive department, \$112,860 for legislative expenses, \$66,855 for judiciary, \$674,410 for educational purposes and schools, and \$251,564 for interest. The bonded debt of the state Sept. 30, 1871, was \$5,442,300, with interest amounting to \$321,106 annually; the total state debt was \$8,761,967 37.—Among the public institutions in the state are the penitentiary at Wetumpka, the insane hospital at Tuscaloosa, the asylum for deaf, dumb, and blind, and the freedman's hospital, at Talladega, and an asylum for the blind at Mobile. By the census of 1870 there were 611 blind, 401 deaf and dumb, 555 insane, and 721 idiotic; number of homicides during the year, 100. The number of convicts in the penitentiary in 1869 was 374.—The whole number of children attending school during the year 1870 was 77,139, of whom 31,098 were white males, 30,226 white females, 7,502 colored males, and 8,313 colored females. The number of persons 10 years old and upward unable to read was 349,771; unable to write, 383,012. Of those 21 years old and over who could not write, 17,429 were white males, 31,001 white females, 91,017 colored males, and 98,344 colored females. According to the state auditor's report, the number of public schools in 1869 was 3,225, and of normal schools 16. The total number of children of school age was 387,057, of whom 229,139 were white, and 157,918 colored. The state appropriates about \$500,000 annually (1871, \$590,605 50) for the support of common schools. By the census of 1860 there were 17 colleges, with 116 teachers and a total endowment of \$124,894; 206 academies and private schools, with 400 teachers and 10,778 pupils; and 395 public libraries, with 155,275 volumes. The university of Alabama, founded in 1831,

is situated at Tuscaloosa, and is under the control of the state board of education. During the civil war this institution was converted into a military academy. The principal building having been burned in 1865, the legislature in the following year loaned \$70,000 to the university for the erection of a new building, which has since been completed. The university owns some valuable lands and has an endowment of \$306,000, with an annual interest of \$24,000. Since the war it has not been in a prosperous condition. In January, 1871, there were 4 professors and 21 students.—In 1871 there were 71 newspapers and periodicals published in the state, of which 58 were weekly, 2 tri-weekly, 10 daily (which also issued weekly editions), and one semi-monthly. Their aggregate annual circulation was 8,891,432, and their average circulation 1,070.—The leading religious denominations are Methodists and Baptists. The former in 1860 had 777 churches, with accommodations for 212,555 persons, and church property valued at \$606,720; the latter 810 churches, worth \$495,449, with accommodations for 245,255 persons. There were 202 Presbyterian churches, valued at \$368,500, with accommodations for 65,004; 34 Episcopal, valued at \$196,050, with seats for 13,840; and 9 Roman Catholic, with 8,000 seats and church property worth \$230,450. There are other denominations in the state of less importance as to numbers.—The territory now forming the state of Alabama was originally a part of Georgia. In 1798 the country now included in the states of Alabama and Mississippi was organized as a territory, called Mississippi. At this time Florida, which then belonged to Spain, extended to the French possessions in Louisiana, from lat. 31° to the gulf of Mexico, cutting off Mississippi territory from the gulf coast entirely. During the war with Great Britain in 1812, as a precautionary measure, that part of Florida between the Perdido and Pearl rivers was occupied by United States troops, and finally annexed to Mississippi territory. After the removal of most of the Creek Indians from this territory as the result of a vigorous war in 1813-'14 (see CREEKS), the country was rapidly settled by the whites, and in 1817 the western portion was admitted into the Union as the state of Mississippi, while the eastern part remained as the territory of Alabama till 1819, when it was also admitted as a state. The slave population increased much more rapidly than the free, the proportion of slave to the free population being, according to the state census of 1855, as 239 to 289. The popular vote cast by Alabama at the presidential election of 1860, which resulted in the choice of Abraham Lincoln, was: for Douglas, 13,651; Breckinridge, 48,831; and Bell, 27,875. The state had instructed her delegates to the national convention held at Charleston in April of the same year to withdraw from that body unless the convention should adopt, among others, a resolution

affirming "the unqualified right of the people of the slaveholding states to the protection of their property in the states, in the territories, and in the wilderness in which territorial governments are yet unorganized." The convention having refused to declare in favor of this doctrine, the Alabama delegation withdrew. Early in December commissioners were sent by Alabama to the other southern states to urge the withdrawal of these states from the federal government, and their union in a separate confederacy; and on Dec. 24 an election was held for the choice of delegates to a state convention. These delegates were classified as immediate secessionists and coöperationists, the latter being in favor of secession with the coöperation of the other southern states. The convention assembled at Montgomery Jan. 7, 1861, and on the same day communications were received from the representatives of the state in congress, who had held a meeting in Washington, and passed resolutions advising immediate secession. On Jan. 11 the ordinance of secession was adopted by a vote of 61 to 39. The immediate cause of this action was stated in the preamble to the ordinance to be "the election of Abraham Lincoln and Hannibal Hamlin to the offices of president and vice president of the United States of America by a sectional party, avowedly hostile to the domestic institutions and to the peace and security of the people of the state of Alabama, preceded by many and dangerous infractions of the constitution of the United States by many of the states and people of the northern section." The convention held secret sessions and refused to submit its action to the people. These proceedings were followed by the withdrawal on Jan. 21 of the senators and representatives of Alabama from the federal congress, and the election of delegates to the southern congress, which assembled at Montgomery Feb. 4, to organize the southern confederacy. Forts Morgan and Gaines at the entrance to Mobile harbor and Mt. Vernon arsenal were seized by order of the governor, and on the 9th five companies of volunteers were sent to Pensacola, at the request of the governor of Florida, to assist in capturing the forts and other property there belonging to the United States. Subsequently a commissioner was sent to Washington to negotiate with the president for the transfer to the state authorities of the forts, arsenals, custom houses, and other United States property in the state. The president declined to receive this commissioner except as a "distinguished citizen of Alabama." On March 13 the state convention, which had reassembled on the 4th, ratified by a vote of 87 to 6, without submission to the people, the constitution adopted by the confederate congress, and subsequently passed an ordinance transferring to the provisional government the arms and munitions of war acquired from the United States, and also all authority over the forts and arsenals in the state. Laws were enacted by

the legislature placing the state upon an efficient war footing and appropriating \$500,000 to aid the cause of southern independence. On April 10 the president of the Confederate States made a requisition on the governor for 3,000 troops, and on May 1 the first battalion of the third state regiment left for Virginia. No important military operations occurred within the borders of Alabama during the first years of the war. In February, 1862, immediately after the capture of Fort Henry, Commander Phelps, with three gunboats from the fleet of Commodore Foote, proceeded up the Tennessee river and took possession of Florence at the foot of the Muscle Shoals. This was the first appearance of the national flag in northern Alabama since the beginning of the war, and was received with demonstrations of loyalty by many of the inhabitants who had opposed secession. On April 9 Gen. O. M. Mitchell, who had advanced from Nashville with a division of Gen. Buell's army, took Huntsville by surprise and gained possession of 100 miles of the Memphis and Charleston railroad between Stephenson and Decatur. He advanced westward to Tusculumbia, and thence as far south as Russellville, capturing confederate property without loss of life. The federal forces were soon compelled to abandon the territory south of the Tennessee river, but, having burned the railroad bridges at Decatur and Bridgeport, held all of Alabama north of that river. In the spring of 1864 a naval expedition was fitted out at New Orleans under Rear Admiral Farragut to operate against the fortifications guarding Mobile bay. He defeated the confederate fleet under Admiral Franklin Buchanan, Aug. 6, and, with the coöperation of a land force under Gen. Granger, reduced the forts at the entrance to the harbor—Fort Gaines on the 7th, and Fort Morgan on the 23d. Early in 1865 a combined military and naval expedition against Mobile was organized at New Orleans under Maj. Gen. Canby and Rear Admiral Thatcher; and a force of cavalry under Maj. Gen. J. H. Wilson was ordered to coöperate by a southern march from Eastport, Tenn. Wilson's command, numbering about 15,000, of whom 13,000 were mounted, advanced from Chickasaw March 23, and on April 3 occupied Selma, one of the most important military depots in the southwest. The arsenals, founderies, arms, tools, and military munitions of every kind, together with a large amount of cotton, were destroyed. From Selma Gen. Wilson moved eastward to Georgia, taking possession of Montgomery, the capital, on the 12th of April. On the same day Mobile was taken by Canby and Thatcher. During these operations "the last cannon," says Pollard, "was fired for the Confederacy." On May 4, at Citronelle, Ala., the forces, munitions of war, &c., in the departments of Alabama, Mississippi, and East Louisiana were formally surrendered by Gen. Taylor to Gen. Canby; and on the same day Commodore Farrand surren-

dered to Rear Admiral Thatcher all the confederate naval forces—12 vessels—then blockaded on the Tombigbee. No official statement of the number and losses of Alabama troops in the war has been made. In an official proclamation, in June, 1865, Provisional Governor Parsons stated the number of troops furnished by the state during the war to be 122,000, and the losses 35,000. Montgomery was the seat of the confederate government until its removal to Richmond on the 20th of May, 1861. Immediately upon the close of the war measures were instituted by the general government for the restoration of Alabama to the Union. For this purpose Lewis E. Parsons was appointed provisional governor June 21, 1865, with instructions to call a convention for the purpose of altering and amending the constitution and laws of the state in conformity with the federal constitution. At the election held Aug. 31 for choice of delegates, those citizens were qualified as electors and delegates who were entitled to vote by the constitution and laws of Alabama in force immediately prior to Jan. 11, 1861, and who had taken the oath of amnesty as set forth in the president's proclamation of May 29, 1865. After assembling on Sept. 10, the convention reordained the civil and criminal laws, except those relating to slaves, as they existed previous to the adoption of the secession ordinance of 1861, declared that ordinance and the state war debt null and void, passed an ordinance against slavery, and provided for an election of state officers and members of congress to be held in November. On the assembling of the legislature, United States senators were chosen, and on Dec. 19 the newly elected governor assumed executive control. The government thus organized continued in force until supplanted by the military government provided by congress in pursuance of the reconstruction act passed March 2, 1867. By this act Alabama was made subject to the military authority of the United States, and, with Georgia and Florida, constituted the third military district. On April 1, 1867, Major General Pope assumed command of this district with a sufficient military force to protect the rights of all persons, and to preserve the public peace. In accordance with the supplemental act of congress of March 23, 1867, a registration of qualified voters (excluding unpardoned participants in the civil war) was made in August, when 165,813 persons were registered, of whom 61,295 were white and 104,518 colored. An election was held on the first three days of October to decide the question of calling a convention for the purpose of forming a constitution and civil government, and also to choose delegates to the convention; 90,283 votes were cast for the convention and 5,583 against it. The convention assembled in November and framed a constitution, which was submitted to the people in February, 1868, when 70,812 votes were cast for ratification and 1,005 for rejection. The total vote thus

cast, being less than the majority of all the registered voters required by the reconstruction law of congress, was not sufficient for ratification. The constitution was, however, by a subsequent act of congress, declared adopted. At the same election state officers and members of congress and of the legislature were chosen. The legislature having assembled and complied with the requirements of the law of congress for the admission into the Union of certain southern states passed June 25, 1868, Alabama became entitled to representation in congress, and on July 14, 1868, the control of affairs passed from the military to the civil authorities. The 15th amendment to the federal constitution was ratified by Alabama Nov. 16, 1870, the 14th amendment having been previously ratified as a condition of representation in congress.

ALABAMA, a river of the state of Alabama, formed by the union of the Coosa and Tallapoosa rivers about 10 m. (direct) N. N. E. of Montgomery. It has a westerly course as far as Selma, whence it flows southerly until it joins the Tombigbee about 50 m. above Mobile, to form the Mobile river. It is navigable for vessels of 6 feet draught to Claiborne, 60 m. above the junction. Small steamboats ascend it to Montgomery, 320 m. by the course of the river, the depth of water being from 3 to 5 feet, and in high water about 20 m. further to Wetumpka on the Coosa. The river is very tortuous throughout its course, and on its banks are some of the largest cotton plantations in the South, and much valuable timber. The most important cities and towns on the Alabama are Montgomery, Selma, Cahawba, and Claiborne.

ALABASTER, the name frequently given to two different mineral substances—the one a sulphate of lime, a pure variety of gypsum, and the other a carbonate of lime, of the same chemical composition as most of the marbles. It was used with the same ambiguity by the ancient Greeks and Romans. The resemblance of the two substances is in their delicate white color and fine grain. Each is easily carved and susceptible of a fine polish. They might well in ancient times have passed as varieties of the same substance: the gypsum alabaster being more delicate and softer to cut, and requiring much more care to polish; the calcareous alabaster more firm, and better adapted for the sculpture of larger figures. The latter was frequently obtained from the drippings of the water in limestone caves, which holds carbonate of lime in solution, and deposits it in the form of stalactites and stalagmites. These by a little ingenuity were made to take the forms of the mould the waters dripped upon; or the natural stalagmites of the purest colors were selected, and then wrought into the desired figures.—The name alabaster, now properly limited to the gypseous variety, is derived from the town Alabastron, the site of which is believed to have been between the Red sea and the Nile in Middle Egypt. Here the stone was

extensively wrought into boxes and pots for precious ointments and perfumes. A white granular gypsum, pure and in sound blocks, is quarried in Siena and in other places in Tuscany, and manufactured in Florence, Leghorn, Milan, and Volterra, into utensils similar to those used of old, as well as into vases, lamps, clock stands, &c. They are exported from these places in considerable quantity to the United States. The composition of this alabaster is 46.3 per cent. sulphuric acid, 32.9 lime, and 20.8 water. Its hardness is 1.5-2 of the mineralogical scale. It soon tarnishes on exposure to the air, and is easily injured by dust and smoke. Articles made of it should be kept under a glass cover.

ALACHUA, a county of Florida, in the N. part of the peninsula, bounded N. by the Santa Fé river and W. by the Suwanee; area, 1,000 sq. m.; pop. in 1870, 17,328, of whom 12,393 were colored. Orange lake lies partly within its limits. The surface is rolling prairie and the soil is fertile. The productions in 1870 were 168,580 bushels of corn, 8,450 of oats, 18,264 of potatoes, 2,477 bales of cotton, 58 hhds. of sugar, and 22,906 gallons of molasses. The Florida railroad passes through the county. Capital, Gainesville.

ALACOQUE, Marguerite Marie, a French nun, to whom the festival of the Sacred Heart of Jesus owes its origin, born at Lauthecour, diocese of Autun, July 12, 1647, died Oct. 17, 1690. She took the veil in the Visitation convent of Paray-le-Monial, where, according to her biographers, she displayed the gifts of miracles, of prophecy, of revelations, and direct intercourse with God and his angels. She predicted the day of her own death, and experienced ineffable pleasure while engraving the name of Jesus Christ on her bosom with a penknife. She left a treatise on *La dévotion au cœur de Jésus*, which she believed to embody a supernatural communication. The church gives her the title of venerable.

ALA DAGH. **I.** A lofty mountain chain in Asiatic Turkey, on the northerly side of which the eastern Euphrates takes its rise. Its main portion is situated on the N. edge of the basin of Lake Van, between lat. 39° and 40° N., and lon. 42° and 44° E., and forms part of the watershed between the Caspian sea and the Persian gulf. **H.** A range in Asia Minor, to the N. W. of Angora, extending between the Ishik Dagh on the N. E. and the valley of the Sakaria on the S. and W.

ALAGOAS, Dos, a province of Brazil, on the Atlantic coast, bounded N. and W. by Pernambuco, and separated from Sergipe on the S. by the San Francisco river; area about 11,000 sq. m.; pop. about 300,000, of whom 50,000 are slaves. A considerable portion of its surface is covered with mountains, at the base of which the land is very fertile. The mountains afford large quantities of timber for export, and in the valleys cotton and sugar are cultivated. Tropical fruits of all kinds are grown in abundance, and dragon's blood, mastic, ipecacuanha, copaiba,

caoutchouc, &c., are obtained in the woods. The climate is warm and humid, and in the rainy season oppressive. The population is very unequally distributed, the lowlands being most densely peopled. Some of the native tribes still live in the mountains, and subsist by the chase. The principal occupation of the people is agriculture. Porto Calvo is the capital; Macayo or Maceio the chief seaport.—**Alagoas**, the former capital, is situated on a lake opening into the ocean, 150 S. S. W. of Pernambuco; pop. about 12,000. There are several convents and grammar schools.

ALAIN DE LILLE (Lat. *Alanus de Insulis*), a Cistercian scholar, born in 1114, died about 1203. He was called the Universal Doctor, and was one of the most profound savants of the 12th century. He was a philosopher, physician, theologian, poet, and historian, and was appointed to the bishopric either of Auxerre or of Canterbury, which he soon resigned in order to enter the monastery of Cîteaux. Five countries dispute the honor of his birth, Germany, Scotland, Spain, Sicily, and Flanders. He himself says he came from Lille in Flanders. He wrote, principally in verse, on alchemy, natural philosophy, doctrinal and moral theology, &c.

ALAIS, a city of S. France, department of Gard, on the Gardon, 25 m. N. N. W. of Nîmes; pop. in 1866, 19,964. There are numerous iron furnaces, silk mills, and glass works; and coal is mined in the vicinity to the extent of 1,000,000 tons annually. It is a great depot of the raw silk of S. France.

ALAJUELA, a city of Costa Rica, Central America, 14 m. N. W. of San José, the capital; pop., including suburbs, about 10,000. It is a place of considerable commercial importance, and is connected with the port of Puntas Arenas, on the gulf of Nicoya, by an excellent mule road.

ALAMAN, Lucas, a Mexican statesman, born in the latter part of the 18th century, died June 2, 1855. He was a member of the cabinet under Bustamente in 1829, and in 1853 Santa Anna appointed him minister for foreign affairs. He induced Santa Anna to decree the abolition of the liberty of the press, with severe punishments for the infraction of the new law on this subject, the restoration of the confiscated property of the Jesuits, a regular recruiting system, and a reorganization in the army. By his influence onerous taxes were imposed upon the impoverished population, and a law was passed for cashiering all Mexican officers who had voluntarily surrendered to the American government. He was the author of *Historia de Méjico* (5 vols., Mexico, 1849-52).

ALAMANCE, a N. county of North Carolina; area, 500 sq. m.; pop. in 1870, 11,874, of whom 3,640 were colored. The river Haw, a branch of the Cape Fear, runs through the centre of the county, and through the W. part Alamance creek flows into the Haw. The soil is fertile and the surface undulating. The productions

in 1870 were 86,284 bushels of wheat, 177,772 of corn, 66,274 of oats, and 155,570 lbs. of tobacco. In 1867 there were 26 churches, 4 academies, 5 cotton factories, and 5 flour mills. The North Carolina railroad traverses the county E. and W. Capital, Graham.

ALAMANNI, or *Alemanni*, **Luigi**, an Italian poet, born at Florence in 1495, died at Amboise, France, in 1536. His father was devoted to the party of the Medici. Suspected of conspiring against the life of Cardinal Julius, who was governing Florence in the name of the pope, he fled first to Venice, and, after the accession of the cardinal to the papal throne under the name of Clement VII., to France. Repeated attempts to reestablish himself in his native city failed. Francis I., who had a high opinion of him, finally took him into his service, and, after the peace of Crespy in 1544, appointed him ambassador at the court of Charles V. He retained the good will of the successor of Francis, Henry II. He left many poems, satires, fables, and other light literature. His principal work is his didactic poem, *La Coltrivazione* (Paris, 1546).

ALAMEDA, a W. county of California, on San Francisco bay; area, 820 sq. m.; pop. in 1870, 24,237, of whom 1,939 were Chinese. The San Francisco and Alameda, and the San José and Stockton railroads run through the county. Gold and some other minerals are found in small quantities. The principal productions in 1870 were 854,888 bushels of wheat, 668,975 of barley, 69,080 of oats, 114,053 of potatoes, 138,975 lbs. of wool, 198,910 of butter, and 23,464 tons of hay. There were 6 newspapers published, of which 3 were dailies. The scenery of this county is very attractive. The warm springs, in a little valley among the foot hills of the Coast range, are much frequented for their medicinal properties, the water containing sulphur, lime, magnesia, and iron, in various proportions. Capital, San Leandro.

ALAMO, a fort in Bexar county, Texas, near San Antonio, on the left bank of the San Antonio river, celebrated in the Texan war for independence. It was an oblong structure, about an acre in extent, surrounded by a wall 8 or 10 feet high and 3 feet thick. Gen. Sam Houston had caused San Antonio to be dismantled, upon which Santa Anna with a large detachment of his army invested Fort Alamo, Feb. 23, 1836. The Texans, consisting only of 140 men, commanded by Col. William Barrett Travis, retired into the fort, while the Mexicans, 4,000 strong, after taking possession of the town, erected batteries on both sides of the river, and bombarded the fort without cessation for 24 hours. During this time over 200 shells were discharged into the fort, yet not a man was injured, while the Texan sharpshooters, standing upon the ramparts, were able to pick off man after man of the enemy. Several assaults were now made, but in every instance the Mexicans were repulsed with loss. Col. Travis repeatedly sent couriers to San

Felipe asking for assistance, but only 32 men succeeded in forcing their way through the Mexican army and reaching the garrison. By March 3 scarcity of provisions, combined with constant watching, had undermined the health of the men, without, however, affecting their spirits. Before daybreak on the 6th a combined attack was made by the whole Mexican force. Twice assaulting, they were twice driven back, with severe loss. The Texans, unable to load in the hand-to-hand fight which now ensued, clubbed their rifles and fought with desperation until but six of their band remained alive. These, including Col. Crockett, surrendered to Castrillon, under promise of protection; but being taken before Santa Anna, they were by his orders instantly cut to pieces. Col. Crockett fell stabbed by a dozen swords. Col. Bowie, ill in bed, was then shot, after having killed several of his assailants. Major Evans was shot while in the act of firing the powder magazine. The bodies of the slain were collected in the centre of the Alamo, and after being horribly mutilated (in which act, it is said, Santa Anna and his generals joined), they were burned. But three persons, a woman, a child, and a servant, were spared. The Mexican loss was 1,600. The massacre of the Alamo was followed by the battle of San Jacinto, the defeat of the whole Mexican army, and the capture of Santa Anna himself, with his best generals. At this battle the Texans, with the war cry of "Remember the Alamo!" carried all before them.

ALAMOS, *Real de los* (Camp of the Poplars), a town in the southern part of Sonora, Mexico, 175 m. S. W. of Chihuahua, and about 45 m. E. of the gulf of California; pop. about 11,000. The houses are built of stone or brick, overlaid with stucco, the streets are tolerably well paved, and the place is celebrated for the beauty of its avenues (*alamedas*). It was severely injured by a storm in November, 1868. The district of Alamos, extending to the gulf of California, is famous for its rich copper and silver mines, and for its salubrious climate, its average height being several hundred feet above the gulf. The silver mines in the vicinity of the town employ about 4,000 persons.

ALAN, *Allen*, or *Allyn*, **William**, an English theologian, born in Lancashire in 1532, died in Rome, Oct. 6, 1594. Being a zealous Catholic, he left England soon after the accession of Elizabeth, and settled in Flanders, where he published several works in defence of the old faith. In 1568 he founded the famous ecclesiastical college of Douay for the education of English youth, Pope Gregory XIII. assisting him with a subsidy. Ten years later the magistrates ordered it to be closed, and Alan removed the establishment to Rheims, but it was restored to Douay in 1593. Dr. Alan was concerned with other professors of this college in making the English translation of the Bible commonly known as the Douay version. He was deeply implicated in the Catholic schemes

for dethroning Elizabeth, and when the Spanish armada was fitted out, Philip II. caused the pope to give him a cardinal's hat, the design being that Alan should accompany the expedition as papal legate. Instead of embarking in person, Cardinal Alan supplied the fleet with copies of a pamphlet against Elizabeth, entitled an "Admonition to the Nobility and People of England." He was made archbishop of Mecllin in 1591, but at the desire of Pope Sixtus V. he continued to reside in Rome.

ALAND ISLANDS, a group of about 200 rocky islets, of which 80 are inhabited, situated at the entrance of the Bothnian gulf, between lat. 59° 55' and 60° 32' N., and lon. 19° and 21° E. They belong to Russia, having been ceded by Sweden in 1809, and form a part of the government of Abo-Björneborg in Finland. The inhabitants, about 16,000, are Swedes, and are excellent sailors and fishermen. They keep great numbers of cattle, and export cheese, butter, and hides; they also manufacture cloth for home use and for sails. The group takes its name from the largest island; area, 28 sq. m.; pop. 10,000. It has a good harbor on the W. side. Foremost among the former fortifications was the fort of Bomarsund, near the S. E. extremity of the main island, which was captured in 1854 by the allied fleets of England and France during their war against Russia, and blown up on their departure. By the treaty of Paris of 1856 Russia is prohibited from fortifying the islands or having there any military or naval station.

ALANI, a tribe of Scythians, frequently appearing in connection with the various German invaders of the Roman world during the great migration of the nations of the north. Their origin is uncertain, though they seem to have been of Finnish stock. They originally dwelt about the eastern part of the Caucasian mountains, whence they extended toward the Don, and also made inroads into Armenia and Asia Minor. Vologeses, king of the Parthians, invoked against them the aid of the emperor Vespasian. Arrian the historian, lieutenant of the emperor Hadrian in Cappadocia, successfully warred against them. They are mentioned as excellent horsemen and marksmen with the bow. In the time of Aurelian they united with the Goths and invaded Asia Minor, but were expelled about 280 by the emperor Probus. In the later years of the 4th century they were routed by the Huns, and, joining their conquerors, drove out the Goths from the region between the Don and the Danube, and shared in the great movement of the northern tribes toward the southwest of Europe. Conjointly with the Sævi and the Vandals, in 406, they invaded and devastated Gaul. A body of the Alani who remained south of the Loire appeared in 451 as allies of Aëtius against Attila. Another body of them marched in 409 into Spain, but were there overpowered by the Visigoths, and driven into Lusitania, where their name disappeared. Still other Alani invaded

northern Italy half a century later, and were almost totally destroyed. The annals of the Byzantine empire also mention the Alani as devastating both the regions on the Danube and in the Caucasus.

AL-ARAF, in Mohammedan theology, the wall of separation between heaven and hell, corresponding somewhat to the purgatory of the Latin church. Sitting astride of this wall are those whose good and evil deeds so exactly balance each other that they deserve neither heaven nor hell, and those who have gone to war without their parents' consent and fallen in battle. These last are martyrs, and are therefore preserved from hell, but, inasmuch as they have disobeyed their parents' commands, they are not deemed worthy of heaven.

ALARCON, Hernando de, a Spanish navigator of the 16th century, to whom we owe the first certain knowledge concerning the configuration of the peninsula of California. This had previously been held to be an island. Alarcon set sail in the service of the Spanish court May 9, 1540. On the W. coast of America he expected to make a junction with the expedition commanded by Coronado; but the two commanders missed each other. Alarcon left an inscription on a tree at the place where they should have met, which was discovered by a third Spanish navigator. The inscription was: "Alarcon came to this point; at the foot of the tree are buried letters." These letters conveyed the intelligence that Alarcon, after having tarried there for some time, had returned to New Spain; that the supposed sea was a gulf; that he had sailed round the Marquis island; and that California was not an island, but a point of land jutting into the Pacific. Alarcon returned to New Spain in 1541, and there drew up his maps and observations. His discoveries and those of Fernando de Ulloa were applied to such good use, that an eminent geographer has said the map of California made in 1541 differs hardly at all from that constructed in our own day.

ALARCON, or Alarcon y Mendoza, Juan Ruiz de, a Spanish dramatist, born in Mexico of a noble Spanish family, died in Spain in 1639. In 1628 he published the first volume of his dramas, on the title page of which he styles himself prolocutor (*velator*) of the royal council for the Indies. To the eight plays contained in this volume he added twelve more in 1635. His best known comedy is *La verdad sospechosa*, which served as a model for Corneille's *Menteur*. Another of his comedies, *Las paredes oyen*, is still popular on the Spanish stage. A new edition of his plays has been published by Hartzenbusch (Madrid, 1848-52).

ALARIC I. King of the Visigoths, born about 376, died in 410. Previous to his reign the Goths north of the Danube (mostly Arians), being pressed by the Huns, claimed the protection of the Roman emperors, who allowed them to cross the Danube and establish themselves on its southern side in Mœsia (modern Bulgaria) as

paid allies of the empire. On the death of Theodosius (395), who divided the empire between his two sons, Alaric, profiting by the weakness resulting from the division, invaded Thrace, Macedonia, Thessaly, and central Greece, without meeting resistance on the part of Rufinus, the lieutenant of the emperor Arcadius. Athens was obliged to pay a ransom. Alaric entered the Peloponnesus, where he was encountered in Elis by a powerful army under Stilicho, the lieutenant of Honorius, emperor of the West. Stilicho tried to surround the Goths on the banks of the Pencus, but Alaric broke through his army, escaped with his plunder and prisoners to Illyricum, concluded peace with Arcadius, and was made by him the commander of the eastern division of that country in 396. From Illyricum, in 402, Alaric invaded Italy. Honorius shut himself up in Ravenna, while Alaric, marching through northern Italy toward Gaul, was met and defeated by Stilicho near Pollentia on the Tanaro (403) and obliged to retreat. He sustained a second defeat in the same year near Verona, after which he returned to Illyricum, and concluded a treaty with Honorius, undertaking to invade the eastern empire and join his army with that of Stilicho in Epirus. This project being afterward abandoned by Honorius, Alaric claimed a compensation for the cost of his armaments and march, and was promised 4,000 pounds of gold. Stilicho, who made the promise in the name of the emperor, being beheaded in 408, and the promise broken, Alaric invaded Italy, invested Rome, and received as ransom from the city 5,000 pounds of gold and 30,000 pounds of silver. Further negotiations for peace having proved unsuccessful, Alaric for the second time laid siege to Rome. Hunger obliged the city to conclude an arrangement, and in compliance with the will of the conqueror the senate elected as emperor the Roman general Attalus. Shortly afterward, being dissatisfied with the incapacity of his nominee, Alaric ordered him to resign. Renewed negotiations with Honorius were unsuccessful, pending which Alaric's army was treacherously attacked near Ravenna, and he undertook the siege of Rome for the third time. On August 24, 410, he took the city by assault, and it was plundered by the Goths for three days. After remaining there six days, Alaric marched out, intending to make the conquest of Sicily, but died soon after in Cosenza. The Goths, it is related, turned from its bed the stream of the Busento, to bury their chief there, with all his treasures; and all the prisoners who performed the work of digging were killed, that the Romans might never be able to find the place where the remains of the king were deposited. II. King of the Visigoths, succeeded his father Euric in 484, died in 507. His dominions extended S. from the Loire and Rhône over Hispania Tarraconensis and Bætica, thus covering the S. W. third of the present territory of France and nearly the whole of Spain. He

was peaceful and tolerant, and, though an Arian in religion, granted many privileges to the orthodox Catholics. Clovis, king of the Franks, made religion a pretext for invading Gothia, and defeated Alaric at Vouglé, near Poitiers. Alaric fled, but was overtaken and killed. Theodoric, king of Italy, the father-in-law of the slain monarch, became regent during the minority of Alaric's son Amalaric, compelled the Franks to give up their conquests, and put down a rebellion of the supporters of Alaric's bastard son Gesalic.

ALARM, an instrument to give notice by sound. In its most ordinary form it consists of a bell and a hammer, combined with an escapement that lets it free at the proper time, when a descending weight or a spring makes it strike the bell.—Burglar alarms are of various forms. Some consist in an arrangement for firing a pistol, and are connected either with the lock or with the door. Some of them are so arranged as to shoot the thief at the same time that they wake up the inmates. An alarm for this purpose may always be put up at a moment's notice, by stretching a string across the hall, one end attached to the knob of a door and the other to the trigger of a pistol, or to some glass or brass vessel placed on the edge of a table or at the top of a flight of stairs, which will tumble down with a noise the moment the string is pulled by any one opening the door or crossing the hall. An alarm is easily made by arranging the wires in the circuit of a galvanic battery in such manner that the circuit may be broken when a door or window is opened; the falling of an electro-magnet which was supported by the electrical current then gives the motive power for ringing a bell or other sound-producing instrument.—An alarm clock is a clock for sleeping rooms, provided with an alarm that may be wound up to strike at any appointed time, and so awake the sleeper. It consists of an ordinary clock with an alarm attached, which requires to be wound up at a separate keyhole from that which winds the clock, and after each alarm requires rewinding to give it impulse for another. The alarm is commonly set, to go off at the required hour, by means of a disk which lies under the hour hand of the clock, revolving upon the same axis and with that hand. The disk has the 12 hours printed in the same order and position as on the clock face, and when this disk is brought into the same position as the clock face, that is, having the 12 on the disk at its highest point, the clock then by mechanism sets off the alarm. In order to cause the alarm to sound at 4 o'clock, for instance, the number 4 on the disk is brought under the hour hand, which latter carries the disk forward till 4 o'clock, and at this moment the 12 on the disk will be at its highest point and the alarm is set off.—The fire-damp alarm is an important invention, due to M. Chaptal from France, and liberally given by him to the public. It consists of a small ball of glass or

of brass suspended at the end of a lever, and containing a chemical solution highly sensitive to the gas constituting fire damp. Long before the atmosphere has become sufficiently vitiated to be dangerous to life, or to be capable of exploding, the chemical action in the ball has altered its weight, and thus caused the lever to move and let go an escapement which sounds an alarm.—An alarm whistle is a steam whistle set on a boiler to give notice when the water falls below its proper level. For this purpose the whistle-cock is connected by a lever with a float, and opens when this float goes below a certain level. The steam rushing through the whistle sounds the alarm.

ALASCO, John. See LASKI.

ALA-SHEHR, a city of Turkey, in Asia Minor, in the eyalet of Aidin, at the N. E. base of the Boz Dagh (the ancient Mt. Tmolus), 75 m. E. by S. of Smyrna; pop. about 13,000, of whom 3,000 are Greeks. It is built on the site of ancient Philadelphia, is surrounded by a wall, and contains many ruins, including a large number of Christian churches. It is situated on the caravan route from Smyrna to the interior, and has a thriving trade.

ALASKA, a territory belonging to the United States, formerly known as Russian America. It comprises all that portion of the North American continent lying W. of the 141st parallel of W. longitude, together with a narrow strip of land between the Pacific ocean and the British dominions, separated from the latter by a line drawn as follows: beginning at the southernmost point of Prince of Wales island, in lat.

54° 40' N., running thence N. along Portland channel to the point of the mainland where it strikes lat. 56° N., and from this point along the summits of the mountain range parallel to the coast, except where the distance of such summits from the ocean exceeds 10 marine leagues, to its intersection with the 141st meridian. Wherever the peaks are situated further inland than the distance specified, the line is drawn, parallel to the winding of the coast, at that distance from it. The territory also includes all the islands near the coast, and the whole of the Aleutian archipelago except Behring island and Copper island on the coast of Kamtchatka. In the dialect of the natives first encountered by the Russian explorers, the peninsula now known as Alaska was called Al-ay-es-ka, the name having become changed through Alaksa and Alashka to its present form, from which last is derived the general territorial designation Alaska, which Dall asserts to be an English corruption never used by the Russians. The area of Alaska, including the islands, is 580,107 sq. m.; pop. in 1870, 29,097, of whom 26,843 were natives of the territory, 1,421 were half-breeds, 483 were Russians, and 350 were natives of the United States and foreigners not Russians. There are not more than 1,300 completely civilized inhabitants.—Sitka, or New Archangel, the capital of the territory and its only considerable town, is situated on a small but commodious harbor on Baranov island, in lat. 57° 3' N., lon. 135° 17' W. It was long the headquarters of the Russian-American fur company,

though the natural centre of the fur trade is the island of Kadiak, S. of the Aliaska peninsula. At the time of the transfer of the territory to the United States in 1867, Sitka, although founded in the last century, was little better than a collection of log huts, about 100 in number, with a few superior buildings occupied by government officers. St. Paul, the principal settlement on Kadiak island, is the main depot of the seal fisheries, and is surrounded by the finest farming land in the territory. Next in importance as a settlement is Captain's Harbor, on the island of Unalaska, where is found the best anchorage in the Aleutian group. The remaining civilized places in Alaska consist for the most part of small trading posts scattered throughout the country, the principal of them being Fort Yukon, approximately in lat. 66° N., the most northerly station of the Hudson Bay company, which for some years paid the Russian-American fur company a royalty for the privilege of thus trading in their territory. Michaelovski, a station of the Russian company on Norton sound, in lat. $63^{\circ} 28'$ N., and lon. $161^{\circ} 44'$ W., is of considerable importance as affording the best harbor on the coast from which to forward goods into the Yukon valley.—The interior of Alaska has been but slightly explored, and our knowledge of the country is confined mainly to the islands, the coasts, and a few of the larger rivers. The entire coast line of the territory, without taking into account the smaller indentations, measures about 4,000 m. in length, and is bordered by three seas: the Arctic ocean on the N., Behring sea on the W., and the North Pacific on the S. The coast formation along the North Pacific differs entirely from that N. of the Aliaska peninsula. Point Barrow, a long arm of low sandy land projecting into the Arctic ocean, forms the most northerly cape in the territory. Between this point and Behring strait, the only considerable indentation of the coast is Kotzebue sound, with a maximum depth of 14 fathoms, and the shore is low and swampy except at Cape Lisburne, where the limestone rock rises to the height of 850 feet above the sea. Cape Prince of Wales, the E. boundary of Behring strait, is the most western land on the American continent, being situated in lat. $65^{\circ} 33'$ N., lon. $167^{\circ} 59'$ W., only 54 m. from East cape, the nearest part of Asia. It is a rocky and precipitous promontory. The nearest harbor is Port Clarence, a short distance S., where there is a safe anchorage in 10 fathoms of water, with a bottom of soft mud. Below this inlet the country becomes low and rolling, and is not very accessible from the ocean, even in the larger bays, on account of the shoals formed of alluvium brought down by the rivers, which is retained in Behring sea by the rocky barrier of the Aliaska peninsula. Norton sound is so shallow that vessels have been known to run aground there at the distance of a mile from the shore; but it affords a few harbors, as also does Bristol bay, which

opens into the region N. of the same rugged and barren peninsula from which the name of the territory is derived. Stretching westward toward Kamtehatka lie the Aleutian islands, so called from the name Aleuts applied to their inhabitants by the Russians. Unimak is the largest of these, and Unalaska of the greatest commercial importance. The celebrated fur seal group, named after Pribyloff, its discoverer, is situated in Behring sea, lat. 57° N., lon. $169^{\circ} 30'$ W., and consists of four small islands called respectively Walrus, Beaver, St. George, and St. Paul. Below Aliaska the coast becomes mountainous, with deep soundings close in shore. Between lon. 151° and 158° W. lies the Kadiak archipelago, including the large island of that name. Cook's inlet and Prince William sound, or Chugach gulf, are the principal arms of the sea on the North Pacific coast of the territory, until we reach the narrow strip of mainland S. of Mt. St. Elias, which is protected from the sea by the 1,100 islands of the Alexander archipelago, situated between Cross sound and Dixon's entrance. The almost innumerable channels between the islands of this vast series afford the finest inland navigation. Prince of Wales island is the largest member of the group, which also contains Baranov island, the site of Sitka.—The great river of Alaska is the Yukon, or Kwiekpak, as it has erroneously been called by the Russians, from the name of one of its mouths. It rises in British Columbia, enters Alaska near the Arctic circle, and flows, with a general S. W. trend, across the entire width of the territory into Behring sea. Its length is more than 1,800 m., and it is over a mile broad at a point 600 m. above its delta. Its current varies in rapidity from 3 to 7 m. per hour, and in summer the river is navigable for light-draught steamers throughout three fourths of its length. Next to the Yukon in size is the Kuskokwim, which also flows into Behring sea, somewhat further S. It has been explored by the Russians some 600 m. above its mouth, and is a very crooked and moderately rapid stream, navigable for a considerable distance. The principal rivers of Alaska which flow into the North Pacific ocean are: the Copper river, which reaches the coast in lat. 60° N., lon. 145° W., and about which very little is known; the Chilkait, a rapid stream, which enters Lynn channel W. of Cross sound, and the head waters of which approach so close to a tributary of the Yukon that a short portage affords the Indians easy communication between the two rivers; and, still further S., the Stikine or Francis river, forming the gateway to the gold region of British Columbia. Lakes are said to be numerous in the interior of the country.—Alaska is emphatically a country of volcanoes, there being no fewer than 61 volcanic peaks already known in the territory, though but 10 of these are in activity at present. The peninsula of Aliaska, and the Aleutian islands, which really constitute a continuation of it, are of volcanic

origin, and the same is true of the islands along the coast of Behring sea. So far as known, all the mountains in the country of any considerable height are situated below lat. 65° N. There are three important mountain chains: the Coast or St. Elias range, the Rocky mountains, and the Alaskan range. In the Coast range, on the North Pacific, are the loftiest peaks and principal volcanoes. Of these Mt. St. Elias is the highest; its elevation is variously stated at from 16,000 to 17,850 feet, the latter estimate making it the highest mountain in North America. The summit of Mt. Fairweather, in the same chain, is 14,500 feet above the sea level. E. of the Yukon, the Rocky mountains extend along or near the 64th parallel to the basin of the Mackenzie river. The Alaskan range in the S. W. part of the territory is merely an offshoot of the Rocky mountains. There is a long line of low hills near the Arctic coast.—The climate of Alaska is by no means so inhospitable as that of corresponding latitudes on the eastern coast of North America. In regard both to climate and agriculture, the territory is naturally divisible into three regions: the Yukon district, comprising all the country N. of the Alaskan mountains; the Aleutian district, comprising the islands of that name and the peninsula; and the Sitka district, comprising the remainder of the territory. In the Yukon district the mean annual temperature is about 25° F., and the ground remains frozen to within two or three feet of the surface throughout the summer. The amount of rainfall is not accurately known. In winter the ice on the Yukon averages five feet in thickness, and where there is sufficient water it has been known to freeze to a depth of nine feet. The summer is short, dry, and hot. May, June, and a part of July constitute the pleasant season; then the rainy weather begins, and lasts till October. The lowest temperature ever recorded in this region was -70° F. The climate of the Aleutian district is warmer, the mean annual temperature being from 36° to 40° F. In a series of observations made at Unalaska, extending over five years, the greatest cold experienced during that time was found to be the zero of Fahrenheit, while the highest temperature was 77° . The average annual rainfall is about 40 inches, distributed among 150 rainy days in each year. January, February, and June are the pleasantest months. A still warmer and moister climate is characteristic of the Sitka district. The town of Sitka is the rainiest place in the world outside of the tropics. From 60 to 90 inches of rain fall annually, and the number of rainy days in each year varies from a minimum of 190 to a maximum of 285. The mean annual temperature is 44.07° ; but the average temperature in winter is proportionately much higher than in summer, being only a little below the freezing point; while the excessive rains in summer make that season unduly cold. Ice fit for consumption scarcely ever forms at Sitka.—The

interior of Alaska is well wooded. On the Pacific coast, dense forests of the Sitka spruce or white pine (*abies Sitkensis*) clothe the mountain sides both of the islands and the mainland, down to the very water's edge, producing timber of great size and unsurpassed quality. In the same region grows the yellow cedar (*C. Nutkatensis*), of great value for boat-building. Hemlock and the balsam fir are also found here. The Aleutian islands are wholly destitute of trees, there being no vegetation on them larger than a shrub. In the Yukon region, the wooded district recedes from the coast, but timber is abundant in the interior, the finest tree which occurs there being the valuable white spruce (*abies alba*). The birch (*betula glandulosa*) is also found, and furnishes the only hard wood in this part of the country. Alders, poplars, and several varieties of willow fringe the banks of all the larger streams.—The agricultural resources of Alaska are practically confined to the Aleutian and Sitka districts. The abundant growth of rich perennial grasses in the valley of the Yukon affords excellent fodder for cattle, but no grain has ever been raised there, and the only vegetables which have succeeded are radishes, turnips, and lettuce. The most fertile land is found at Cook's inlet, on Kadiak island, and among the Aleutians, where good oats, barley, and root crops can be raised without much difficulty. Whether the potato can ever be cultivated successfully in Alaska is doubtful. In the most favored farming districts the agricultural production can scarcely ever exceed the local demand.—Alaskan geology has been but imperfectly studied, and only a few of the leading facts are known. According to William H. Dall, the director of the scientific corps which explored the proposed route for the Russo-American telegraph line in 1866, the whole of the peninsular portion of Alaska W. of lon. 150° is gradually rising. Along the Pacific coast glaciers, some of them remarkable for their extent and grandeur, fill the principal mountain gorges, and terminate at the sea in magnificent masses of overhanging ice. The fact that these glaciers are gradually decreasing in size from year to year leads to the inference that the rigor of the climate is slowly mitigating. Hot and mineral springs are found near Sitka, on the Aleutian islands and the neighboring coast, and in other parts of the territory. In the Alexander archipelago fossils of the cretaceous period have been found, but the extent of the formation has not been ascertained. Clay slates and conglomerate occur near Sitka. Crystalline white marble of fine quality has been discovered on Lynn channel and in other portions of the archipelago. Thence northward to Mt. St. Elias granite and metamorphic rocks skirt the coast. In the Aleutian islands the tertiary formation is of considerable extent, and contains coal, lignite, and amber. The best deposit of tertiary coal, so far as known, is on Cook's inlet, where it occurs in two parallel layers, with an estimated

thickness of from 18 inches to 7 feet. Gold and silver are found in Alaska in small quantities; and copper is frequently brought to the settlements by Indians dwelling on the Copper river, who sedulously conceal the locality of its origin. Cinnabar and iron have been found in very limited quantities. Of sulphur the volcanic districts of the territory afford an abundant supply.—The fossils found in Alaska show that it was once the home of the elephant, the buffalo, and the horse. Bears are now the largest animals native to the country. Of these, the polar or white bear (*ursus maritimus*) is met with on the Arctic coast; the black bear (*U. Americanus*) in the woody districts of the Yukon; and the barren-ground bear (*U. Richardsonii*) in the far northeast. The grisly bear (*U. horribilis*) is also occasionally encountered. Of the other non-marine furbearing animals the principal are the fox, the beaver, the marten, the otter, the mink, the lynx, and the wolverene. On the coasts are found the fur seal, the main source of revenue in the territory; the sea lion, closely allied to the former; the sea otter, an animal of solitary habits living almost exclusively in the water; and the walrus, from which the natives obtain their ivory and oil. In the adjacent seas whales are abundant, and cod, herring, and halibut are found in prodigious numbers, at the proper seasons. A small fish called the ulikon, upward of a foot in length and of a silvery hue, is also very abundant along some parts of the coast, and is remarkable as being the fattest of all known fish. The various species of salmon which through the Alaskan rivers occur in numbers so great as almost to exceed belief. The weak and injured fish which die after spawning time are sometimes thrown up along the river banks by the waves, to the depth of three or four feet. Immense quantities of salmon and other river fish are caught and dried. In summer, Alaska is the nesting place of myriads of migratory birds. Geese and ducks, swans, ospreys, eagles, and gulls arrive about the first of May from southern latitudes, and remain till early autumn, when they leave the country to the ptarmigan, the white hawk, and the arctic owl. The rich berries of the interior afford them excellent food. Here the nests of the canvas-back duck, so long sought for in vain in other regions, were first discovered. Mosquitoes abound during the summer months along the Yukon valley. Beetles and several varieties of butterfly are known to occur.—The natives of Alaska may properly be classed into two divisions: the Esquimaux and kindred tribes, and the Indians. To the first belong the inhabitants of the Aleutian islands, and the Innuits, who are settled on the islands along the coast from Behring strait to Mt. St. Elias. Their intercourse with the Russians has deprived the Aleuts of all their national characteristics; but they are as yet by no means civilized, though many of them profess the Christianity of the Greek church. Hunt-

ing the fur seal and sea otter is their principal occupation. Of the Indians, the Co-Yukon is the largest tribe on the Yukon river. They dwell during the winter in underground huts, and are greatly feared by the surrounding natives of other tribes, on account of their fiercer nature and superior prowess.—The fisheries and the fur trade are the leading industries of the territory. In 1870 the product of the fishery, in salted codfish alone, was 10,612,000 lbs. The taking of fur seals, which is for the most part restricted to the Pribyloff islands, is now regulated by act of congress, the privilege being under rental to a corporation at \$55,000 per annum. The yield has been much diminished by the unwise and indiscriminate slaughter permitted in past years, but under the present regulations a steady production of 100,000 skins per annum can probably be secured. In 1869, 85,901 seals were taken on St. George's and St. Paul's. The average annual yield of the sea-otter skins is 1,300, and they are worth \$100 each. In 1867-'8 furs to the amount of \$100,000 were produced by the Yukon district, and the average product is not less than \$75,000 worth per annum. The total annual yield of furs from the rest of the continental portion of Alaska does not exceed \$10,000 in value. There is a small trade in ice with California, and timber is exported in limited quantities. A large proportion of the whale oil and bone taken by the Behring sea whaling fleets is derived from Alaskan waters.—Russia acquired her American possessions by virtue of the right of discovery. On July 18, 1741, Vitus Behring, the celebrated Russian explorer, discovered the rocky range of mountains, the crowning peak of which is Mt. St. Elias. Subsequently, and during the same voyage, he visited many of the Aleutian islands, until finally he was overtaken by death at that which bears his name. In 1778 Captain Cook, the English navigator, explored the Alaskan coast, and sailed far up into the bay now known as Cook's inlet, in hopes that it would prove the northern passage homeward to Great Britain. Numerous Russian commercial expeditions visited the new region, and in 1783 a trading establishment was opened on the island of Kadiak. Similar enterprises followed in other localities; and in 1799 the Russian-American fur company was organized under sanction of the emperor Paul, by a consolidation of all the companies then existing in the territory. This corporation was granted the exclusive right of hunting and fishing in the American dominion of the czar. It established a line of forts and trading posts along the coast from Norton sound southward, with occasional stations further inland, and after Sitka was founded the headquarters were removed from Kadiak to that place. The country was ruled by the company, the chief director of which exercised absolute sway throughout the colony till 1862, when, the charter having expired, the government declined to renew it,

in consequence of the abuses which had grown up. The company, however, continued in control by permission of the home authorities. In 1865-7 the territory was explored by a scientific corps sent out from the United States to select a route for the Russo-American telegraph line, a project which was abandoned in consequence of the successful laying of the Atlantic cables. Negotiations were begun in 1867 for the purchase of the country by the United States; \$7,200,000 was the price agreed to be paid, and the treaty was ratified by the senate on May 20 of the same year. On Oct. 18 Brig. Gen. Lovell H. Rousseau of the United States army, having been appointed commissioner for that purpose, formally took possession of the territory in the name of the United States. Alaska constitutes a military and collection district, with headquarters at Sitka.— See "Travels and Adventures in Alaska," by Frederick Whympster (London, 1869), and "Alaska and its Resources," by W. H. Dall (Boston, 1870).

ALAVA, one of the Basque provinces of Spain, separated from Old Castile on the S. W. by the Ebro, and from Biscay and Guipuzcoa on the N. by mountain ranges; area, 1,203 sq. m.; pop. in 1867 (estimated), 102,000. The mountains ramify over the whole province, and yield a great variety of minerals, stone, and timber. There are numerous mineral springs. The soil is most fertile along the Ebro, in the Rioja Alavesa, where chiefly wine and fruits are produced; and in the other valleys abundance of maize, hemp, and garden fruits are raised. The inhabitants are almost exclusively Basques. (See **BASQUES**.) The chief towns are Vitoria, the capital, Orduña, Treviño, and Salvatierra.

ALB, a vestment of white linen or linen and lace, reaching to the feet, and bound around the waist by a cincture, worn by sub-deacons and all the superior orders of the clergy in the Roman Catholic church, while officiating in the more solemn functions of divine service.

ALBA, a city of Italy, province of Cuneo, on the Tanaro, 33 m. S. S. E. of Turin; pop. about 10,000. It is a bishop's see, and has an ancient cathedral. There is a large trade in cattle.

ALBACETE. **I.** A S. E. province of Spain, forming a part of the old kingdom of Murcia; area, 5,965 sq. m.; pop. in 1867 (estimated), 221,000. Large portions of the province are level, and the soil is in general very fertile; but the surface is varied, and in the west mountainous. The principal rivers are the Segura, Mundo, and Jucar. The chief towns are Albacete, Almansa, Villarrobledo, Caudete, Alcaráz, Tobarra, Hellin, and Segura. **II.** A city, capital of the preceding province, situated in a fertile plain on the highway and railroad between Madrid and Cartagena, 135 m. (direct) S. E. of Madrid; pop. in 1860, 17,088. The town is well built, and has been called the Sheffield of Spain from its former large business in cutlery; but the manufacture has greatly declined, and the chief productions now are coarse dag-

gers and sword knives (*puñales*). There is a large general trade with other towns.

ALBA LONGA, one of the most ancient cities of Latium, and the mother of Rome, was, according to the Roman legends, built by Ascanius or Iulus, the son of Æneas. It is said to have been called Alba from a white sow found in its vicinity by Æneas, and Longa from its form. Its last kings of the Ascanian line were Numitor, the grandfather of Romulus, and Amulius. The Curatii fought for its independence and supremacy against the Horatii of Rome. It was destroyed by Tullus Hostilius, except the temples, and its inhabitants were removed to Rome about 650 B. C. Strabo says it stood on the declivity of Mount Albanus, east of the lake of the same name.

ALBAN, **Saint**, said to have been the first martyr for Christianity in Britain. He was born in the town of Verulamium, went to Rome in company with Amphibalus, a monk of Caerleon, became a Christian, and returned after serving seven years in the Roman army. It is generally believed that he suffered martyrdom at the time of the persecution of Diocletian, but authorities differ as to the precise date. Bede fixes it at 286; Usher reckons it among the events of 303. About 400 or 500 years after his martyrdom, Offa, king of the Mercians, built a large monastery in honor of him. Around this monastery grew up the present town of St. Albans in Hertfordshire.

ALBANENSES, the name given by some writers to that division of the Catharists who believed in an absolute dualism, in opposition to the Concorrezenses and Bagnolenses, who believed in one supreme principle. The name is derived from the town of Alba, on the Tanaro, in Piedmont, where the sect had one of its chief communities. Another community was at Donzéchum (probably Donzenac) in southern France; after which place it was also sometimes called. (See **CATHARISTS**.)

ALBANI, or **Albano**, **Francesco**, an Italian painter, born in Bologna, March 17, 1578, died Oct. 4, 1660. He studied under Denis Calvaert and Ludovico Carracci. His frescos in the national church of the Spaniards in Rome brought him into notice. His fame is chiefly founded upon his smaller paintings. He loved to paint pleasant landscapes, Venus and Cupid, young girls and children, his own 12 children by his beautiful second wife serving him as models for his finest figures.

ALBANIA, in ancient geography, a country of Asia, bordering on the Caspian sea, and bounded W. by Iberia, N. by the Ceraunian branch of the Caucasus, and S. by the Cyrus (Kur) and the Araxes (Aras). It comprised portions of modern Daghestan, Lesghistan, and Shirvan. Its inhabitants were a handsome and warlike people, of Scythic race, probably identical with the Alani. They brought a formidable army into the field against Pompey. Though often defeated, they were never subdued by the Romans.

ALBANIA (called by the natives *Shkipëria*, and by the Turks *Arnautlik*), a province of European Turkey, between lat. 39° and 43° N. and lon. 19° and 21° 30' E., extending for about 290 miles along the Adriatic and Ionian seas, and having a breadth in the centre and parts of the north of upward of 100 miles, and in the south, near the gulf of Arta, of not more than 40 miles. It is bounded on the N. by Montenegro and Bosnia, on the E. by Turkish Servia, Macedonia, and Thessaly, and on the S. by the modern kingdom of Greece. Pop. estimated at 2,000,000. Albania embraces ancient Epirus, Illyris Græca, and the adjoining parts of ancient Dalmatia. The ridge of mountains anciently chiefly known as the Scardus and the Pindus forms its ill-defined northern and eastern boundary. The general character of the country is rugged and mountainous. Nine ranges of hills intersect it from N. E. to S. W., with elevations of from 4,000

Albanian Costume.

to 8,000 feet above the sea, and covered with snow three fourths of the year. The rivers are inconsiderable, and many of them during the summer are quite or nearly dry; the most important are the Drin and the Voyutza. There are several lakes, among them those of Scutari, Ochrida, and Janina. In the mountains and forests there are bears, wolves, wild hogs, and deer; sheep, goats, and cows are tended in the valleys; and there is an excellent breed of horses. Eagles and various kinds of birds are plentiful, and hawking is the favorite amusement of the wealthy classes. The varied vegetation exhibits many forms similar to those of the Swiss Alps and the mountains of Scotland. The exports of Albania consist of oil, wool, maize, tobacco, horses, sheep, goats, timber, and some embroidered velvets and cloths. Merchandise is carried inland by means of pack horses, four or five of which

are attached together by cords and guided by one man. The vigorous administration of Ali Pasha, by building roads and suppressing gangs of robbers, added much to the facility of internal traffic.—Lower or southern Albania constitutes the cyalet of Janina, and upper Albania comprises the greater part of the divisions of Pristrend, Monastir, and Scutari. Among the most remarkable tribes is that of the Mirdites in the north, whose territory has never been invaded by the Turks, and who acknowledge no subjection to the Porte, except in supplying a contingent to the army in case of war. The Albanians are muscular, active, and erect. The women are tall and strong, with an air indicating ill treatment and laborious work. The dress of the people is fantastic and complicated. The wealthy Albanian wears over a close-fitting vest, buttoned to the throat, an open jacket, with open sleeves, richly embroidered. A frilled skirt falls to his knees from a broad girdle, in which are stuck his silver-mounted pistols, on the ornamentation of which he spends extravagant sums, and his yataghan. Cloth leggings, likewise embroidered, cover the legs, and he wears the fez. A peculiar garment, assumed when travelling, is the capote, a cloak of wool or horse-hair. The Albanians are a nation of warriors, early trained to discipline, and constituting the best soldiers in the Turkish army. Their national name is Shkipetars; the Turks call them Arnauts. Wallachs and Greeks live scattered among them. A rude kind of Mohammedanism has gradually supplanted the Christianity of the country.—Though Albania has several times changed its name, its masters, and its boundaries, a people cherishing unchanged their nationality, language, and manners have from the earliest records of history occupied its mountains. First, the fierce tribes of Epirus and the still more savage Illyrians had possession of the country, and withstood alike the efforts of the Greeks and of the Romans to civilize them. On the conquest of Constantinople by the Latins in 1204, one of the imperial family of Comnenus succeeded in establishing a dynasty in this district, and the despots of Albania continued for two centuries only second in power to the emperors of Constantinople. Mohammed II., having conquered Constantinople, marched against the Albanians, only to experience a succession of defeats. The heroism of George Castrioti, commonly known in history as Scanderbeg or Iskander, their last independent prince, resisted for more than 20 years the whole force of the Ottoman empire, and it was not till his death in 1467 that Albania was annexed to the Turkish dominions. Albania was divided into several distinct pashalics till the close of last century, when Ali Pasha, having married the daughter of the principal chief, succeeded in establishing himself as an independent sovereign over all its territory, and a wide extent beyond. After his overthrow, and during the insurrection of the Greeks, the

Albanians were inclined to make common cause with the latter; but their attempts to coöperate in the war produced only their massacre and harsh treatment by the Greeks, and they were therefore thrown into the arms of the Porte, to which they have since continued nominally subject.—The Albanian language belongs to the Indo-European family of languages, and is spoken in different dialects in the north and south. The original stock of words is believed to have been derived from the ancient Illyrians, but it is mixed up with Greek, Latin, Turkish, Italian, French, and Slavic. Many of the Albanians, particularly the Toskaris in the south, speak the modern Greek, and in that part of the country the Albanian proper is also more mixed with Greek than the Geg dialect in the north. Xylander and Bopp have written on the Albanian language. The work of the latter, *Ueber das Albanesische*, was published in Berlin in 1855. Both the Latin and Greek alphabets are used in Albanian books. Latin letters have been adopted in the translation of the New Testament (Constantinople, 1866), and in versions from the gospel of St. Matthew by Prince Louis Lucien Bonaparte, with occasional Greek letters, and in other contemporary works. Greek letters have been used by Anastasio Kulurioti (Athens, 1866), by Salterio (Constantinople, 1868), and in the *Alfabeto generale Albano-Epirotico* (Leghorn, 1869), which last is also contained in *A Dora d'Istria gli Albanesi* (Leghorn, 1870). An Albanian grammar has been lately published at Leghorn (*Grammatologia Albanese*). Prince Louis Lucien Bonaparte's version of the parable of the sower in Matthew has been published under his auspices in the Siculo-Albanese, the Calabro-Albanese, and the Scutari-Albanese dialects (London, 1868-'70). Albanian literature consists chiefly of popular songs and fairy tales. The late Austrian consul at Syra, Mr. de Hahn, is a high authority on the subject in his *Albanesische Studien* (Jena, 1854), and *Griechisch-Albanesische Märchen* (2 vols., Leipsic, 1864). Dora d'Istria, the author of the "Mussulman and Roumanian Albanians," has in other recent publications thrown much light upon the Albanian language and poetry.

ALBANO (anc. *Albanum*), a city of Italy, in the province of Rome, near the southern extremity of Lake Albano, 14 m. S. E. of Rome; pop. 5,200. It occupies the site of Pompey's villa, and is on the opposite side of the lake to that of ancient Alba Longa. It is a favorite summer resort of the Roman nobility on account of its beautiful scenery and pure air. It possesses a museum of antiquities and many fine ruins. The Albano wine, which is made in the vicinity, was already famous among the ancient Romans. The lake of Albano, or Lago di Castello, is in the crater of an extinct volcano, and is surrounded by huge basaltic rocks.

ALBANY. **J.** An E. county of New York, bounded E. by the Hudson river and N. in part

by the Mohawk; area, 509 sq. m.; pop. in 1870, 133,052. Normanskill and Catskill creeks furnish it with good water power. The land near the Hudson and some of the other streams is fertile; but in the N. and W., where the surface is mountainous, it is less productive, and in some places sterile. The E. part is covered with immense beds of clay, sand, and gravel, the sand in some places being 40 feet deep. Iron, hydraulic limestone, marl, and gypsum are found, though they are not abundant. The productions in 1870 were 14,859 bushels of wheat, 129,535 of rye, 165,350 of corn, 784,146 of oats, 37,205 of barley, 160,594 of buckwheat, 637,058 of potatoes, 115,655 tons of hay, 137,641 lbs. of wool, 1,142,783 of butter, and 133,964 of hops. In 1865 the value of farms was \$16,951,183, of stock \$1,820,376, and of tools \$97,486. There were 364 manufacturing establishments, employing 9,292 hands, 130 churches, 18 newspapers and periodicals, and 7 savings banks. The Erie and Champlain canals and several railroads terminate in this county. The assessed value of real estate in 1870 was \$38,557,176, and of personal property \$7,535,171. Besides Albany, the capital, Cohoes and West Troy are important manufacturing places. Albany county was organized in 1683, and originally extended E. of the Hudson, and included the whole colony N. and W. of its present limits. **H.** An E. county of Wyoming, occupying the whole width of the territory, about 265 m.; area, about 12,000 sq. m.; pop. in 1870, 2,021. The Union Pacific railroad passes through the S. part of the county. Capital, Laramie.

ALBANY, a city, capital of Albany county and of the state of New York, at the head of sloop navigation and near the head of tide water, on the W. bank of the Hudson river, in lat. 42° 39' 3" N., lon. 73° 32' W., 145 m. N. of New York city, 164 m. W. of Boston, and 370 m. N. E. of Washington. According to the official censuses, the population of Albany in 1790 was 3,506; in 1800, 5,349; 1810, 10,762; 1820, 12,541; 1830, 24,238; 1840, 33,762; 1850, 50,762; 1855, 57,333; 1860, 62,367; 1865, 62,613; 1870, 69,422. But the population now (1873) is probably not far from 80,000, as the boundaries have been enlarged by the addition of parts of Bethlehem and Watervliet, and the territory now comprised within the city limits had in 1870 a population of 76,216. At a little distance from the river the ground rises into a plateau about 200 feet above tide level, and then extends westward in a sandy plain. The slope toward the river is divided into four distinct ridges, separated by valleys, which were originally deep and difficult to cross; but these have been much improved by grading, and within a mile from the river nearly disappear. The tide rises about one foot in the river here. Notwithstanding the occasional obstruction of navigation by the "overslaugh" (see HUDSON RIVER), Albany is peculiarly favored as a commercial town.

View of Albany from Greenbush.

The Erie canal terminates in a basin here, and the New York Central and Hudson River railroad passes through the northern border of the city, crossing the Hudson river upon a bridge. The Albany and Susquehanna railroad extends to Binghamton on the Erie railway; the Albany and Vermont railroad connects with lines to Vermont and Canada; and the Boston and Albany railroad terminates on the opposite side of the river. The extension of the Walkill Valley railroad to Albany was permitted in 1870, and a railroad on the west shore of the Hudson southward has been proposed, but neither has yet been built. A road is also projected from opposite Albany to Sand Lake. The Hudson river bridge, built of timber, was opened Feb. 22, 1866. It has 21 piers, a draw which leaves an open passage 110 ft. wide on each side when turned, 4 spans of 172 ft., and 14 of 72 ft. each. It is 1,953 ft. long, and including the approaches 4,253 ft., and cost with real estate, &c., about \$1,100,000. The bridge company, consisting of the railroads in interest, having been authorized to construct a new bridge near the foot of Exchange street, while retaining the former, it was commenced in May, 1870, and finished Jan. 1, 1872. It is an iron truss bridge, 1,014 ft. long and 30 ft. above the water, with 11 spans and a draw of 274 ft. It is used only for foot passengers and passenger trains, while the former is used for freight. —The old state capitol, a plain brown stone structure built in 1807 for \$173,000, is still occupied, but will be demolished as soon as the costly new capitol is finished. In 1865 an act was passed authorizing the erection of a new capitol, on condition that the city of Albany should give to the state for the purpose the

ground commonly known as the Congress Hall block, extending from State street to Washington avenue, immediately in the rear of the old capitol. In 1867 the first appropriation of \$250,000 was made for the building, and the corner stone was laid June 24, 1871. The material is Maine granite, and the edifice will be the largest and most splendid in America, excepting the federal capitol at Washington. The ultimate cost can only be conjectured, but up to Jan. 1, 1872, when the foundation and basement story only had been erected, the expenditure already amounted to \$2,037,670 41. The state library, a handsome fire-proof building fronting on State street, in rear of the old capitol, contains 86,000 volumes; its law section is the strongest and best. In February, 1872, congress appropriated \$350,000 for a building in Albany to accommodate the United States courts, post office, custom house officials, &c., the city giving the site.—Among the state institutions are the geological and agricultural hall, and a state normal school established in 1844 for educating teachers in common schools. The state hall on Eagle street, built of white marble in 1843 at a cost of \$350,000, contains the offices of the secretary of state, attorney general, comptroller, treasurer, canal board, superintendent of public instruction, &c. The city hall, on Eagle street, foot of Washington avenue, a beautiful structure of white marble, was finished in 1832. It is 100 ft. front by 80 deep, three stories high, and has in front a recessed porch in the second and third stories, supported by six Ionic columns. In 1869-'70 a new city building was erected on S. Pearl street at a cost of \$200,000, and is used by the police and civil justices' courts, fire and police

departments, park commissioners, assessors, &c. Among the local institutions most worthy of note are the merchants' exchange, the Dudley observatory, the Albany medical college, the law school of the university of Albany, the city hospital, the St. Peter's hospital, the Albany and the St. Vincent orphan asylums, the city dispensary, the home of the friendless, the Albany institute, the young men's association, the young men's Christian association, the Albany academy, the Albany female academy, the academy of the Sacred Heart, and the academy of the Christian Brothers. The Dudley observatory, named after Charles E. Dudley, once mayor of Albany and United States

senator, and founded by the gifts of his widow (Mrs. Blandina Dudley) and others, was incorporated in 1852 and dedicated in 1856. It has a valuable special library, a 13-inch equatorial instrument, a meridian circle, a transit instrument, a calculating and printing engine (the only one in the country), and self-recording meteorological instruments of many kinds. It gives exact time by telegraph to the city and to various railroads. The young men's association, formed in 1833, supports a lecture course during the winter, and has a library of above 12,000 volumes, and a reading room supplied with 75 papers and 30 other periodicals. It is the oldest institution of the kind in the United

The New Capitol at Albany, N. Y.

States, and has about 1,100 members. There are 54 churches: Baptist, 5; Congregational, 2; Protestant Episcopal, 6; Evangelical, 2; Friends', 1; Jewish, 3; Evangelical Lutheran, 4; Methodist Episcopal, 8; Presbyterian, 6; Reformed Protestant Dutch, 6; Roman Catholic, 10; and United Presbyterian, 1. A Reformed Protestant Dutch church was formed in 1640, and a quaint edifice of this order stood in State street at Broadway till 1806. A Lutheran church was formed in 1680, a Protestant Episcopal in 1715, and a Roman Catholic society in 1796. The communion plate of St. Peter's church was presented by Queen Anne for the Onondaga Indians. The number of

public schools is 16, of which one is for colored children; there is also a free academy with 8 teachers and 214 pupils. The penitentiary, situated on the west of the city, about a mile from the capitol, was built in 1845-'6, and has 600 cells. At the close of 1871 there were about 500 convicts, a large number of whom were prisoners of the United States. The contract system of labor is adopted, the men being employed in shoemaking and the women in chair-seating. The income exceeds the expenditure by a sum varying from \$10,000 to \$20,000 a year, while in all the other penitentiaries of the state there is an annual deficiency of from \$50,000 to \$125,000. There are no pun-

ishments for refractory prisoners except confinement in a solitary cell. School is kept for those who choose to attend on two evenings of the week, and there is a library of 1,400 volumes. In 1869 the old burial grounds, penitentiary grounds, almshouse farm, and Washington parade ground, in the western part of the city, were set apart for a public park, to be known as "Washington Park."—For 30 years after the revolution, Albany was the seat of the entire trade of the western part of the state, the produce being brought in by sleighs in winter; but the growth of the city was not rapid. The first great impulse to its commercial prosperity was given by the successful trip of the Clermont, the first steamboat of Fulton, in 1807, and the improvements in stean navigation which immediately followed. The steamboats now upon the Hudson river are among the largest that navigate any inland waters. The Erie canal, completed in 1825, and the various lines of railroad constructed since that time, have each essentially added to the growth and prosperity of the city. The total amount of property reaching tide water at Albany by the Erie and Champlain canals for the year 1871 was 848,829 tons, valued at \$15,806,259; the total cleared from Albany the same year by both canals was 82,079 tons, valued at \$4,753,971; and the amount of canal tolls collected at this place was \$2,837,077. The total number of cars of grain inspected at Albany in 1871 was 2,595; the sales of grain at the corn exchange here the same year aggregated 3,947,000 bushels. The lumber market of Albany is the largest in the state; the value of the boards, shingles, timber, &c., received here in 1870 was nearly \$10,000,000. There are 32 slips from the river for receiving boats, and a river dock more than a mile long for loading boats and barges. There is also in the river a pier, not connected with the shore, about 1,100 feet long. The Albany board of lumber dealers was incorporated in 1869, and in 1871 there were 57 firms engaged in this trade. The city is the seat of very important and extensive manufactories, of which the most numerous are 9 boiler and steam engine works, 13 boot and shoe factories, 18 breweries, 17 carriage builders, 10 flouring mills, 18 harness factories, 4 piano factories, 18 iron foundries, 17 machine shops, 8 sawing and planing mills, 12 stove foundries, and 11 soap and candle factories, besides extensive factories of car wheels, saws, oilcloth, agricultural implements, jewelry, silver ware, cabinet furniture, &c. The city has 9 banks, 6 savings banks, 6 insurance companies, and 7 daily, 1 tri-weekly, 2 semi-weekly, 5 weekly, and 2 monthly periodicals.—Albany is the oldest settlement in the original 13 colonies except Jamestown, Va. Henry Hudson, in the yacht Half Moon, moored in September, 1609, at a point which is now in Broadway, Albany. Several Dutch navigators ascended the river to the same place during the next three or four years, and in 1614 the Dutch

built the first fort on an island below the present city, which is hence called Castle island. In 1617 a fort was built at the mouth of the Normanskill; and in 1628 another was erected near the present steamboat landing in the south part of the city and named Fort Orange. A quadrangular fort called Fort Frederick was afterward built on the high ground, now State street, between St. Peter's church and the geological hall, with lines of palisades extending down Steuben and Hudson streets to the river. These fortifications were demolished soon after the revolution, and the only evidence of their existence now remaining is the curved outlines which they have given to the streets in the older parts of the city. The place was called by the Dutch New Orange, and retained that name until the whole province passed into possession of the English in 1664, when New Orange was changed to Albany, in honor of the duke of York and Albany, afterward James II. In 1686 Albany city was incorporated by patent. Peter Schuyler was the first mayor. The Schuyler family possessed the good will of the Indians to such a degree that while other settlements were desolated by Indian forays, Albany was never attacked by them. Besides its ancient importance as a centre of the Indian trade, Albany afterward became the point where the great military expeditions against Canada were fitted out. It was fortified at an early period, and although often threatened with invasion, no hostile army ever reached the city. Here assembled the first convention for the union of the colonies. It was held in 1754, and Benjamin Franklin was its leading member. The ostensible object of this convention was the defence of the colonies against the savages, but the plan of union then drawn up and adopted was the first recorded in the history of the country. Albany became the state capital in 1797. It has been visited by several disastrous fires, of which those in 1797 and 1848 were most destructive. The lower part of the town has often been inundated.

ALBANY, an eastern district of Cape Colony, on the coast, traversed by the Sneeuw (snow) mountains and some other ranges, and by the Great Fish river; area, 1,792 sq. m.: pop. in 1865, 16,264, including 4,229 Caffres and 1,472 Hottentots. The surface is undulating, and the scenery varies from rugged heights to pleasant plains. The climate is healthy. The soil produces wheat, maize, barley, oats, and cotton. A chief occupation of the settlers is stock raising. Capital, Graham's Town.

ALBANY, Louise Marie Caroline Hélcise, countess of, wife of the last of the Stuarts, and celebrated for her association with the poet Alfieri, born in Mons, Belgium, Sept. 20, 1753, died in Florence, Jan. 29, 1824. She was a daughter of Prince Gustavus Adolphus of Stolberg-Gedern, who fell in the battle of Leuthen. In 1772 she became the wife of Charles Edward Stuart, grandson of James II., and pretender to the British crown, known as the count of Al-

bany, who was her senior by 33 years. The marriage was said to have been arranged with the hope of menacing the English sovereign with a legitimate heir to the rival Stuart dynasty. It proved most unhappy. She was young, refined, intellectual; he old, coarse, and intemperate. They lived at Florence, where she became acquainted with the poet Alfieri, who conceived a passionate regard for her. It was under her guidance that he began to write his tragedies. She was never charged with infidelity to her husband, whose brutality, however, became so unendurable that she left him, and sought refuge in a Florentine and subsequently in a Roman convent. In 1783 she obtained a formal separation from him through the interposition of Gustavus III. of Sweden, who also procured for her a pension from the French government, which was withdrawn after the outbreak of the revolution. About a year after her husband's death (1788) the countess is said to have been secretly married to Alfieri, but they never appeared in public as husband and wife, though he was constantly in her society at Paris, London, and Florence, where she was received with distinction in the highest circles. In Florence her social and political influence was so great that Napoleon dreaded it almost as much as that of Mme. de Staël and of Mme. Récamier, especially in view of Alfieri's opposition to his rule. After the death of Alfieri (1803) the countess resided chiefly at Florence, where she is said to have formed an intimate relation with François Xavier Favre, a French painter. Alfieri says in his autobiography that without her inspiring influence he would have achieved nothing. She was buried in the church of Santa Croce at Florence, in the same tomb with Alfieri, which is adorned with a monument by Canova. A biographical work entitled *Die Gräfin von Albany* has been published by Reumont (2 vols., Berlin, 1860).

ALBATEGNIUS, or **Albatagni** (properly **MOHAMMED BEN GEBER ALBATANI**), an Arabian prince and astronomer, died about A. D. 929. He is also called **Muhamedes Aractensis**. His principal astronomical work—mainly an abridgment of the *Almagest* of Ptolemy, though containing many original principles and observations—was translated into Latin by Plato of Tibur, and published at Nuremberg in 1537, and afterward at Bologna in 1645. In the opinion of Lalande, he was one of the 20 most eminent astronomers that ever lived.

ALBATROSS (*diomedea*), a genus of web-footed sea birds, which has three species—the common albatross, *D. exulans*, the albatross of China, *D. fuliginosa*, and the yellow and black-beaked albatross, *D. chlororhynchos*. The genus is distinguished principally by a very strong, hard, straight beak, which suddenly curves downward, with a sharp hook at the point. The feet are short; the three toes long and completely webbed; the wings very long and narrow. The common albatross is the largest

sea bird known, weighing from 12 to 28 lbs. The usual extent of its wings is about 11 feet; but a specimen in the Leverian museum

Albatross (*Diomedea exulans*).

measured 13 feet, and one was shot off the Cape of Good Hope of 17½ feet in extent. The top of its head is ruddy gray; all the rest of its plumage white, with the exception of a few transverse black bands on its back, and a few of the wing feathers. It is abundant from the Southern ocean to Behring strait and the coast of Kamtchatka, frequenting the inner sea about the Kurile islands and the bay of Penshinsk, in vast flocks, but scarcely visiting at all the eastern or American coasts. Its voracity is extreme, and it is said that it will often swallow whole a salmon of four or five pounds weight. Its ordinary food is fish, fish spawn, and small shell fish; but it does not hesitate to take any animal substance found floating on the surface of the waves, and is often taken by sailors with a line and hook baited with a piece of fat pork. Its powers on the wing are extraordinary, as might be presupposed from the extreme lightness of its immense hollow wing bones, which are said by Edwards to be as long as the whole body, and which the Kamtchatdales use as tobacco pipes; and from the great height, power, and continuance of its flight, sailors, who know it generally as the "man-of-war bird," among other strange notions, believe that it sleeps on the wing.

AL-BELADORI, **Abul Hassan Ahmed**, an Arabian historian, died about 895. He was minister of religion at Bagdad, resided at the court of the caliph Motawakkel, and was intrusted with the education of one of the princes of the caliph's family. He wrote a work giving the history of the conquest of Syria, Cyprus, Mesopotamia, Armenia, Egypt, Nubia, northern Africa, Spain, and the Mediterranean islands, and an account of the spread of the Mohammedan religion over Persia, Transoxiana, and the countries on the shores of the Indus.

ALBEMARLE, a central county of Virginia, bounded N. W. by the Blue Ridge mountains and S. by the James river, and watered by its branches; area, 700 sq. m.; pop. in 1870, 27,544, of whom 14,994 were colored. The surface is undulating, soil very rich in the valleys and river bottoms, and the scenery picturesque.

The productions in 1870 were 218,545 bushels of wheat, 384,851 of corn, 180,461 of oats, and 1,781,619 lbs. of tobacco. The Chesapeake and Ohio and Orange, Alexandria, and Manassas railroads intersect at the capital, Charlottesville.

ALBEMARLE SOUND, a large inlet of the sea on the northern part of the coast of North Carolina, extending 60 m. into the country, and having a width of from 4 to 15 m. It is separated from the sea by a narrow island, is not affected by the tides, receives the waters of the Roanoke and Chowan rivers, and is nearly fresh. It has connection with Currituck and Pamlico sounds by inlets, and with Chesapeake bay by a canal cut through the Great Dismal swamp. This sound has not a great depth of water, and is of comparatively little value for commercial purposes.

ALBERGATI-CAPACELLI, Francesco, marchese d', an Italian dramatic writer and actor, born in Bologna, April 29, 1728, died March 16, 1804. He has been called the Garrick of Italy. His youth was wasted in debauchery, but at the age of 40 he had acquired a high reputation by his dramatic compositions, and as a wit and actor. His works appeared in 12 vols. (Venice, 1783-'5), and 6 vols. (Bologna, 1784).

ALBERIC I., a ruler of Rome in the early part of the 10th century. He was originally a Lombard nobleman, but obtained through the aid of Berengarius of Friuli the marquisate of Camerino, and by his marriage with Marozia, the daughter of the notorious Roman Theodora, the temporal authority over Rome. He joined Pope John X. in the expulsion of the Saracens. He also ruled the duchy of Spoleto. He was, however, banished from Rome, and finally murdered in 925. His widow wedded Guido of Tuscany, and after his death Hugo of Provence, king of Italy, who was afterward expelled by her son, **ALBERIC II.**, who reigned over Rome until his death in 954.

ALBERONI, Giulio, a Spanish statesman, born near Piacenza, Italy, May 31, 1664, died in Rome, June 16, 1752. He was the son of a vine-dresser, and was brought up to the church. In the war of the Spanish succession he gained the favor of the duke of Vendôme, commanding the French troops in Italy, and accompanied him to Paris in 1706, and to Spain in 1711, acting as his secretary. In 1713 he was appointed envoy of the duke of Parma at the Spanish court. He was befriended by the celebrated Princess Orsini; but, having induced her to employ him in negotiating the marriage of Philip V. with Elizabeth Farnese of Parma, his first act after the queen's arrival was to urge her to apply for the dismissal of the princess, who was at once arrested and banished. He became prime minister of Spain in 1714, and in 1717 was made a cardinal by Clement XI. His internal administration was distinguished for economy, the encouragement of industry, and the development of the resources of Spain. He remodelled the army, rebuilt the fleet, strengthened the defences, and increased the

foreign commerce. But the ambition of restoring Spain to her former greatness, seconded by the queen's ambition for the aggrandizement of her family, prompted him to a violent foreign policy. He seized on Sardinia in a time of peace (1717), invaded Sicily (1718), entered into adventurous schemes with Charles XII., Peter the Great, and the Stuarts against France and England, plotted a conspiracy to depose the regent Orleans, and embroiled Spain with all the other powers of Europe, bringing about the quadruple alliance of England, France, Austria, and Holland. Alberoni's courage rose with the danger, and he bade defiance to all his enemies at once. The foreign alliance and the hatred of the grandees at home, however, hurled him from place. Peace was concluded in 1719, one of the stipulations of which was Alberoni's dismissal, and he was ordered to quit Spain without delay. He fled to Italy, whither his foes pursued him, and induced Clement XI. to issue a warrant for his arrest. This he managed to escape, wandering about in circumstances of danger and privation; but on the pope's death (1721) he appeared at Rome in the conclave, and assisted at the election of Innocent XIII., who refused to molest him. He was afterward sent as legate into the Romagna, and finally retired to his native state, where he died at the age of 88. He left a number of MSS., from which his "Political Testament" was published at Lausanne in 1753.

ALBERS, Johann Friedrich Hermann, a German physician, born at Dorsten, Nov. 14, 1805, died in Bonn, May 12, 1867. He practised several years as assistant physician, afterward delivered lectures on pathology at Bonn, and in 1831 was appointed professor there. He also established at Bonn a private hospital for mental and nervous diseases. He is the author of an "Anatomical Atlas" (287 plates, with text, 1832-'62), and works on general pathology, pharmacology, diseases of the larynx, syphilitic skin diseases, &c.

ALBERT, a S. E. county of the province of New Brunswick, Canada, bounded S. and S. E. by the bay of Fundy and Chignecto bay; area, 677 sq. m.; pop. in 1871, 10,672. The land is good, and there are extensively diked marshes, mines of bituminous and cannel coal, oil-bearing shales, plaster beds, and quarries of freestone. The coal and plaster are taken by a horse railroad to Hillsborough, respectively 2½ and 5½ m., and shipped principally to the United States. Petroleum was at one time largely produced. Chief town, Hopewell.

ALBERT, the pseudonyme of ALEXANDRE MARTIN, a member of the French provisional government of 1848, born at Bury, department of Oise, April 27, 1815. He was a maker of mechanical models, and continued to work at his trade after he became prominent as an agitator, and in 1840 as founder of a revolutionary journal entitled *L'Atelier*, written by working men exclusively. A friend of Louis Blanc, he

became a member of the provisional government as a special representative of the working classes, and always signed himself "Albert, ouvrier." He was elected to the constituent assembly for the department of the Seine; but being implicated in the uprising of May 15, he was sentenced to transportation, and remained in prison till the amnesty of 1854. Albert does not figure in the history of the Commune of 1871.

ALBERT I. (Ger. *Albrecht*), archduke of Austria and emperor of Germany, born in 1248, died May 1, 1308. He was the son of Rudolph of Hapsburg, and succeeded to his hereditary estates, but the succession to the crown was conferred by the electors upon Adolphus of Nassau. Albert affected submission, and remitted to the new emperor the royal insignia. But on the coronation of Wenceslas of Bohemia he met four of the electors, and arranged with them a diet at Mentz, before which Adolphus was summoned to answer charges of high crimes and misdemeanors. Adolphus of course refused the requisition of any such tribunal, and the diet thereupon adjudged him guilty of contumacy, and deprived him of the crown. War was declared, the two armies met, July 2, 1298, near Gellheim, between Spire and Worms, and Albert unhorsed Adolphus in personal combat, whereupon the latter, continuing to fight, was soon despatched by the followers of his rival. Feigning a respect for the rights of the body of electors, Albert declined to exercise the supreme power until a diet had been formally convened, and he was duly elected and crowned at Aix-la-Chapelle. Pope Boniface VIII., however, stigmatized him as a murderer, and instituted a new combination against him, which was disconcerted by Albert's son Rudolph. Albert was now involved in hostilities with Bohemia, of which he made himself master for a short time; but the people rose, and he was obliged to retire. He attempted to subjugate part of Switzerland, but in crossing the river Reuss in a boat was murdered by his nephew John of Hapsburg, whose possessions Albert had seized during his minority. John was assisted by three noblemen. Albert's daughter Agnes terribly avenged her father's murder, though not on John himself, who escaped to Italy, and died a monk. Albert was succeeded in Austria by his son Frederick the Handsome, and in the empire by Henry of Luxemburg.

ALBERT (Ger. *Albrecht*), the first duke of Prussia, son of Frederick, margrave of Anspach and Baireuth, and grandson of Albert Achilles, elector of Brandenburg, born May 17, 1490, died March 21, 1568. He was educated for the church under the elector of Cologne, but also served in the army of the emperor Maximilian, and in 1511 was elected grand master of the Teutonic order. Refusing to take the oath of fealty to the king of Poland, he became involved in the hostilities which had

subsisted for years between the order and the Poles. Sigismund I. of Poland, whose sister was Albert's mother, began the war in earnest, but, after some successful fighting, was in 1521 induced to grant a four years' truce, during which Albert solicited aid from other German princes. He betook himself to Germany, where he was persuaded by Luther to embrace the reformation and change the domains of the order into a temporal principality. At the expiration of the truce the grand master consented to hold the territory of the order as a fief from Poland, and the majority of the knights agreed to hold under Albert. Albert now threw himself heartily into the reformation movement, established new schools, and founded the university of Königsberg. Dissensions on doctrinal points between the professors of his new university involved him in troubles which lasted till his death.

ALBERT (Francis Albert Augustus Charles Emanuel), prince consort of Great Britain, prince of Saxe-Coburg-Gotha, born at Coburg, Aug. 26, 1819, died in Windsor Castle, Dec. 14, 1861. Under the auspices of his father, Duke Ernest of Saxe-Coburg-Gotha, he received a brilliant education, which he perfected by studying at the university of Bonn. In June, 1838, he visited England, and was introduced by King Leopold of Belgium to the young Queen Victoria, who in November, 1839, formally announced to the privy council that she intended to marry Prince Albert. He was naturalized by act of parliament, Jan. 21, 1840, and the marriage was celebrated Feb. 10. An annual allowance of £50,000 was at first proposed, but only £30,000 was voted. The prince was made a field marshal, knight of the garter, and chancellor of the university of Cambridge, and invested with other high titles and functions. As president of the society of arts his æsthetic tastes found ample scope for activity. The crystal palace of 1851, the forerunner of many other expositions of industry and art, was chiefly due to his zeal and enlightened knowledge. His model farm at Windsor gave a powerful impulse toward the establishment of others all over the country. His public spirit was felt in a variety of industrial and charitable undertakings, while in political affairs he exercised a wise influence over the queen without obtrusive intermeddling. Devoted to the education of the royal family, and warmly attached to the queen, he made the domestic life of the court synonymous with virtue and culture. The delicacy of his position as a German prince and as husband of the queen, without political authority, exposed him occasionally to misapprehensions; and in 1855 it was necessary for the ministry to correct in parliament the impressions which had been current in regard to his alleged partiality for alien interests in international questions. Nevertheless, he frequently saved the government from danger by his cool judgment and patriotism. Shortly before his death, during the civil war in the United

States, he was generally believed to have exercised his influence in favor of the Union. He refused the chief command of the English army, which had been proposed to him by Wellington. The title of "his royal highness prince consort" was conferred upon him by letters patent, under the great seal, June 25, 1857, so that in case of his surviving the queen he might act as regent during the minority of the prince of Wales. Victoria mourned his death with almost unexampled pertinacity. A publication in 1857 of Prince Albert's public addresses was succeeded in 1862 by a fuller work of the kind, prepared at the request of the queen. "The Early Years of His Royal Highness the Prince Consort, by Lieut. Gen. the Hon. C. Grey," was published 1867-'8. Queen Victoria's "Leaves from the Journal of our Life in the Highlands, from 1848 to 1861," edited by Arthur Helps (1868), contains interesting allusions to the excellent prince, whose memory has been perpetuated in England by many beautiful monuments.

ALBERT, Friedrich August, crown prince of Saxony, a German general, son of the reigning king John, born in Dresden, April 23, 1828. As the people over whom he is destined to rule are Protestants, while the royal family are Roman Catholics, a Protestant tutor was selected for him in the person of the Saxon historian Dr. von Langenn. In 1848-'9 he took part in the Schleswig-Holstein war. In 1854, after the accession of his father to the throne, he was called upon to preside over the council of state, having previously been a member of the upper chamber. In 1866 he commanded the Saxon army in cooperation with Benedek's Austrian forces against Prussia, and received a decoration for the excellent behavior of his troops. When Saxony was obliged to join the North German confederation and to place the armed forces under the control of Prussia, they were designated as the 12th corps of the North German army under command of Prince Albert, who highly distinguished himself at the battles of Gravelotte (Aug. 18, 1870) and Sedan (Sept. 1). He was rewarded with the Prussian iron cross, and with the rank of North German commander-in-chief over the newly formed 4th army, composed of Prussians and Saxons, at the head of which, after valuable services at the siege, he made his entry into Paris with the emperor and the other princes of Germany. He married in 1853 a princess of the Vasa family.

ALBERT EDWARD, prince of Wales, duke of Saxony, and prince of Coburg-Gotha, heir apparent to the British throne, second child of Queen Victoria and Prince Albert, born in Buckingham palace, London, Nov. 9, 1841. He was created prince of Wales and earl of Chester by letters patent Dec. 8, 1841, and earl of Dublin Jan. 17, 1850. He is duke of Cornwall pursuant to the statute of Edward III., 1337, the annual revenues of the duchy being about £50,000. In conformity with an

act of the Scotch parliament in 1449, he is high steward of Scotland, duke of Rothesay, earl of Carrick, baron of Renfrew, and lord of the isles. He is a general in the army, colonel of the 10th hussars, captain general and colonel of the honorable artillery company, barrister at law and a bencher of the Middle Temple, president of the society of arts and of other societies, and chancellor of the university of Cambridge. In 1860 he visited the United States and Canada, accompanied by the late duke of Newcastle; and on March 10, 1863, he married at Windsor Alexandra, eldest daughter of Christian IX. of Denmark. His eldest son, **ALBERT VICTOR**, was born at Frogmore Lodge, Jan. 8, 1864. In the autumn of 1871 he was seized with a dangerous typhoid fever, which produced much public anxiety; and his convalescence was celebrated with great pomp at St. Paul's cathedral, Feb. 27, 1872.

ALBERTI, Leone Battista, an Italian architect, poet, painter, and sculptor, born in 1404, died in Rome in April, 1472. His essays on painting and sculpture are greatly admired. His most famous work, however, is a treatise *De Re Edificatoria*. As an architect, he was often employed by Pope Nicholas V., and he designed and superintended the erection of many edifices in Florence, Rimini, and Mantua.

ALBERTINELLI, Mariotto, a Florentine painter, born about 1475, died about 1520. He was a friend and pupil of Fra Bartolommeo, and an imitator of his style. There is a beautiful painting by him in the gallery of the Uffizi at Florence, representing the visitation of Mary and Elizabeth. Fine pictures of his are found in Florence and Munich, and in the Louvre.

ALBERT N'YANZA. See N'YANZA.

ALBERTUS MAGNUS (ALBERT THE GREAT), a scholar of the 13th century. He was of a noble Swabian family, studied at Padua, and entered the Dominican order. He was employed as a teacher in various schools, especially at Cologne. In 1254 he was appointed provincial of his order in Germany, and in 1260 bishop of Ratisbon. In 1262 he returned to his convent, and died there in 1280. He was perhaps the most learned man that the middle ages produced. The titles of his works fill many pages in catalogues, and all branches of human knowledge, theology, philosophy, natural history, physics, astronomy, and alchemy, are represented in them. He devoted himself especially to the study of Aristotle and of the Arab philosophy. His contemporaries, marvelling at his learning, regarded him as a magician, and he became the subject of many legendary stories. But his works prove that he had more patience than genius; he accumulates citations from his immense reading almost by chance, and settles vital problems by carefully balancing the weight of authorities. He had numerous disciples (of whom Thomas Aquinas was the most distinguished), called Albertists, who propagated his doctrines, and confirmed the vogue of Aristotle during the middle ages.

ALBI, or *Alby* (anc. *Albiga*), a town of France, capital of the department of Tarn, on the Tarn, 41 m. N. E. of Toulouse; pop. in 1866, 16,596. It has a cathedral, a museum, and a library, but is one of the least attractive towns of France. The name of the sect of Albigenes was derived from this place and its district, Albigeois. A council denouncing their tenets was held near here in 1176. Albi was one of the most important Protestant towns during the reign of Louis XIV., and the revocation of the edict of Nantes drove many of its citizens into exile.

ALBIGENSES, the collective name of various sects of heretics in the 12th and 13th centuries, who left the Catholic church and called themselves Catharists or Cathari (the pure). The word is derived from Albigeois (Albigesium), the territory of the viscount of Albi, the chief protector of the sects. The war against the Albigenes arose in consequence of the murder in 1208 of the papal legate Peter of Castelnau. Pope Innocent III. threw the blame on the heretical nobility of southern France, and in particular upon Raymond VI. of Toulouse, and had a crusade preached against them. Raymond averted the blow by submitting to the most humiliating conditions, and the crusading army, under the leadership of the legates Milo and Arnold, marched first against Raymond Roger, the viscount of Albi, Béziers, Carcassonne, and Rasez, whose land was devastated and given to Simon de Montfort. When Béziers, the capital of Roger, was taken by storm, 20,000 of the inhabitants were massacred. The army then (1211) turned against Raymond of Toulouse, who had again been excommunicated. His land was also conquered, and in 1215 adjudged to Simon de Montfort. Raymond, however, supported by his subjects, continued a vigorous resistance to Simon, who in 1218 fell at the siege of Toulouse. A large portion of his territory was then reconquered by Raymond, and his son Raymond VII. even succeeded in forcing Amalric, the son of Simon, to a complete surrender. Louis VIII. of France, who was now prevailed upon by Pope Honorius to take arms against the Albigenes, died in November, 1226; but finally Raymond was compelled in 1229 to purchase relief from excommunication by ceding part of his territory to France, and by making his son-in-law, the brother-in-law of Louis IX. of France, heir to the remainder. Thus the Albigenes were left without a patron, and the inquisition was organized in 1229 by the council of Toulouse to complete their extermination. The name maintained itself, however, throughout the 13th century, not only in France, but also in upper Italy, Spain, and other countries, and disappeared at the beginning of the 14th century. For the doctrine of the Albigenes see **CATHARISTS**.

ALBINOS, individuals in whom, by some defect in their organization, the substance which gives color to the skin, hair, and eyes is ab-

sent. These persons, whether Indian, negro, or white, appear of a uniformly dead, milky hue, with hair of the same shade, and eyes with the iris deficient in the black or blue or hazel pigment, which in others conceals the delicate network of blood vessels, and the intense redness they diffuse over the surface. In the albino, both the pupil and the iris lacking this colored curtain, the former, from the concentration within it of fine blood vessels, is of a deep red, and the circle around it is of a pink color. It is supposed that the dark color of the eye and hair is owing to a large quantity of pigmentum in the system, and light hair and eyes to a smaller proportion of it. The name albino was originally applied by the Portuguese to the white negroes they met with on the coast of Africa. With the features of the negro and the peculiar woolly form of the hair, the color of the skin and hair was white. The eye, instead of the jet-black hue, which seems given to the inhabitants of the tropics to enable them to bear the intense glare of the sun, was like that of the white rabbit and ferret, and, like this, better suited for use in the moonlight and in places sheltered from the light of day. From this inability to bear the light, which, however, is said to be much exaggerated, Linnaeus called the albinos nocturnal men. They generally lack the strength of other men; and a peculiar harshness of the skin, such as is noticed in cases of leprosy, would seem to indicate that the phenomenon might result from a diseased organization. They are also deficient in mental capacity. In the same family several children are sometimes born albinos. They are most generally of the male sex. An instance is recorded of a Welsh family, in which every alternate child was an albino. It is stated by Esquirol that two albinos married, and had two children that were not albinos, but of quite brown color. It is not understood to what ultimate cause the phenomenon is to be attributed. It is not limited to man; for individuals possessing the same peculiarities are found among a great variety of the warm-blooded animals, and, according to Geoffroy St. Hilaire, in fishes and some species of molluscous animals as well. Examples are not very rare among the feathered tribe, the effect being seen in the color of the plumage, as in other animals in that of the hair. The white crow and the white blackbird are albinos. Albino mice are not uncommon. The white elephants of India are venerated by the natives, who believe them to be animated with the souls of their ancient kings. One of the kings of the Ashantees is said to have had particular regard for albinos, and collected around him about 100 of them. According to Humboldt, albinos are more common among nations of dark skin, and inhabiting hot climates. In the copper-colored races they are more rare, and still more so among whites.—The knowledge we possess of this subject is derived from the scientific investigations of Blumenbach, De Saussure, who

describes them in his *Voyage dans les Alpes*, Buzzi, surgeon to the hospital at Milan, Sömmering, and others.

ALBINUS (Ger. WEISS), **Bernhard Siegfried**, a German anatomist, born in Frankfort-on-the-Oder, Feb. 24, 1697, died in Leyden, Sept. 7, 1770. He was educated by his father, professor of medicine at Frankfort, and afterward at Leyden, and also studied under Winslow and Senac in Paris. At the age of 22 he was called to fill the office of demonstrator at Leyden, then the most celebrated school of medicine in Europe, and two years later became professor of anatomy and surgery. He published *De Ossibus Corporis Humani*, *Historia Musculorum Hominis*, and lastly, *Tabula Scelleti et Musculorum Corporis Humani* (fol., Leyden, 1747), illustrated with costly plates prepared under his own inspection. He edited the works of Harvey.

ALBION, the appellation by which Great Britain was originally known to the Greeks and Romans. It is a Celtic word, meaning high island or mountain land, and was probably applied originally to the northern part, embracing the Scottish highlands. The root of the word is thus the same as that of the word Alps. The derivation from the Latin *albus*, white, is now rejected by the best critics.

ALBION, a village, the capital of Orleans co., N. Y., about 40 m. N. E. of Buffalo; pop. in 1870, 3,322. The Erie canal and the Niagara Falls and Suspension Bridge branch of the New York Central railroad pass through it. It has several churches, an academy, a female seminary, two or three banks, and two weekly newspapers.

ALBION, New, a name originally bestowed by Sir Francis Drake on the territory now known as California and the adjacent coast, which he visited in June, 1579, but now restricted by Humboldt and other geographers to that part of the N. W. coast lying between lat. 43° and 48° N.

ALBIRCO, a star in the head of the constellation Cygnus. It is one of the double stars, and has lately attracted the especial attention of spectroscopists by the difference in the lines between its two constituents. The primary star is orange, the smaller blue.

ALBOIN, king of the Lombards, succeeded his father in Pannonia about 560, and died in 574. After aiding Narses against the Ostrogoths, and defeating and slaying Cunimond, king of the Gepidæ, he invaded Italy in 568, overran the peninsula as far as the Tiber, and fixed the Lombard capital at Pavia, which he captured after a three years' siege. He had married his prisoner Rosamond, daughter of Cunimond, and at a feast in Verona forced her to drink out of her father's skull; in revenge for which she caused her paramour Helmichis to assassinate him. The guilty pair then fled to Ravenna, where Rosamond poisoned Helmichis in order that she might marry the exarch Longinus. Her victim discovered the treachery and com-

pelled her to die with him. Alboin, in spite of his barbarity, was a beneficent ruler, and is a favorite hero of German poetry.

ALBONI, Marietta, an Italian contralto singer, born at Cesena, March 10, 1826, or, according to some authorities, at Forli in 1824. Her musical education was completed under Rossini, in Bologna, and she made her début at the Scala theatre in Milan. After singing at Vienna, St. Petersburg, and in various parts of Italy and Germany, she reached London and Paris in the year 1847. Her voice was a true contralto of the sweetest and most sonorous quality, extending from F in the bass to C in alt of the soprano—a compass of 2½ octaves. Her favorite parts were in Rossini's *Gazza Ladra*, *La Donna del Lago*, *Semiramide*, and *Cenerentola*, the florid music of which she executed with marvellous ease. In June, 1852, she arrived in New York on a professional tour, and for upward of a year sang in operas, concerts, and oratorios, in the principal cities of this country. In 1869 she sang in Paris in Rossini's posthumous mass, at a salary of 3,000 francs for each performance; and in March, 1872, she reappeared there in opera.

AL-BORAK, the name of the camel on which Mohammed made his imaginary journeys from the temple at Jerusalem to the celestial regions.

ALBORNOZ, Gil Alvarez Carillo, a Spanish prelate and warrior, born in Cuenca, died in Viterbo, Aug. 24, 1367. As archbishop of Toledo, he took part in the contest with the Moors; and having saved the life of Alfonso XI. in the battle of Algeciras, he was ennobled, and in 1343 commanded in the siege of that place. Falling into disgrace with Alfonso's successor, Pedro the Cruel, he fled to Avignon, where Pope Clement VI. created him cardinal. In 1353 Innocent VI. sent him as legate to Italy, to regain for the papacy the control of Rome; and in the course of the years 1353-'62 he succeeded, under the most unfavorable circumstances, in again subjecting the ecclesiastical states to the papal power.

ALBRECHT, Friedrich Rudolph, archduke of Austria, born Aug. 3, 1817. He is the eldest son of the late archduke Charles, second son of the emperor Leopold II., and is consequently first cousin of the reigning emperor's father. He distinguished himself in his youth as a cavalry commander, and had an important share in the battle of Novara in 1849. He was governor general of Hungary 1851-'60. During the campaign of 1866 he commanded the Austrian forces in Venetia, and gained the brilliant victory of Custoza over the Italians (June 24), but the defeat of Benedek at Sadova (July 3) neutralized this success. The archduke was called to replace Benedek, but the treaty of Prague immediately put an end to the war. He is a field marshal, and inspector general of the Austrian army. His wife, daughter of King Louis I. of Bavaria, died in 1864.

ALBRECHTSBERGER, Johann Georg, one of the first modern masters of counterpoint, born in

the neighborhood of Vienna, Feb. 3, 1736, died in that city, May 7, 1809. He was a pupil of the organist Mann. In 1772 he was made court organist, a member of the academy of music, and in 1792 organist in St. Stephen's church in Vienna. Beethoven and Seyfried were his pupils in counterpoint.

ALBRET, an ancient town and castle of Gascony, in a district of the same name, now included in the arrondissement of Mont-de-Marsan, department of Landes. It gave the title of viscount and afterward of duke to an illustrious family, of whom the most distinguished members were JEAN D'ALBRET, who became king of Navarre in 1494 by marriage with the heiress to the crown, and was dispossessed of the Spanish part of his territory by Ferdinand the Catholic in 1512; HENRI D'ALBRET, his son, king of Navarre, who was taken prisoner at Pavia in 1525; and JEANNE D'ALBRET (see ALBRET, JEANNE D'). The site of the town is now occupied by the hamlet of Labrit.

ALBRET, Jeanne d', queen of Navarre, born in Pau, Jan. 7, 1528, died in Paris, June 9, 1572. She was the only daughter of Henry II. of Navarre and Margaret of Angoulême, sister of Francis I. and wife of Antoine de Bourbon, with whom she succeeded on the death of her father to the sovereignty of Lower Navarre and Béarn. She was equally celebrated for her beauty, her intelligence, and her strength of mind. When Pope Paul IV. invested Philip II. of Spain with the sovereignty of Navarre, she formally embraced Calvinism, toward which she had already shown a leaning, while her husband, a man of weak spirit and ignoble impulses, hastened to submit himself to the church, and accepted from Philip the lieutenant-generalship of the kingdom. He applied to the pope to annul his marriage, but died shortly afterward (1562); and Jeanne, despite the intrigues and menaces of Spain and Rome, retained her possessions. In 1567 she declared Calvinism the established religion of the kingdom. With her children Henry and Catharine, she joined Coligny at La Rochelle with a small band of Huguenots in 1569, and after the assassination of the prince of Condé was regarded as the only remaining support of the Protestants. She is extolled by D'Aubigné and other writers for her influence over the Huguenot soldiery. She reluctantly consented to the marriage arranged by Catharine de' Medici and Charles IX. between her son Henry (afterward Henry IV.) and Margaret of Valois, but died before the realization of her misgivings. She wrote both prose and verse; and some of her sonnets were published by Du Bellay.

ALBUCASIS, Bulcasmos, or, properly, **Abulcasim**, an Arabian physician, born near Córdoba, died in that city about 1106. He is known only by his medical work, *Al-Tasriff*, the surgical part of which has been published in Arabic and Latin (2 vols. 4to, Oxford, 1778), and constitutes the most valuable authority upon the surgical science of the Arabs.

ALBUERA, a village of Spain, situated on a river of the same name, in the province and about 12 m. S. S. E. of the town of Badajoz. It was the scene of a battle, May 16, 1811, between Beresford with about 30,000 British, Spanish, and Portuguese troops, who formed the reserve of the army then besieging the French in Badajoz, and Marshal Soult, with 23,000 men, who hoped by defeating the reserve to oblige the British to raise the siege. The attempt was unsuccessful, and the British gained a decisive victory.

ALBUFERA, the name of a lagoon near Valencia, on the E. coast of Spain. It is partly dried up in summer, and a resort for wild fowl, whose capture is a source of revenue. The lagoon, with an estate on its banks, was the domain of Godoy, the prince of the peace. Napoleon created Suchet duke of Albufera, on account of the victory obtained over Blake, and the capture of Valencia, Jan. 9, 1812; and the Spaniards afterward granted the revenues of this district to Wellington.

ALBUMEN (from Lat. *albus*, white, because the albumen of the fowl's egg, on being coagulated by cooking, turns white), an organic substance, more or less fluid in its natural condition, which is coagulated or solidified by the action of heat, alcohol, the mineral acids, and the metallic salts. The characters of albumen were first recognized in the transparent and colorless portion of the contents of the fowl's egg. When an egg is boiled and then opened, it is found to consist of two different portions; namely, an internal portion or yolk, which is yellow, and an external portion, which is white. The external portion before boiling is transparent, semi-fluid, and nearly colorless; and the increased consistency, opacity, and white color which it assumes on cooking, are due to its containing as its principal ingredient the substance in question, which is coagulated under the influence of heat. The composition of albumen of the white of an egg is stated by Dumas to be: carbon, 54.3; hydrogen, 7.1; nitrogen, 15.8; oxygen, 21.0; sulphur, 1.8;—of the serum, or thin part of the blood of man, 0.05 less of carbon, 0.19 more of hydrogen, 0.07 less of nitrogen, and 0.07 less of oxygen. The sulphur in the white of an egg, uniting with hydrogen, forms sulphuretted hydrogen, which furnishes silver. Albumen is found not only in the egg, but in the blood, in the chyle and lymph, in the interstitial fluid of the muscles, and in the moisture of the serous cavities, as the pericardium and the peritoneum. In the blood, where it is most abundant, it is in the proportion of about 75 parts per thousand; in the lymph and chyle, from 12 to 35 parts per thousand. It is coagulated by a temperature of 160° F., and when in tolerable abundance, as in the serum of the blood, the whole fluid, on boiling, becomes solidified or gelatinous in consistency. The presence of an alkali or an alkaline carbonate, however, in due proportion, will prevent this; and after the albumen is once coagulated, the

coagulum may be redissolved by the action of the alkali. In the blood, the albumen is regarded as its most nutritious ingredient, being employed for the nourishment of the various tissues, by which it is absorbed and afterward converted into materials similar to their own. It is not discharged from the body under its own form with the excretions, except in cases of disease, but is retained and employed for the maintenance of the vital operations.—Albumen is regarded as the representative of a large class of organic substances, as well vegetable as animal, which are known as the albuminoid substances. (See ALIMENT.) They are distinguished by the facts that they all contain nitrogen, in addition to carbon, hydrogen, and oxygen; that all those which are fluid or semi-fluid are coagulable by various means; that they are very ready both to excite and to undergo indirect or catalytic transformations; and that they are all susceptible of putrefaction. They enter very largely into the composition of the food, and constitute its most valuable and nutritious ingredients.—According to recent researches (1865) of Hoppe-Seyler, there is a marked difference between the albumen of eggs and that found in other parts of the animal economy. Vegetable albumen has never yet been prepared in a pure form, and we are unable to say whether it may not constitute a third modification. The two modifications known to chemists at the present time are the soluble and insoluble.

ALBUMINURIA, or Bright's Disease, a disease characterized by the presence of albumen in the urine, a more or less general dropsy both of the cellular tissue and the internal cavities, and an organic change in the substance of the kidneys; so called from the name of its discoverer, Dr. Bright. The acute form of the disease sometimes commences with a chill, followed by more or less fever, with a dry skin, furred tongue, and frequent pulse. In other cases the attention of the patient is attracted by the swollen state of his countenance; the swelling rapidly extends and becomes general; at the same time the urine is greatly diminished in quantity, and is of a dark color, looking as if impregnated with smoke, or red, and evidently containing blood. There is more or less dull pain about the loins, with a dry pallid skin, thirst, disinclination for food, often nausea and vomiting. Sometimes, though happily not often, there is complete suppression of urine. In such cases, as a rule, fatal coma quickly supervenes. In the course of the disease, effusions into the cavities of the pericardium, the pleura, or the peritoneum, with or without inflammation of those membranes, are apt to occur; or epileptic convulsions may come on, often ending in fatal coma. The urine has commonly a specific gravity of from 1.015 to 1.025—not varying much from its ordinary standard; when tested by heat and nitric acid, it shows the presence of albumen, sometimes in such large quantity that the whole of the

fluid is converted into a jelly-like mass. When examined under the microscope, the sediment deposited by the urine, on standing, is found to consist of blood corpuscles, of renal epithelium, and of small fibrinous casts of the uriniferous tubes, containing entangled in them epithelial cells and blood globules. After the disease has continued some weeks in adults, the epithelial casts, as they are termed, sometimes contain a few oil globules; if the patient recover, these gradually disappear as convalescence comes on. On post-mortem examination the kidneys are found to be enlarged, and gorged with blood. Sometimes their exterior is pale, and this paleness extends through the cortical substance, particularly in the cases which follow scarlet fever. Microscopic examination shows many of the convoluted tubes to be crowded with epithelium, especially in those parts of the cortical substance which appear pale to the naked eye.—Of the causes of acute albuminuria, exposure to cold, particularly when the body is exhausted by fatigue, by recent illness, by an innutritious or unsuitable diet, or by excessive indulgence in alcoholic liquors, is undoubtedly the most important. The actions of the skin and of the kidneys are always to some extent vicarious of each other. When there is free perspiration, the quantity of urine is diminished; in cold weather it is increased. In these cases, however, it is only the watery parts of the excretion which are interfered with; and the kidneys continue to free the blood from the excrementitious matters which it is their peculiar function to separate. When disease follows exposure to cold, it is probable that the sudden checking of the function of the skin produces a vascular congestion of the kidneys, an increased pressure of the blood in their vessels, and thus the appearance of albumen in the urine. Other diseases in which the blood is in an altered condition are occasionally attended or followed by albuminuria; thus repeated instances of its occurrence have been met with in connection with acute rheumatism, typhus fever, erysipelas, and purpura. During the desquamative process in scarlet fever, the patient is liable to acute albuminuria. Accurate observers have found that in most cases albumen can, at some time of the later period of the disease, be discovered in the urine. If at this time the patient be incautiously and unduly exposed to the influence of cold, disease of the kidneys attended by dropsy is apt to follow. The attack differs in no respect except its cause from the acute albuminuria which occurs under other circumstances; it has similar symptoms, and post-mortem examination reveals similar appearances. The strumous diathesis predisposes to the disease; cases of scarlet fever in children of that diathesis have always to be watched most carefully, and from the ordinary causes of albuminuria the strumous suffer in large proportion.—It is easy to understand the pathology of the disease. Not only is the urine diminished in quantity, but what is

passed is deficient in urea. The urea which should be eliminated by the urine accumulates in the blood and poisons that fluid. The serum of the blood, of which the albumen is drained off by the kidneys, becomes deficient in that substance, and of lower specific gravity. The pallor of the complexion shows that the blood is deficient in coloring matter; and where the disease has lasted a short time, this is confirmed by direct examination, the blood globules being diminished in proportion. The circulation of a poisoned blood throughout the body causes that liability to secondary diseases which so strikingly characterizes the complaint. While acute albuminuria is always a serious disease, still in a large proportion of cases we can look forward hopefully to the recovery of the patient; yet it must always be borne in mind that at any time secondary disease may be lighted up, which will seriously complicate the case and increase the danger. The existence of the strumous diathesis in a marked degree, or of debility from previous illness, is likewise an exceedingly unfavorable circumstance. The more recent the disease, the better is the prospect of recovery; while the persistent presence of albumen in the urine after a certain time leads us to fear the occurrence of chronic degeneration. The albuminuria following scarlatina generally terminates favorably, and there is no tendency to a return of the disease. When convalescence commences, the urine becomes more copious and pale, and for some time is discharged in large quantity, while the albumen gradually diminishes; but the patient cannot be considered as safe, so long as any trace of albumen can be detected in the urine, or any epithelial casts are discovered under the microscope.—The hygienic treatment of acute albuminuria is sufficiently simple. The patient should be clothed in flannel, and if possible confined to bed; the room should be of a comfortable and equable temperature, and the patient should be most sedulously guarded against exposure to cold currents of air. Throughout the course of the disease, the diet should be unirritating and digestible; any excess in this respect may be attended with bad consequences. When convalescence is established, the preparations of iron will be found exceedingly useful, improving the condition of the blood and the general strength.—*Chronic Albuminuria.* The approach of chronic albuminuria, when not the sequel of an acute attack, is masked and insidious, rarely awaking attention until fatal progress has been made; indeed, persons not suspecting themselves to be ill have in repeated instances died suddenly of what has been supposed to be an apoplectic attack, and post-mortem examination has shown the kidneys and not the brain to be the seat of mischief. In general, however, the symptoms are sufficiently well marked to attract the attention of the observing physician. The patient loses flesh and strength; the appetite fails, or, if good, flatulence and other dyspep-

tic symptoms are present; after a time the color is lost, and the patient has a pallid, sallow, or waxy look; the skin becomes dry; in the morning, on rising, swelling beneath the eyes is noticed, and at night the ankles are œdematous. There is some pain in the back, but it is not commonly so great as to attract attention. If the patient be questioned, it will be found that there is some irritability of the bladder; he has, contrary to his wont, to rise at night to pass urine, although there is no evidence of disease of the bladder itself. The urine is sometimes passed in large quantities, and occasionally the amount is much below the average; it is pale and of low specific gravity, varying commonly from 1.004 to 1.012. Tested by heat and nitric acid for the presence of albumen, this substance is found to vary greatly in amount in different cases, occasionally being present in large quantity, while sometimes only a trace of its existence is discovered; sometimes it disappears altogether, and will only be discovered after repeated examinations. In the course of the disease dropsy of the abdomen is apt to occur, and this often becomes so great as to be the principal source of suffering. Anasarca is also present, and the whole cellular tissue is infiltrated with serum. As in the acute form of the disease, there may be effusion, with or without inflammation, into the cavities of the pericardium and pleura, as well as into that of the peritoneum. A tendency to prolonged somnolence is often observed, and this may lapse into coma, or may alternate with epileptic convulsions. Bronchitis is apt to occur and to prove severe and intractable; pneumonia, too, sometimes comes on insidiously, and may run on rapidly to a fatal issue; and rheumatism, particularly a chronic and unmanageable form of the disease, is not infrequent. It is to the deteriorated condition of the blood that the number, variety, and fatality of the complications of the disease of the kidneys are to be attributed. The principal alteration in that fluid would seem to be chiefly the diminished amount of the blood globules, the hematin, according to Dr. Christison, sometimes reaching only one third of its natural quantity, and the presence of the retained urea.—The duration of the disease varies very greatly in different cases. Among the laboring classes whose avocations lead them to exposure to the inclemencies of the weather, and in whom sickness brings too often privation of comforts and mental depression, death commonly occurs after no very protracted period; but among those whose position enables them to avoid fatigue and exposure, and who are more on their guard against the first invasion of disease, chronic albuminuria often lasts for years, leaving its victims a very fair measure of the enjoyments and labors of life; their situation, however, is always precarious, and serious or fatal disease may at any moment be brought on by apparently trivial circumstances.—Intemperance in eating and

drinking, but especially in the use of fermented and distilled liquors, is the great cause of chronic albuminuria, in cases where it is not consequent upon the acute disease. One form of the disease is so commonly associated with the gouty diathesis, that it has been named by Dr. Todd the gouty kidney; but the same form of disease is often found in those who have never known gout. It occurs most frequently in those of strumous habits, and, at least in hospital cases, it is no uncommon attendant upon consumption. Exposure to cold and wet, fatigue, want, and mental anxiety, may all be put down as occasional causes; yet many cases occur in which we are unable to trace the origin of the complaint.—In the so-called granular degeneration of the kidney, the organs in advanced stages of the disease are very much contracted, so as not to be more than one third or one fourth of their natural size. They have a granular appearance; the capsule is denser and whiter than natural, and is peeled off with difficulty. On cutting open the kidney, the wasting is found to have taken place mainly at the expense of the cortical substance, which is contracted and atrophied, and presents the same granular appearance which is observed upon the surface. In the waxy kidney the organ is enlarged sometimes to twice its natural size. It is of a pale buff color, and presents when cut no trace of granulations; on examination under the microscope the tissue of the organ is found to be filled with an unorganized fibrinous exudation, and the tubes contain a similar deposit, in the form of waxy casts identical with those which microscopic examination detects in the urine. The fatty kidney is enlarged, the surface of the organ is smooth and pale, or more commonly mottled by red vascular patches, and its texture feels softer than natural. On microscopic examination the convoluted tubes are found filled with oil globules.—In chronic albuminuria, where neither dropsy nor other formidable complication demands attention, the treatment consists rather in hygienic measures, in a careful direction of the patient's clothing, diet, and exercise, than in active medication. Flannel should always be worn next the skin, and exposure to wet and cold carefully shunned; all inordinate exercise, whether of mind or body, and all excess of every kind, should be forbidden; the diet should be nutritious, but moderation and regularity must be insisted on; all fermented liquors should be avoided, though, where long habit has rendered their use necessary, the patient may be left to choose the article which best agrees with him.

ALBUQUERQUE, a town and fortress of Spain, in the province and 25 m. N. of Badajoz, and 9 m. from the Portuguese frontier; pop. 7,500. It is the seat of the dukes of Albuquerque, and has a large trade in wool.

ALBUQUERQUE (Port. *Albuquerque*), **Affonso d'**, called the Great, and also the Portuguese Mars, one of the first Portuguese conquerors

and second viceroy of India, born near Alhandra, in the province of Estremadura, in 1453, died at sea, in the bay of Goa, Dec. 16, 1515. He was brought up at the court of Alfonso V., where his father Gonçalo occupied a distinguished position, and was afterward grand equerry of Kings John II. and Emanuel. He had already seen considerable military service, and distinguished himself both by land and sea, when in 1503 he sailed with his cousin Francisco, in command of a small fleet, to India, by the newly discovered Cape of Good Hope passage. Having rendered important services to the king of Cochin, on the S. W. coast of India, the adventurers gained permission to form a settlement in his dominions, which was the commencement of the Portuguese power in the East. Albuquerque next (1506) accompanied Tristan da Cunha on an expedition to the E. coast of Africa. They carried on a successful warfare for some time against the Arabs and other inhabitants of that coast, until Albuquerque, being left in command of a portion of the fleet by Da Cunha, determined on an attempt against the island of Ormuz, the great entrepot of the commerce between Persia and India. He was at first successful (Sept. 25, 1507), but the Persian commander, rallying his forces, repulsed him and drove him back to his ships. He was now joined by three more vessels, and sailed for India, having received a secret commission to supersede the Portuguese governor, Dom Francisco d'Almeida; but the latter refused to recognize him, and threw him into prison. On the arrival of the grand marshal of Portugal with a large fleet, he was released and installed as governor and commander-in-chief. In an attempt against Calicut the grand marshal was killed and Albuquerque wounded and forced to retreat. He now made his way to Goa, which he seized in the absence of Idal Khan, the ruling Arab prince, on an expedition into the Deccan (Feb. 17, 1510); but his force was too small to retain his conquest, and Idal Khan, having gathered an army, drove him out of the town, and forced him to retire to his ships, which were unable to cross the bar in the face of the monsoon till Aug. 15. In November he returned, stormed the city, and permanently established himself there. The next year, Diego de Vasconcellos having been ordered to lead an expedition against Malacca, Albuquerque seized and sent him back to Portugal, took command of the expedition himself, captured the town with a force of 1,000 against 30,000 natives and 3,000 cannon, and plundered it of an enormous booty. After remaining a year at Malacca, and establishing Portuguese power there, he sailed for Goa, and was shipwrecked on his voyage; but he escaped with life, and on reaching the city repulsed an attempt to recover the place made by Idal Khan. His success struck such terror into the natives, that they submitted and left the Portuguese in peaceable enjoyment of their acquisitions. In pur-

suance of peremptory orders from home, he now (1513) led an expedition to the Red sea for the purpose of breaking up the commerce between India and Egypt, in order that the Indian trade might be monopolized by Portugal. Repulsed in an attack upon Aden, he returned to Ormuz in 1515, and secured it without a blow, Portugal retaining possession until 1622, when Shah Abbas recovered it. Many attempts had been made by intriguers at home, jealous of his fame, to injure him, and more than one commander had been sent out to supersede him; but he disregarded the orders of the court. He was, however, at length recalled (1515), and his health having suffered in the climate of the Red sea and Persian gulf, his vexation at his disgrace so operated on his enfeebled frame that he sank under it, and died in his 63d year. He was buried at Goa. His loss was deplored as a national calamity, and the king endeavored to atone for his previous ingratitude by honor to his memory after his death. In his personal habits he was moderate, and such was his reputation for justice, that half a century afterward both Mohammedans and Hindoos visited his tomb to pray for his protection against the extortions and oppressions of his successors. The celebrated *Commentarios do grande Affonso d'Albuquerque* was edited from his papers by his natural son Affonso, minister of finance under John III. Of the original edition there are only three copies extant, one of which is in the royal library of Portugal. The best edition was executed at the royal printing office, Lisbon, in 1774 (4 vols. 8vo).

ALBURNUM, that part of the stem of trees which timber merchants call sap wood, in contradistinction to heart wood. It is the newly formed wood, lying next below the bark, and is a delicate fibrous tissue, the principal use of which is to convey the crude sap from the roots to the leaves. It is, therefore, a necessary part of all exogenous trees. But it is of a very perishable nature, and only loses that quality when, being enveloped within exterior layers of the same substance, it becomes combined with other secretions, which solidify it and convert it into duramen, or heart wood. Most plants, and all trees valuable as timber, have the sap wood and heart wood distinct, the one forming the external layer, the other the core. Some, however, consist of alburnum only, and are known as whitewood, which are useless, or of use only for the most temporary purposes.

ALCEUS, a Greek lyric poet and warrior, a native of Mitylene in the island of Lesbos, flourished toward the close of the 7th century B. C. He served in the war which took place in 606 between the Athenians and Mitylenians for the possession of Sigeum, on the coast of Troas. He was a partisan of the nobles in their feuds with the people of Mitylene, and shared the exile of his faction, after a futile attempt to re-establish himself in his country by force of arms. His poems, originally consisting of ten

books, are said to have exhibited the Æolian lyric in its highest perfection, but only fragments have come down to us. Some were warlike or patriotic; some bacchanalian or erotic songs; while others were hymns, or epigrams, or poems addressed to individual friends. He is considered the inventor of the Alcaic metres. Horace admired and imitated him. The best collection of the extant fragments of Alceus will be found in Bergk's *Poete Lyrici Græci* (Leipsic, 2d edition, 1853).—There were two other Greek poets of the same name, of Athens and Messene, and of the 3d and 4th centuries B. C., of whose writings some fragments also remain; but they are of little importance.

ALCAIDE, an executive officer among the Spaniards, Portuguese, and Moors, appointed to take charge of a castle or fort, or to superintend a prison. (See **ALCALDE**.)

ALCALÁ, the name of several towns in Spain, derived from the Moorish *El Khalaat*, the castle. **I. Alcalá de Henares** (anc. *Complutum*), a town on the river Henares, in New Castile, 17 m. E. N. E. of Madrid; pop. about 9,000. It is celebrated for its university, instituted by Cardinal Ximenes in 1510, which was long a famous school of law and divinity, but in 1836 was suppressed, and the library removed to Madrid. The Complutensian polyglot Bible was issued from it at the expense of its illustrious founder. (See **POLYGLOT**.) It has a military school, a magnificent church, a number of convents, and a palace of the archbishop of Toledo. Alcalá was the birthplace of Cervantes, the historian Antonio Solis, the naturalist Bustamante de la Camera, the emperor Ferdinand I., and many other famous men. It was in possession of the Moors until the 12th century, when it was recovered by Don Bernardo, archbishop of Toledo. **II. Alcalá la Real**, a small town of Andalusia, 27 m. S. S. W. of Jaen, on a plateau 2,804 feet above the sea; pop. about 7,000. It was the scene of a victory by Sebastiani over the Spaniards in January, 1810, which resulted in the capture of Granada by the French.

ALCALDE, in Spanish, the title of a civil dignitary, either judicial or administrative, with which *aleaide* is sometimes confounded. (See **ALCAIDE**.) Both terms are probably derived from the Arabic *al-cadi*. The *alcalde mayor* is a local judge who presides over the tribunals, and is distinct from the municipal *alcalde* or *corregidor*, who is not a lawyer. The *alcalde pedáneo* is a justice of the peace, and is elected by the people. *Alcaldes de casa y corte* form a bench of judges for the trial of criminal or civil causes within certain circuits, to whom an appeal lies against the decision of any individual of their number.

ALCAMENES, a Greek sculptor, flourished in the latter half of the 5th century B. C. He was the most famous pupil of Phidias, and is said to have unsuccessfully competed with him in a statue of Minerva. His masterpiece was a statue of Venus, now lost.

ALCAMO, a city of Sicily, in the province of Trapani, 23 m. S. W. of Palermo; pop. in 1872, 20,890. It was originally a Saracenic town, built on the summit of a neighboring hill. The Saracens were expelled in 1223, and the town was rebuilt at the foot of the hill. It is surrounded by a battlemented wall of the 14th century, but the place is very poor and decayed. In the vicinity are the ruins of ancient Segesta and quarries of yellow marble.

ALCÁNTARA (Arab., the bridge; anc. *Norba Casarea*). **I.** A small town in Spanish Estremadura, near the Portuguese frontier, on the left bank of the Tagus, in the province and 34 m. W. N. W. of Cáceres; pop. about 4,500. A magnificent six-arch bridge, built across the Tagus in the reign of Trajan, was blown up by the British during the Peninsular war. **II.** **Knights of**, a Spanish order deriving their origin from the knights of San Julian de Peyrero, a small body of valiant Christians in the 12th century who vowed continual war against the Moors. In 1215 Alcántara, which had been in possession of the Moors, was recovered by Alfonso IX., and the grand master of Calatrava being unable to undertake its defence, the duty was assigned to the brothers of San Julian, who changed their name to that of knights of Alcántara. In 1495, the grand master dying, Ferdinand the Catholic became administrator of the order, and united the office of grand master with the crown. The order as an organized body has since been abolished, and exists now only as a military order of merit. In addition to the usual vows of the monk-soldier, the knight of Alcántara was bound to maintain the immaculate conception of the Virgin. After 1540 a change was made in the statutes of the order, which permitted the knights to marry.

ALCAVALA, or *Alcabala*, a duty imposed in Spain and its colonies on all transfers of property. It was originally laid in 1341 as an ad valorem tax of 10 per cent., and was afterward increased to 14 per cent. It was even levied on such movable chattels as manufactured commodities, and was attached to all wholesale transactions. This oppressive impediment to the operations of trade continued over the greater part of the Spanish realm until swept away by Napoleon in 1808. Catalonia and Aragon purchased from Philip V. an exemption from the alcavala by the substitution of a tax on rents and on incomes.

ALCAZAR (Arab., the royal castle). **I.** In Spanish, the general name for a castle or citadel—applied to the castles at Seville and Segovia, and to many others. **II.** **Alcazar de San Juan**, a town of Spain, in New Castile, in the province and 48 m. N. E. of Ciudad Real; pop. about 8,000. It has manufactures of saltpetre, soap, chocolate, &c., and is also a railway centre, where the line from Valencia joins that from Madrid to Córdoba. Near it are rich iron pits.

ALCESTIS. See **ADMETUS.**

ALCHEMY (Arab. *al-kimia*, from *al*, the, and Gr. *χημεία*, chemistry), the ancient name for the science of chemistry. It is sometimes called the hermetic art, from Hermes Trismegistus, anciently reputed its discoverer. The word alchemy is first found in the works of the Greek author Zosimus of Pannopolis, who wrote in the early part of the 5th century. During the middle ages it was a mysterious art, aiming to change inferior metals into silver and gold, and to find the so-called elixir of life, which was to be the universal remedy for all possible diseases, rejuvenating the old, and even preventing death. From the 10th to the 17th century there was no distinction made between the words chymia or chemistry and alchemy; but since the latter period, this class of researches becoming more positive and scientific, it has been agreed to confine the use of the word chemistry to the positive modern knowledge, and to designate by the term alchemy that imaginary science which sought impossible results from misunderstood or misapplied principles. For this reason the name alchemist has become an expression of contempt. Still the ancient alchemists, who called the subject of their investigation the divine art, were the precursors of our modern science, and enriched posterity with the knowledge of many valuable facts, which laid the foundation of chemistry. The first authentic account of alchemy is found in Suidas, a Byzantine author of the 10th or 11th century, who mentions that the emperor Diocletian, after the conquest of the rebellious Egyptians in the year 296, ordered that all the writings on the chemistry of gold and silver should be burned, in order that the people should not grow too rich by making gold and again commence a rebellion. It appears further that the Greeks living in Egypt in the 5th century were industrious laborers in this field, as a great number of genuine manuscripts on alchemy, dating from the 5th and 6th centuries, are now found in many of the large libraries in Europe, nearly all coming from Alexandria. The Arabs learned this art, after their great invasion of northern Africa and southern Europe, from some of the peoples they conquered. The greatest Arabian author on alchemy, Jaffar or Geber, who lived toward the end of the 8th century in Seville, was enlightened enough not to suppose that any alchemist had ever succeeded in making gold. However, it appears that he did not doubt the possibility of the transmutation of metals, as he believed that all metals were compounds of three elements. With all their errors, however, some of the ancient Arabian authors give very striking definitions of alchemy, such as the science of the balance, the science of weight, the science of combustion. Jaffar, or Geber, marked an epoch in chemical science equal to that of Lavoisier exactly 1,000 years later. In his time no stronger acid was known than concentrated vinegar, and he discovered and described nitric acid and aqua regia, and also

discovered that a metal when oxidized (or, as he called it, calcined) increases in weight; a fact rediscovered 1,000 years later by Europeans, and then brought to bear in the destruction of the absurd phlogiston hypothesis then prevailing. He describes the absorption and evolution of gases by and from liquids and solids, and gives singularly clear instructions in regard to filtration, distillation, sublimation, water and sand baths, cupels of bone earth, and various other chemical operations. He made nitric acid by distilling a mixture of blue vitriol, alum, and saltpetre, and aqua regia by adding sal ammoniac to nitric acid; he could then obtain gold in solution, and so solved the great problem to which before his time all the efforts of alchemists had been vainly directed, the manufacture of gold in a potable state. No wonder that Roger Bacon speaks of him as the *magister magisterium*. Rhazes, head physician to the hospital of Bagdad, invented about a century later the preparation of sulphuric acid by the distillation of green vitriol, as Nordhausen vitriol is now prepared. He was also the first to make absolute alcohol by distilling spirits over quicklime. Achild Bechil distilled a mixture of urine, clay, lime, and charcoal, and obtained what he called an artificial carbuncle, as it shone in the dark like the moon; it was phosphorus, rediscovered by Brand in Hamburg in 1669. The taste for this class of pursuits diffused itself over Europe by two channels, the scientific Italians, Germans, Englishmen, and Frenchmen who visited Spain frequently, and the Greeks who fled from the Mussulman invasion. Already in the 10th century we find traces of alchemy in different European countries; but it was most ardently pursued in the 15th, 16th, and 17th centuries, in the course of which many deceptive and imaginary sciences became associated with it, such as theosophy, cabala, chiromancy, necromancy, astrology, and magic. Besides the great number of those honest alchemists who deceived the credulous masses by their own confidence expressed in mysterious and sanguine writings, there was a class of impostors who travelled about extorting money from the credulous. Edward III. of England paid large amounts of money to the celebrated alchemist Raymond Lully, and Henry VI. in 1440 gave several patents for the making of gold. Rudolph II. of Germany founded in Prague a regular alchemistic university. Augustus I. of Saxony himself worked, with his wife Anna as assistant, in the pursuit of gold-making, and kept besides two alchemists on a regular salary. Duke Frederick of Würtemberg, who died in 1608, wasted all the revenue of his land in experiments. Christian IV. of Denmark appointed Harbach, the director of the mint in Copenhagen, as his private alchemist. The emperor Ferdinand III., Duke John Philip of Mentz, and a great many others could be enumerated; and it is strange that notwithstanding numerous glaring deceptions, and revelations of the most contemptible dishonesty, which were often pun-

ished by public executions, the belief in the possibility of making gold maintained itself. When Böttger escaped from Berlin in 1703, he was placed in prison in Dresden by the elector of Saxony, to compel him to make gold; he succeeded, however, in discovering there the much more valuable art of making porcelain. Even the celebrated astronomer Tycho Brahe occupied himself with attempts to make gold, but with the purpose of obtaining means to prosecute his astronomical investigations on a larger scale. Until the end of the 17th century all chemical labors were chiefly directed to the same end, though many practised this art for medical purposes. Among the many authors on alchemy must be mentioned Albertus Magnus, Roger Bacon, Arnold de Villanova, Raymond Lully, Basilius Valentinus, Theophrastus Paracelsus, Libavius, Becher, Kunckel, and Glauber.—During the 18th century it is difficult to distinguish between an alchemist and a true chemist, as many really scientific men were kept in error by believing Jaffar's false theory that all metals were compound bodies. Even as late as 1772, Schröder, professor in Marburg, and Wenzel, a distinguished chemist in Freiberg, defended the theory of the transmutation of metals. Guyton de Morveau firmly believed that silver could be changed into gold simply by melting with it sulphuret of antimony and arsenic; but it was afterward discovered that all the gold thus obtained could be accounted for as being present beforehand in the materials used. In 1796 two German physicians in Westphalia founded a society for the purpose of investigating the transmutation of metals; many branch societies were formed, which were flourishing in 1804, and still in existence in 1820. In a text book of chemistry (Baudrimont, *Traité de chimie*) published so lately as 1844, it is stated that a certain "Mr. Javary has obtained very surprising results by following the prescriptions of the ancient alchemists, so that there is hope of at last seeing the great work succeed." In a still later publication (1856) Fifereau affirms that the metals are compound bodies, and that silver can be changed into gold.—The alchemists' articles of faith were as follows: "1. There exists a preparation, solid in form and red of color, called the philosopher's stone, the grand elixir (*major magisterium*), the red tincture, which, when it is placed in very small doses on melted liquid silver, mercury, lead, or some other common metal, causes a transmutation of the same into gold. 2. The same preparation, used in very small doses as a medicine, cures all diseases, rejuvenates the old, and prolongs life; wherefore it is called the panacea of life, and since it contains the essence of gold, *aurum potabile*. 3. There is another preparation of a white color, called the stone of the second degree, the little elixir (*minor magisterium*), the white tincture, which is equal to the first in half a degree of perfection, and changes the common metals into silver."

ALCIATI, Giovanni Paolo, a theologian, born in Piedmont, died in Dantzic about 1570. He embraced Protestantism, and figured in Geneva, but soon afterward promulgated doctrines about the Trinity which were as distasteful to the Protestants as to the Catholics. He and his fellow laborers, among whom was a physician named Blandrata (see **BLANDRATA**), had to flee from Geneva, and chose Poland for a refuge, where they met a hearty reception. He wrote two letters (1564 and 1565) to Gregorio Pauli, maintaining that our Saviour did not exist before his birth of the Virgin Mary.

ALCIBIADES, an Athenian statesman and general, son of Clinias and Dinomache, born in Athens in 450 B. C., died in Bithynia in 404. He boasted his descent from the Telamonian Ajax, and through him from Jupiter himself. His grandfather had been among those who attempted the banishment of the Pisistratidæ, and had received the prize of valor at the battle of Artemisium; and his father fell in the battle of Charonea (497). Alcibiades was educated in the house of Pericles, his maternal relative, and from a child excelled in all studies and in all physical exercises. As he advanced to manhood, his birth, person, abilities, and wealth, joined to the consideration in which he was held by Pericles, procured for him a crowd of friends and flatterers; and he became as distinguished for the audacity of his dissipations as for the brilliancy of his station and abilities. Socrates, who appreciated his capacities, gained great influence over him, and from this time his whole life seemed a wavering between virtue and vice. He gave the first proofs of his valor in the battle of Potidæa (432), where he was wounded while fighting side by side with Socrates, whose protection alone saved his life. He returned this service to his teacher in the battle of Delium (424), where his efforts saved Socrates from the sword of the conquering Bœotians. He always carried in war a shield inlaid with gold and ivory, and bearing the device of Jupiter hurling a thunderbolt. He distinguished himself in the public festivals of the Greeks, and at the Olympic games he was not content with furnishing one chariot, like the other wealthy young men, but equipped and sent seven, with which he bore off the first three prizes. He took little part in public affairs till the death of the demagogue Cleon, in 422, when he became the head of the new war party in opposition to Nicias. Nicias had just concluded a peace of 50 years between the Athenians and Lacedæmonians, and Alcibiades, jealous of the power of Nicias, set himself to break the peace and to form a union of the Greek states against Sparta. His counsels caused the great expedition to Sicily (415), of which he was appointed commander together with Nicias and Lamachus, and which he thought would be a step toward the conquest of Magna Græcia, Carthage, and Peloponnesus. While the preparations for this expedition were going on, all the

busts of Hermes in Athens were during one night mysteriously mutilated. The cause and the authors of this sacrilege were unknown, but the popular fears connected it in some unaccountable way with an attempt to overthrow the Athenian constitution. That Alcibiades had anything to do with the offence there was no evidence, and if he was guilty of it, it was probably one of the unpremeditated results of a nocturnal debauch. Nevertheless, suspicion was thrown upon him, and immediately produced great popular indignation. The Sicilian fleet being nearly ready to sail under his command, he demanded an investigation before his departure from Athens. This his enemies refused to give him, thinking to increase the popular odium against him in his absence. The expedition had hardly reached Sicily when the anger of the people became so excessive that his ruin was fully determined upon. But as he had already gained shining advantages in Sicily, and had become the favorite of the soldiers, it was deemed hazardous to pass public sentence upon him while he was at the head of an army. He was therefore recalled. On his voyage homeward he escaped at Thurii and fled, first to Argos, and then to Sparta. Meantime sentence of death was passed upon him at Athens, and his property was confiscated. In Sparta he adapted himself skilfully to the severe manners of the country, became a favorite of the populace, and, being now the avowed enemy of his own country, he persuaded the Lacedæmonians to send help to Sicily against the Athenians. He then effected an alliance between the Spartans and the king of Persia, for the purpose of supporting the Chians in revolt against Athens. He passed over into Asia Minor, and roused all Ionia into rebellion. Soon, however, his successes and great influence excited the jealousy of the principal Spartans, and Alcibiades took refuge with Tissaphernes, a Persian satrap. He who had won the admiration of the Spartans by adopting all their simplicity, and practising all their austerity, now merited the applause of the orientals by vying with them in Asiatic luxury. An exile both from Athens and Sparta, he began now to look with longing toward his native country. He persuaded Tissaphernes to desert the cause of the Spartans, and to show willingness even to assist the Athenians, for which service he was recalled from banishment in 411. Though he did not return immediately to Athens, he yet used his influence to make the government aristocratical, and received command of the Athenian fleet at Samos, with the determination not to see again his native land till he had rendered services commensurate with the evils which he had caused it. Defeating the Lacedæmonians both by land and sea, he was suddenly arrested by Tissaphernes, who wished to avoid suspicion of having authorized the enterprise. But finding means to escape, Alcibiades again put himself at the head of the army, defeated the Lacedæ-

monians and Persians at Cyzicus, captured that town, Chalcedon, and Byzantium, restored to the Athenians their supremacy by sea, and after these brilliant achievements returned to Athens in 407, where he was received with general enthusiasm. His triumph was complete when he celebrated with unusual splendor the Eleusinian mysteries. Being appointed commander-in-chief of all the land and sea forces, he sailed with a fleet to Asia Minor, to reduce some of the Ionian islands and cities. The pay and provisions for his soldiers not arriving, and his position becoming dangerous, he was obliged to leave his army in command of Antiochus, while he himself sought supplies in Caria. During his absence, the Spartan commander Lysander had the art to draw Antiochus into an engagement, in which the Athenians were defeated and a part of their vessels destroyed. Alcibiades now again lost favor. He went into voluntary banishment, to a castle which he had built in Pactye, Thrace. When the Athenian fleet was in 405 lying at Egospotamos, Alcibiades informed the generals of the perilous position which they had selected, and forewarned them of the fatal result of the battle soon after fought there, which caused the fall of Athens in the following year, and its subjection to the thirty tyrants. The Spartans, who now ruled at Athens, renewed the decree of banishment against him, and Alcibiades fled toward the court of Artaxerxes II, to win over that monarch to the cause of his fallen country. He was on his way thither, in the dominions of the satrap Pharnabazus, when one night his house was surrounded by armed men, and set on fire. He rushed out, sword in hand, but fell pierced with arrows. The Spartans, feeling their supremacy insecure while Alcibiades lived, had probably thus plotted with Pharnabazus for his destruction.

ALCHINDUS. See ALKINDI.

ALCINOUS, in Greek mythology, son of Nausithous and grandson of Neptune. In the story of the Argonauts he is king of the island of Drepane, where he entertained Jason and his companions. In the *Odyssey* he rules over the Phæacians in the island of Scheria.

ALCIPHILON, a Greek writer, supposed to have been a contemporary of Lucian, flourishing about A. D. 170. He was the author of 113 fictitious letters, in which certain representative characters—fishermen, peasants, parasites, and courtesans—are made to portray, in the purest Attic, the opinions and idiosyncrasies of the classes to which they respectively belong. These letters are mostly given as if written from Athens or its vicinity, in the age immediately following that of Alexander the Great. The best edition of them is that of Seiler (Leipsic, 2d ed., 1856).

ALCIRA, an old walled town of Spain, on an island in the river Jucar, in the province and 24 m. S. of Valencia; pop. about 14,000. It is irregularly built, but is adorned by several churches and bridges over the Jucar, and a fine

railway depot belonging to the Valencia and Almansa line. It was an important town in Moorish times.

ALCMÆON. I. In ancient Greek legends, a son of Amphiarus and Eriphyle of Argos, and brother of Amphilochus. Eriphyle having been bribed by Polynices with the necklace and robe of Harmonia to induce Amphiarus to join the expedition of the seven against Thebes, the latter, foreseeing that he should fall, charged his sons to kill her when they were grown up. Meantime, an oracle having declared that the expedition of the epigoni would be successful if commanded by Alcmæon, Polynices again bribed Eriphyle with the peplus of Harmonia to persuade him to comply. On his return Alcmæon fulfilled his father's injunction by killing her. For this crime he was afflicted with madness and tormented by the Furies, who drove him into exile, and doomed him to a life of perpetual wandering. Arriving in Psophis, he was hospitably received and purified by its king, Phegeus, who gave him his daughter Arsinoë in marriage. To her Alcmæon presented the necklace and robe of Harmonia. But Psophis having been visited by a famine because of Alcmæon's sojourn there, he had to depart, and, by the advice of an oracle, went to the land of the river god Achelous, where he married the nymph Calirrhœ. His new spouse coveting the magical robe and necklace which he had given to Arsinoë, Alcmæon went to Psophis and obtained them from the daughter of Phegeus, under the pretence that he was going to dedicate them at Delphi. But when Phegeus heard that they had been presented to Calirrhœ, he sent his sons to slay Alcmæon and avenge the insult offered to their sister. Alcmæon was afterward worshipped as a hero in many parts of Greece. II. A Greek natural philosopher, born in the Hellenic city of Crotona in southern Italy, about the middle of the 6th century B. C. He is said to have studied under Pythagoras, and to have been the first who ventured on the practice of dissecting animals. He wrote several medical and philosophical treatises, of which a few fragments remain.

ALCMÆONIDÆ, a noble Athenian family, descendants of Alcmæon, the great-grandson of Nestor. The whole family were expelled from Athens about 596 B. C. by a council of 300 nobles, to whom, by the advice of Solon, they had submitted the case of the archon Megacles, one of their number. Megacles was accused of having been guilty of sacrilege in his treachery toward Cylon and his comrades, whom he killed after promising them safety—a crime which in the opinion of the council brought a stain upon all the Alcmæonids. After an exile of about 30 years they succeeded in returning to the city, and even, after a few years, in seizing the government and expelling Pisistratus. Although Megacles afterward restored him, and gave him his daugh-

ter in marriage, new quarrels broke out, and Pisistratus was again banished. Collecting an army, he defeated and again expelled the Alcmaeonids. During this period of renewed exile, the family magnificently restored the temple of Apollo at Delphi, which had been burned. Aided by the popularity given them by this great work, and by the friendship of the Spartans, they were in 510 restored for the second time to Athens, where many members of the family became illustrious. Among these were Clisthenes, Pericles, and Alcibiades.

ALCMAN, or **Alcmaeon**, a Spartan lyric poet, flourished about 650 B. C. He is said to have been by birth a Lydian, and originally a slave, and to have died at a very advanced age. He wrote chiefly in Spartan Doric. His poems, of which some fine fragments are extant, were mostly erotic.

ALCMEÑA, in Greek mythology, a daughter of Electryon, king of Mycenæ. She had ten brothers, who, save one, were slain by the sons of Pterelans. Alcmena had been betrothed to Amphitryon, but she nevertheless declared that the man who avenged the death of her brothers should be her husband. Amphitryon, in order to prove himself worthy of her hand, undertook the enterprise. During his absence, Jupiter visited Alcmena, and by assuming the likeness of Amphitryon, and pretending to have avenged the death of her brothers, obtained her favor. She thus became the mother of Hercules, almost at the same time that she bore Iphicles to Amphitryon. After her death, Jupiter sent Mercury to transport her body to the Elysian isles.

ALCOCK, **Sir Rutherford**, a British diplomatist, born in London in 1809. He was a surgeon in the navy in Portugal in 1833-'4, inspector of hospitals under Sir de Laey Evans in Spain, in 1835-'7, and auditor of accounts of the English-Spanish legion in 1839-'44. He was afterward consul successively at Foo-Chow, Shanghai, and Canton, China. In 1859 he held the joint offices of consul general and minister in Japan. As a result of his energy in resenting Japanese outrages upon Europeans, attempts were made upon his life in 1860 and 1862. On his return to England he published "The Capital of the Tycoon, or Narrative of Three Years' Residence in Japan" (2 vols., London, 1863). He was made K. C. B. in 1863. From 1865 to 1871 he was envoy extraordinary and minister plenipotentiary and chief superintendent of British commerce in China. He is also the author of "Medical History of the British Legion in Spain" (1838), "Life's Problems" (2d ed., 1862), and other works.

ALCOHOL, in popular language, the intoxicating principle of fermented liquors. The word is of Arabic origin, and means "to paint," probably in reference to the use of this compound to dissolve pigments which are insoluble in water. Chemists understand by alcohol the hydrate of a hydrocarbon radical, and include

a numerous class of bodies under this designation. Ordinary vinic alcohol is formed in the decomposition of glucose (grape sugar) by fermentation. One part of grape sugar, represented by the formula $C_6H_{12}O_6$, is split up by a ferment into two parts of alcohol and two parts of carbonic acid: $2(C_2H_5O) + 2CO_2$. Hennel so long ago as 1828 (see "Philosophical Transactions") says: "By combining olefiant gas with sulphuric acid, we may form sulpho-vinic acid, from which we may obtain at pleasure, by varying the circumstances of decomposition, either alcohol or ether." This observation has since been confirmed by M. Berthelot, who has succeeded in making alcohol synthetically, by combining water with olefiant gas: $C_2H_4 + H_2O = C_2H_5O$. Alcohol for commercial purposes is obtained by distilling wine and other liquors that have undergone vinous fermentation; carbonate of soda is sometimes added to keep back acetic acid, and fusel oil is removed by charcoal. The alcohol of the London Pharmacopœia contains about 82 per cent. of alcohol and 18 of water. Its specific gravity is required to be 0.838, water being 1.000. It is thus seen that the less water it contains, the less is its specific gravity; and this property is therefore a convenient test of its purity. In consequence, however, of condensation of the two fluids when mixed, this test cannot be applied except in connection with tables of reference prepared for this purpose.—To prepare absolute or anhydrous alcohol, some substance must be placed in it which shall retain the water. Fused carbonate of potash is such a substance. It absorbs the water, and the alcohol nearly anhydrous occupies the upper part of the vessel, whence it is distilled off nearly pure. Its specific gravity is now reduced to 0.815, and its percentage of water to about 5. Quicklime, well powdered, and thoroughly mixed and shaken with the alcohol, is sometimes used instead of the carbonate of potash; but chloride of calcium is said by some to be more effective than either. The salt is first fused to free it from water, and is then mixed with an equal weight of the spirit in a well stoppered bottle. When the solution is effected, it is poured into a retort or still, and distilled at a moderate heat. The product of the first half is absolute alcohol. Its specific gravity at a temperature of 60° is 0.794.—Rectified spirit may be deprived of a portion of water merely by being left in a bladder, or in a wide-mouthed bottle tied over with bladder, and kept at a temperature of 105° to 120°. By the principle of exosmosis, the water evaporates in part through the membrane. Alcohol has thus been brought from sp. gr. 0.867 to 0.817. Pure alcohol is a colorless fluid, of an agreeable odor and strong pungent taste. It has a great affinity for water, absorbing it from the atmosphere, and increasing in specific gravity with the amount it receives. Mixed with water, heat is at first evolved, showing that a chemical union has

taken place; another evidence of which is the condensation and diminution of bulk, and a less specific gravity. The greatest heat and condensation result from a mixture of 52.3 per cent. of alcohol and 47.7 of water, the volume after condensation being equal to 96.35. The specific gravity, therefore, of such mixtures can only be determined by experiment.—Diluted with water, alcohol acts as a stimulant, exciting particularly the nervous and vascular systems. In large doses it produces intoxication, and when taken pure acts as a narcotic poison, producing death. It is very inflammable, burning with a pale bluish flame without smoke. The products of its combustion are carbonic acid and water. Absolute alcohol boils at 173° F. The specific gravity of its vapor is 1.6133. Under the exhausted receiver of an air pump it boils at common temperatures. No degree of cold ever yet obtained has effected its congelation. Faraday exposed it to a temperature of 166° F. below zero, which caused it to thicken considerably. It is thus well suited for thermometers for measuring low temperatures.—Alcohol is employed in medicine as a solvent in the preparation of tinctures. It is also a solvent of resins, gums, &c. With the former it makes varnishes; with essential oil, perfumed spirits. The ethers are preparations of it in combination with an acid. It is used with spirits of turpentine to make camphene and the various other illuminating fluids of this class. It is used to preserve anatomical preparations, its effect being to combine with the moisture, and so prevent this from acting upon the animal substance to produce decay. To the chemist it is valuable as a convenient fuel, producing in his lamp much heat with no annoyance from smoke; and it is of frequent use as a reagent for separating salts, one of which is soluble and the other insoluble in it.—The quantity of alcohol in wine, beer, and other fermented liquors, is very variable. Prof. Brande found from 1 to 2 per cent. only in small beer; 4 in porter; from 6 to 9 in ales; about 12 in the light wines of France and Germany; from 19 to 25 in port, sherry, and other strong wines; and from 40 to 50 per cent., and occasionally more, in brandy, gin, and whiskey. The strength of these liquors is ascertained by various expedients; but the process is sometimes complicated by reason of the different ingredients intermixed to color, sweeten, or flavor the liquor, or fraudulently added to alter the specific gravity, or to substitute a cheaper material. Mixtures thus complicated require to be first distilled, before their strength can be ascertained by the usual process of specific gravity. Common modes of judging of the strength are by tasting, observing the size and appearance of the bubbles when shaken, the sinking or floating of olive oil in them, and the appearances they exhibit when burned. If cotton or gunpowder immersed in them is inflamed by their combustion, the spirit is considered pure.—Alcohol is decomposed by passing through a red-hot glass or porcelain tube,

into carbonic acid, water, hydrogen, olefiant gas, marsh gas, naphthaline, empyreumatic oil, and chareoal. By electrolysis, on adding potash, hydrogen is given off at the negative pole and aldehyde resin is formed at the positive pole. The product of its combustion in the air is carbonic acid and water. The vapor of alcohol mixed with air explodes by contact with flame or an electric spark. On contact with platinum black it is imperfectly oxidized, forming carbonic acid, water, aldehyde, acetic acid, formic acid, acetal, and a peculiar compound with an excessively pungent odor. Chlorine gas converts alcohol into aldehyde, chloral, chloride of ethyl, and acetate of ethyl. One of these products, chloral, has recently been introduced as a valuable hypnotic medicine. Concentrated chloric acid ignites alcohol; dilute, forms acetic acid. Alcohol unites in definite proportions with several salts, forming crystallizable compounds in which it plays a part analogous to the water of crystallization. The methylated spirit of commerce consists of a mixture of alcohol of specific gravity 0.830 with 10 per cent. of common wood spirit. This addition of wood spirit scarcely interferes with the employment of the spirit as a solvent, though it renders it unfit for use afterward as a stimulant drink.—Alcohol or spirit of wine is the most important member of a group of compounds which manifest a close analogy with each other, both in chemical composition and in the decompositions of which they are susceptible. The general doctrine of alcohols was introduced into science by MM. Dumas and Peligot. These illustrious chemists, in the course of their investigations into the properties of wood spirit, discovered that vinic alcohol was not a unique body, but that in wood spirit was to be found a compound of similar character, which they therefore called methylic alcohol. Subsequently a long list of bodies properly classed under the generic term of alcohols was discovered by European chemists. As these bodies were found to be closely related to each other and to differ by a common multiple C_2H_4 , they were said to be homologous, because a like description is applicable to each member of the series. The following table includes the most important homologous alcohols:

Methylic alcohol	$\text{C}_2\text{H}_5\text{O}$
Ethylie "	$\text{C}_2\text{H}_5\text{O}$ or $\text{C}_4\text{H}_9\text{O} + (\text{C}_2\text{H}_5)$
Propylie "	$\text{C}_3\text{H}_7\text{O}$ or $\text{C}_6\text{H}_{13}\text{O} + 2(\text{C}_2\text{H}_5)$
Butylie "	$\text{C}_4\text{H}_9\text{O}$ or $\text{C}_8\text{H}_{17}\text{O} + 3(\text{C}_2\text{H}_5)$
Amylie "	$\text{C}_5\text{H}_{11}\text{O}$ or $\text{C}_{10}\text{H}_{21}\text{O} + 4(\text{C}_2\text{H}_5)$
Caproie "	$\text{C}_6\text{H}_{13}\text{O}$ or $\text{C}_{12}\text{H}_{25}\text{O} + 5(\text{C}_2\text{H}_5)$
Caprylie "	$\text{C}_8\text{H}_{17}\text{O}$ or $\text{C}_{16}\text{H}_{33}\text{O} + 7(\text{C}_2\text{H}_5)$
Laurylie "	$\text{C}_{12}\text{H}_{25}\text{O}$ or $\text{C}_{24}\text{H}_{49}\text{O} + 11(\text{C}_2\text{H}_5)$
Cetylle "	$\text{C}_{16}\text{H}_{33}\text{O}$ or $\text{C}_{32}\text{H}_{65}\text{O} + 15(\text{C}_2\text{H}_5)$
Cerylle "	$\text{C}_{27}\text{H}_{55}\text{O}$ or $\text{C}_{54}\text{H}_{109}\text{O} + 26(\text{C}_2\text{H}_5)$
Melissyllie "	$\text{C}_{30}\text{H}_{62}\text{O}$ or $\text{C}_{60}\text{H}_{121}\text{O} + 29(\text{C}_2\text{H}_5)$

ALCONA, a N. E. county of Michigan, on Lake Huron; area, 630 sq. m.; pop. in 1870, 696. It is drained by the Ansable and one of its branches. Alcona lake, in the N. part, empties through Thunder Bay river into Thunder bay. In 1870 there were three schools attended by 137 children.

ALCORN, a N. E. county of Mississippi, bordering on Tennessee; pop. in 1870, 10,431, of whom 2,768 were colored. It was organized in 1870 from portions of Tippah and Tishomingo counties, and was named in honor of James L. Alcorn, governor of the state. The Tusculum and Hatchie rivers intersect the county, and the Memphis and Charleston and Mobile and Ohio railroads run through it. The productions in 1870 were 11,597 bushels of wheat, 226,057 of corn, 14,892 of sweet potatoes, and 2,546 bales of cotton. Capital, Corinth.

ALCOTT, Amos Bronson, an American educator, born at Wolcott, Conn., Nov. 29, 1799. Like many farmers' sons in Connecticut, while still a boy, he was intrusted by a local trader with a trunk of merchandise, with which he sailed for Norfolk, Va., and which he afterward carried about among the plantations; and his early readings were in the planters' houses, who gave him hospitality, and, observing his turn for study, lent him books. On his return to Connecticut he began to teach, and attracted attention by his success with an infant school. He removed to Boston in 1828, and showed singular skill and sympathy in his methods of teaching young children of five, six, and seven years, at the "Masonic Temple," (See "Record of a School," by E. P. Peabody, 12mo, Boston, 1834; also, a transcript of the colloquies of these children with their teacher, in "Conversations on the Gospels," 2 vols. 12mo, Boston, 1836.) But the school was in advance of public opinion, and was denounced by the newspapers. Mr. Alcott gave up the enterprise and removed to Concord, Mass., where he engaged in study, interesting himself chiefly in natural theology and reform in education, diet, and civil and social institutions. On the invitation of James P. Greaves of London, the friend and fellow laborer of Pestalozzi in Switzerland, Mr. Alcott went to England in 1842. Mr. Greaves died before his arrival, but Alcott was cordially received by his friends, who had given the name of "Alcott House" to their school at Ham, near London. On his return to America, he brought with him two of his English friends, Charles Lane and H. G. Wright; and Mr. Lane having bought a farm which he called "Fruitlands," at Harvard, Mass., they all went there to found a new community. Messrs. Lane and Wright soon returned to England, and the farm was sold. Mr. Alcott removed to Boston, and afterward returned to Concord, and has led the life of a peripatetic philosopher, conversing in cities and in villages, wherever invited, on divinity, on human nature, on ethics, on dietetics, and a wide range of practical questions. These conversations, which were at first casual, gradually assumed a more formal character, the topics being often printed on cards, and the company meeting at a fixed time and place. Mr. Alcott attaches great importance to diet and government of the body; still more to race and complexion. Mr. Alcott contributed several papers

entitled "Orphic Sayings" to the "Dial" (Boston, 1839-42), and in 1868 published a volume entitled "Tablets." His latest work, entitled "Concord Days" (1872), contains his personal reminiscences of that town.—**Louisa May**, an American authoress, daughter of the preceding, born at Germantown, Penn., in 1833. She began to write fairy tales in her teens, and her first volume, "Flower Fables," was published in 1855; it was followed by a number of stories written for the Boston journals. Her "Hospital Sketches" (1863), which won for her a general reputation, were made up from letters written home while she was a volunteer nurse in the army at the south. She became a contributor to the "Atlantic Monthly" in 1863-4, and in 1865 published her first novel, "Moods." She wrote "Little Women," the most popular perhaps of all her works, in 1867. This was succeeded by "An Old-Fashioned Girl" in 1869, and by "Little Men" in 1871.

ALCOTT, William Alexander, M. D., an American author, cousin of the preceding, born at Wolcott, Conn., Aug. 6, 1798, died at Auburn-dale, Mass., March 29, 1859. He supported himself until he reached the age of 25 by working on the farm in summer and teaching in winter. Subsequently he studied medicine at Yale college, and after practising about four years he engaged with Mr. Woodbridge, the geographer, in the preparation of school geographies and atlases, and in editing the "Juvenile Rambler," the first weekly periodical for children published in America, and the "Annals of Education." At this time he cooperated actively with Gallaudet, Woodbridge, Hooker, and others, in striving to effect a reform in the public schools of the state. He wrote many articles on this subject for the Hartford and New Haven papers, one of which, "On the Construction of School Houses," gained a premium from the American institute of instruction. In 1832 Dr. Alcott removed to Boston, and published his "Young Man's Guide," which has exerted a great influence in spreading important physiological principles. For more than 20 years he passed his summers in laboring at home with his pen, and his winters in lecturing in different parts of the country, upon the topics which especially occupied his attention. He visited upward of 20,000 schools, before many of which he lectured. He published above 100 books and pamphlets, among which may be specified, in addition to those already mentioned, "The House I Live In," "The Young Woman's Guide," "Young Housekeeper," the "Library of Health" (6 vols.), "Moral Reform," and "My Progress in Error." Dr. Alcott, though the advocate of many opinions which are open to the charge of singularity, was a philanthropist of the genuine stamp, and his name is identified permanently with some of the most valuable reforms in education, morals, and physical training, which the present century has witnessed. The amount of labor which he per-

formed without the expectation of any compensation for his services, is believed to be almost unparalleled. So unintermitting and engrossing were his various avocations, that he hardly ever found time to read a book through; and the books which he wrote probably exceed in number those which he read entirely. Dr. Alcott's views of reform did not lead him to the adoption of any violent and destructive measures. The great object of his labors was to prevent poverty, vice, and crime, by means of correct physical and moral training, and the judicious application of intelligence to the improvement of society.

ALCOY, a town of Spain, in Valencia, in the province and 23 m. N. of Alicante; pop. about 25,000. It is well built, in a picturesque site between two streams, and has extensive manufactures of paper, cloth, linen, and excellent sugar-plums. The best paper for cigarettes is made here.

ALCUIN (Lat. *Flaccus Albinus Alcuinus*), an English scholar and churchman, born probably in York about 735, died May 19, 804. He was master of the school and keeper of the cathedral library at York, until at the invitation of Charlemagne he went to France in 780 and opened a school, probably at Aix-la-Chapelle, where his lessons were attended by the emperor and his court. This establishment is supposed to have been the germ of the university of Paris, and had an important influence upon the revival of learning in France. In 796 he received the abbey of St. Martin of Tours, and soon afterward opened a school there, which became widely celebrated. He was the confidant and adviser of the emperor, and one of the most learned men of the age, but so modest that he refused to accept any higher order in the church than that of deacon. The best edition of his writings, including theological treatises, epistles to Charlemagne, and miscellaneous letters, was published by Froben (2 vols. folio, Ratisbon, 1777).

ALCYONE, the brightest of the star group of the Pleiades, and the supposed centre of the arc in which our sun and planets appear to be moving through the interstellar space.

ALDAN. **I.** A name applied by some geographers to the whole range of mountains in eastern Siberia, from the Altai chain to Behring strait. Others limit its application to a branch of this mountain system, extending from the Yablonnoy range in a northwesterly direction about 900 miles. Mt. Kapitan, the highest summit of this branch, has an elevation of 4,263 feet above the sea level. **II.** A river, which rises in the Aldan mountains, and after a N. and W. course of about 900 miles falls into the Lena, 100 miles N. of Yakutsk.

ALDBOROUGH, a market town and parish of Yorkshire, England, on the Ure, 16 m. W. N. W. of York. The town is a place of great antiquity, supposed to have been the capital of the Brigantes, known to the Romans as Isurium. Several remains of antiquity have been

discovered. Three remarkable obelisks of rough stone are in the neighborhood, the highest of which is 30 feet high.

ALDEBARAN, the chief star in the constellation of Taurus, forming the eye, and one of the group of five called the Hyades. Huggins has lately proved by means of the spectroscope that this star has nearly the same chemical composition as our sun, from which other stars differ considerably.

ALDEGONDE, *Sainte*, **Philip van Marnix**, baron of, a Dutch statesman and scholar, born in Brussels in 1538, died in Leyden, Dec. 15, 1598. At Geneva, where he was educated, he imbibed from Calvin a strong attachment to the reformed creed, and after his return home he was one of the signers, if not the originator, of the pact of the nobles protesting against the establishment of the inquisition in the Netherlands in 1566. He was the especial friend of William of Orange, who confided to him several delicate missions, and sent him in 1572 to the first assembly of the Dutch states general at Dort. He was also military commandant of several towns, and in 1573-'4 was for some time a prisoner in the hands of the Spaniards. He was afterward sent by the states general as envoy successively to Paris, to London, and to the diet of Worms (1577). In 1584, being burgomaster of Antwerp, he defended the city against the duke of Parma, but was at last obliged to surrender, after which he spent several years in retirement. In 1590 he was ambassador to France. He left several controversial treatises and an excellent metrical version of the Psalms, and at the time of his death was translating the Bible into Flemish.

ALDEGREVER, or *Aldgraf*, **Heinrich**, a German painter and engraver, born at Paderborn in Westphalia in 1502, died about 1560. He was a pupil and imitator of Albert Dürer. His prints, which are very numerous, are sharp and angular in outline, and generally small.

ALDEHYDE, a liquid obtained from alcohol. Liebig was the first to study the products formed by abstracting hydrogen from alcohol, and to give the name of alcohol dehydrogenated to the first of the series. If vinic alcohol be burned at a low temperature and with a limited supply of air, the vapors emitted have a peculiar irritating effect on the eyes and nose, due to the production of a remarkable body named aldehyde. Similar compounds are furnished by the imperfect combustion of the other alcohols, so that there are as many aldehydes as there are alcohols. There are numerous ways of preparing ordinary aldehyde, among which may be mentioned the oxidation of alcohol by platinum black, chromic acid, nitric acid, chlorine water, and a mixture of sulphuric acid and black oxide of manganese. The method usually employed is to distil 2 parts of 80 per cent. alcohol, 3 parts oil of vitriol, and 2 parts of water into a well cooled receiver. After about 3 parts have passed over, the distillate is mixed with an equal weight of chloride of

calcium and further distilled until $1\frac{1}{2}$ part has passed over. It is further rectified by mixing 1 volume with 2 volumes of ether surrounded by cold water, and passing ammonia through it to saturation. Crystals of aldehyde-ammonia separate, which are washed with absolute ether and dried; by subsequently distilling these crystals with sulphuric acid and a little water, pure anhydrous aldehyde is obtained. Aldehyde as commonly known is a thin, transparent liquid, with a strong, suffocating odor. It boils at 69.5° F. It dissolves sulphur, iodine, and phosphorus; absorbs dry sulphurous acid; forms definite compounds with the acid sulphites of the alkali metals; and reduces salts of silver. Upon this last property is founded the manufacture of silver mirrors by the reduction of nitrate of silver and the deposition of the metal upon glass.

ALDEN, John, one of the first settlers of Plymouth, New England, was a magistrate in that colony for more than half a century, and died in 1687, aged about 89. On behalf of Miles Standish, Alden once proposed marriage to a pilgrim lady, who replied, "Prithce, John, why do you not speak for yourself?" The query led to John's becoming the lady's husband. This incident has been made the subject of a poem by Longfellow.

ALDENHOVEN, a town in Rhenish Prussia, on the road from Jülich to Aix-la-Chapelle; pop. in 1867, 3,041. It is noted for a victory of the Austrians under the prince of Coburg over a part of the French army under Dumouriez, March 1, 1793, the result of which was the occupation of Belgium by the allies. In October of the following year the vicinity of Aldenhoven again became the scene of considerable fighting between the Austrians and French, under Clairfait and Jourdan respectively, the result being in favor of the republican army.

ALDER (*alnus*), a genus of plants belonging to the natural order *betulacea*. It has four stamens, and its fruit is without wings, by which characteristics it is distinguished from the birch, with which it was classed by the earlier botanists. The principal species are found in North America, though some of its varieties are met with on the eastern continent. The common alder (*A. glutinosa*) grows in moist localities, especially on the higher portions of swampy grounds, which are free from standing water. This tree is applied to many valuable purposes of practical utility. Its wood is prized by machinists as adapted to mill wheels and other work which is mostly under water. It is also in request for certain branches of cabinet-making and turnery. The charcoal made from its wood is of an excellent quality, and is highly esteemed for the manufacture of gunpowder. The bark, which contains an astringent juice, is used for tanning, and, with the addition of copperas and other ingredients, forms a dye for several colors. The alder is also an ornamental tree, with its abundant foliage of deep green. The Turkey alder (*A.*

Alder—Catkins and Seed.

incana) is abundant in the north of Europe, and is found to the east, even beyond the Caucasus. It is a taller and more erect tree than the common alder, and possesses many of the same properties, although it grows well in situations that are comparatively free from moisture. A beautiful species, *A. cordifolia*, or heart-leaved alder, is a native of Italy. The alder is easily cultivated, and, although not rapid in growth, can be obtained from seed with a great degree of certainty.

ALDERMAN, a title derived from the Saxon *caldorman* (elder man). The term *caldor* was in itself a title of honor, used like the word "elder" in Scripture; but the title *caldorman* implied a higher degree of honor, and was among the Saxons applied generally to the chief dignitaries of state and the nobility, and specifically to certain national, county, and municipal officers, whose functions appear to have been chiefly judicial, but are not clearly defined. In modern times the alderman is a legislative and judicial officer of municipal corporations, elected or appointed according to the constitution or charter of the city in which he holds his office.

ALDERNEY (Fr. *Aurigny*), the northernmost of the Channel islands, and the nearest to the French coast, separated from it by the race of Alderney (a strait which is very dangerous in stormy weather), about 7 m. W. of Cape La Hague, the N. W. extremity of Normandy, and 24 m. W. N. W. of Cherbourg. It is about 4 m. long from N. E. to S. W. and $1\frac{1}{2}$ m. wide; area, 1,962 acres; pop. in 1871, 2,718. There are picturesque cliffs on the S. E. coast, the highest of which is 281 ft. There are several bays, but none safe and capacious enough for large vessels; and the English government has recently erected a granite breakwater off the harbor of St. Anne at a cost of £1,250,000, which, however, has not proved so useful as was anticipated. A series of forts was constructed around the island at the same time; also a

railroad along the N. E. coast. St. Anne, the chief town (commonly called the Town), is in a beautiful valley nearly in the centre of the island. The inhabitants principally live by fishing and agriculture. The Alderney cow is small and graceful in form, of dun or tawny color, and remarkable for milking qualities. About 6 m. from Alderney to the west are the Caskets, a cluster of dangerous rocks, on which there are three lighthouses forming a triangle. Upon these rocks Prince William, son of Henry I., with a retinue of above 140 young noblemen, of the principal families of England and Normandy, perished in 1120; and in 1744 the Victory, of 110 guns, with a crew of 1,100 men, was totally lost.—Together with the other Channel islands, Alderney formed a dependency of the Normans, and passed to the crown of England. It is itself a dependency of Guernsey. The civil power of Alderney is, under the peculiar constitution of the Channel islands, vested in a judge appointed by the crown and six jurats chosen by the people for life. These, with 12 douzainiers, also chosen by the people and the governor, form a legislature in which the douzainiers deliberate, but neither they nor the governor may vote. The jurats, with the king's advocate and the greffier or registrar, constitute the court of justice, from which an appeal lies to the royal court at Guernsey, and in the last resort to the king in council. In criminal cases the court at Alderney is only a preliminary tribunal, the court at Guernsey having the final determination of the cause.

ALDERSHOTT, an English military camp of instruction, in Hampshire, 50 m. by rail S. W. from London, established in 1854-'5 on Aldershott common, a broad tract of sandy land. Near the site of the old village of Aldershott an entirely new town has sprung up, and the population of the parish has increased from about 900 in 1852 to over 20,000 in 1872, chiefly soldiers and persons connected with the military and civil services. A broad military road separates the town from the camp, which consists of N. and S. sections, divided by the Basingstoke canal, extending over an area of seven square miles, with accommodation for at least 20,000 soldiers. The structures consist of long rows of wooden huts for the soldiers permanently stationed there, around which they cultivate gardens; the headquarters, a substantial brick building; several churches, a permanent barracks, hospitals, places of recreation, &c. The cost of establishing this national military depot has already considerably exceeded £1,000,000. During the last five years annual reviews have taken place here between the months of June and September; two or more regiments of the volunteer forces being detailed, in their turn, to coöperate with the regulars, and thus gain a practical knowledge of military duty in the camp and on the field.

ALDHelm, an English divine and writer during the Saxon heptarchy, born about 656, died in 709. He was a relative of the king of the

West Saxons. He is said to have been the first Englishman who wrote Latin poetry. About 685 he became the first abbot of Malmesbury, and in 705 the first bishop of Sherborne (afterward the bishopric of Salisbury). He is chiefly known by his two works *De Virginitate*, in prose (published by Wharton, 1693), and *De Laude Virginum*, in verse.

ALDINE EDITIONS, works which proceeded from the press of the Manutii (Aldus the Elder, Paulus, and Aldus the Younger), a celebrated family of printers in Venice during the 15th and 16th centuries. (See MANUTII.) The Aldine editions comprise the ancient classics, and the works of Petrarca, Boecaccio, Dante, and others. The editions of the senior Aldus, who founded the business in 1490, are the most esteemed. Spurious works with the imprint of the Aldi are by no means uncommon, as they were counterfeited even in their own time, and very extensively at later periods. The great perfection which has been attained in the art of printing, and the attention which has been given, especially during the present century, to the reprint of the classics, have considerably diminished the real value of the Aldine editions, although rare specimens are still much sought for by collectors. The library of the late archduke of Tuscany contains, it is believed, the most perfect collection of Aldine works; but they are met with in most of the great libraries, as the Bodleian at Oxford, the national library at Paris, and the British museum. A. A. Renouard made a complete collection and published a catalogue of them in his *Annales de l'imprimerie des Aldes* (Paris, 1803 and 1834).

ALDINI. **I. Antonio**, count, an Italian statesman, born in Bologna in 1756, died in Pavia, Oct. 5, 1826. When Bologna in 1797 was wrested by General Bonaparte from the papal government, Aldini, who was then professor of jurisprudence, was sent to Paris by his fellow citizens. He was chosen president of the council of the ancients in the Cisalpine republic, and was held in much esteem by Napoleon, who in 1805 created him a count, and made him a minister of state for the kingdom of Italy. After the fall of Napoleon and the reestablishment of the former rulers in Italy, he resided in Lombardy. **II. Giovanni**, brother of the preceding, and nephew of Galvani, born in Bologna, April 10, 1762, died in Milan, Jan. 17, 1834. He was professor of natural philosophy at Bologna, Italian counsellor of state, and knight of the order of the iron crown. He is well known by his works (written in Italian, French, and English) on the practical applications of galvanism, illumination, tides, means of safety from fire, &c. He prepared a scheme for turning to profit the rise and fall of the tide in the lagoons of Venice in working mills; and is also said to have been the inventor of articles of fire-proof clothing.

ALDOBRANDINI, a noble family of Florence in the 16th and 17th centuries. **SILVESTRO**, a cele-

brated jurist, was born at Florence in 1499, and died in Rome in 1558. Being opposed to the duke Alexander de' Medici, he was banished from Florence in 1530. Of his three sons, GIOVANNI was auditor rote and cardinal, and is also known as an author; IPPOLITO became pope under the title of Clement VIII.; and TOMMASO, born at Rome about 1540, was papal secretary of briefs, and left a translation of the "Lives of the Philosophers" by Diogenes Laërtius, and a commentary on Aristotle, *De Physico Auditu*. CINZIO PASSERO, who died at the beginning of the 17th century, was the son of Silvestro's daughter, took the name of Aldobrandini, and was made cardinal. He was a friend of Tasso, who dedicated to him the *Gerusalemme conquistata*. His brother PIETRO was also a cardinal, and legate in France, where he composed the differences between Henry IV. and the duke of Savoy in 1601. The family disappeared in 1681.

ALDRICH, Thomas Bailey, an American poet, born in Portsmouth, N. H., in 1836. After commencing a course of study preparatory to entering college, upon the death of his father he abandoned this purpose to enter the counting room of an uncle, a merchant in New York. Here he remained three years; and it was during this period that he began to contribute verses to the New York journals. A collection of his poems was published in New York in 1855, the volume taking its name from the initial piece, "The Bells." Mr. Aldrich's most successful poem, "Babie Bell," which was published in 1856, was copied and repeated all over the country; and perhaps it was the favor with which it was received that induced him to abandon mercantile pursuits for a literary career. He became a frequent contributor to "Putnam's Magazine," the "Knickerbocker," and the weekly newspapers, for one of which he wrote "Daisy's Necklace, and What Came of It," a prose poem which was afterward issued in a volume, and attained a wide popularity. In 1856 Mr. Aldrich joined the staff of the "Home Journal," which was then under the charge of N. P. Willis and George P. Morris, and continued in this position for three years. His pen was always busy during this period, and many of its products became popular favorites. The volumes published by him since 1855 are: "The Ballad of Babie Bell and other Poems" (1856); "The Course of True Love never did Run Smooth" (1858); "Pampinea and other Poems" (1861); "Out of his Head, a Romance in Prose" (1862); a collection of poems (1863); and a volume of poems published in Boston in 1865. Among his later works is "The Story of a Bad Boy," which is to some degree autobiographical. This attracted wide attention as a serial in "Our Young Folks," and was issued in book form in 1870. Mr. Aldrich has been chief editor of "Every Saturday" from its foundation, and has also made occasional prose contributions to the "Atlantic Monthly" and other magazines.

ALDRIDGE, Ira, called the African Roscius, an American actor, born at Bellair, near Baltimore, Md., about 1810, died in Poland, Aug. 7, 1867. He was a mulatto, whose real name is said to have been Hewlett, and in his youth was apprenticed to a ship carpenter. From association with the German population, which is very large on the western shore of Maryland, he learned to speak the German language familiarly, and he also picked up a fair education. When Edmund Kean was in the United States, after the troubles which occurred during 1826 in consequence of the Cox difficulties, Aldridge became his personal attendant, and is said to have accompanied him to England, where a natural talent for the stage was cultivated. He returned to the United States after a short absence, and some time subsequent to 1830 appeared in Baltimore, at a theatre then known as the Mud theatre, which subsequently belonged to Junius Brutus Booth, the tragedian. He appears not to have been successful. There is no account of his having appeared in any other city in America, whence after a short time he returned to England. He began his career in some of the minor theatres of London, and afterward performed in Ireland (with Kean) and all over Europe, being greatly admired, especially in Germany, in Shakespearian characters. In 1861 he created a sensation at Versailles by his personification of Othello in English, the rest of the company speaking French. He was making a journey to Russia when he died. He married a white woman, but his domestic life was unhappy.

ALDROVANDUS, Ulysses (Ital. *Ulisse Aldrovandi*), an Italian naturalist, born at Bologna, Sept. 11, 1522, died Nov. 10, 1607. He took his degree in medicine in 1553, was made lecturer on natural history, and in 1568 persuaded the senate of Bologna to establish a botanic garden. He investigated meanwhile the phenomena of the external world with indefatigable zeal, making journeys and employing collectors. He published works (in Latin) on birds, on insects, and on the lower animals, and after his death the profusion of materials which he had brought together was arranged in additional volumes.

ALE. See BEER, and BREWING.

ALEANDRO, Girolamo, an Italian prelate and scholar, born Feb. 13, 1480, died Jan. 31, 1542. He was early distinguished for great and varied learning, and was associated with Aldus Manutius and Erasmus at Venice. In 1508 Louis XII. called him to Paris, where he became rector of the university. He was afterward chancellor of the bishopric of Liège, in 1517 librarian of the Vatican at Rome, and in 1520 papal envoy to Germany to oppose Luther's heresy, which he did especially at the diet of Worms in the following year. Clement VII. made him archbishop of Brindisi and papal nuncio in France, and in company with Francis I. he was taken prisoner at Pavia in 1525, and ransomed. In 1531 he was again papal

nuncio in Germany, and afterward in Venice, and in 1538 he was made cardinal. Of his numerous writings none were published but a Greek-Latin lexicon, an abridged Greek grammar, and a short Latin poem.

ALECTO, in Greek mythology, one of the Eumenides or Furies. (See EUMENIDES.)

ALEGAMBE, Philippe, a Belgian Jesuit, born in Brussels, Jan. 22, 1592, died in Rome, Sept. 6, 1652. He taught philosophy at the college of Gratz, but finally settled at Rome, where he became superior of the house of the Jesuits, and secretary to the general of the order. Alegambe continued and improved the *Bibliotheca Scriptorum Societatis Jesu*, begun by Ribadeneira and completed by Nathaniel Sotwell. He also wrote two biographical works on Jesuit martyrs to their faith and to their zeal in works of charity, and a life of Cardan.

ALEMAN, Mateo, a Spanish novelist, born in Seville about the middle of the 16th century, died probably in Mexico. In 1568 he was commissioner of finance in his native land, but being falsely accused of maladministration, he was removed from public service, and suffered a long imprisonment. He then betook himself to literature. The first volume of a humorous romance, entitled *La vida y hechos del picaro Guzman de Alfarache*, which he published in 1599, passed through 26 editions within the following six years, besides being translated into the French and Italian. A continuation appeared in 1603, which Aleman repudiated; and the genuine second part was published in Valencia in 1605, but the work was never completed. Aleman afterward went to Mexico, but of his subsequent career nothing is known.

ALEMANNI, or Alamanni (Ger., all men), a confederacy of warlike German tribes, with whom the Romans first came into collision in the reign of Caracalla. They then dwelt on the Main, and subsequently spread toward the Danube, the Helvetian Alps, and across the Rhine into eastern Gaul. The Tencteri and Usipetes, who previously inhabited the territories of modern Westphalia, are supposed to have formed the nucleus of the confederation. Caracalla made an unsuccessful campaign against the Alemanni in 214, and boastfully assumed the surname Alemannicus. Alexander Severus and Maximin also fought against them, without impairing their growing power. During the joint reign of Valerian and his son Gallienus they crossed the Rhetian Alps, invaded Cisalpine Gaul, and advanced as far as Ravenna, but were repulsed, and subsequently suffered greater defeats at the hands of the emperors Aurelian and Probus. In the 4th century they made constant inroads into Gaul, but were chastised by Constantius Chlorus, Julian, Valentinian I., and Gratian; in spite of which, however, their power continued to increase. They were at that period united with the Suevi, a kindred nation, with whom they gradually became more and more confounded, until both nations were subdued by the Franks under

Clovis. The northern portions of the Alemannic territories remained a domain of the Frankish kings; the rest was afterward formed into a Germanic duchy of Alemannia, between the Alps, the Jura, the Vosges, the Neckar, and the Lech, the eastern part of which finally assumed the name of Swabia (Suevia). The Swabian dialect of the German language is known as the Alemannic.

ALEMBERT, Jean le Rond d', a French mathematician and man of letters, born in Paris, Nov. 16, 1717, died there, Oct. 29, 1783. He was the illegitimate child of the poet Desfontaines, commissary of artillery, and Madame de Tencin, a court lady, more celebrated for wit and beauty than for virtue. The infant, exposed on the steps of the church of St. Jean le Rond, was picked up by the police, and given to a glazier's wife, to whose affection the great philosopher responded throughout his life. He lived with her for 40 years, and when in the days of his tame Madame de Tencin came forward and avowed her relationship, he repudiated her, alleging that she was but a stepmother, and the glazier's wife his real parent. Soon after his discovery his father acknowledged him and settled upon him a pension of 1,200 francs, which was sufficient to provide for his education. In 1721 he was sent to a boarding school. At the age of 12 he was transferred to the Mazarin college of Paris. His philosophical studies here were eminently successful. He was for some time restrained from the study of mathematics, and applied himself to law, which he soon abandoned for medicine; but the irrepressible bent of his mind overcame all obstacles, and he at last betook himself with renewed ardor to his favorite employments. A memoir and some remarks on the *Analyse démontrée* of Reyneau procured him the membership of the academy of sciences in 1741. His celebrated *Traité de dynamique* appeared in 1743, and created a new branch of science. In 1744 he published his *Traité de l'équilibre et du mouvement des fluides*. In 1746, the Berlin academy of sciences having proposed the general causes of the winds as the subject for the prize essay, D'Alembert's treatise gained him the prize and the membership of the academy; in this he attributed the currents to the combined influence of the sun and moon in creating an action resembling the flux and reflux of the tides. In 1754 he became a member of the French academy, and in 1772 its perpetual secretary, and within the next three years wrote historical eulogies upon 70 members deceased since 1700, which were published in 6 vols. 12mo. He was early connected with the freethinkers of his age in the preparation of the *Encyclopédie*, and his *Discours préliminaire* was designated by his associate editor Condorcet as a production of which only one or two men in a century could be found capable. The progress of the work was interrupted by the government at the end of the second volume, at which time

D'Alembert finally withdrew from the editorship, but continued to write the mathematical articles. He was a member of most of the learned societies of Europe, and was in intimate personal communication with Frederick the Great, who invited him to reside at the court of Berlin. This, however, he declined. The empress Catharine offered him the post of tutor or governor to the czarevitch, with an income of 100,000 livres, but this he also declined. He was a man of singularly independent mind and manners, without degenerating into discourtesy or indifference to the feelings or necessities of others. His connection with the *Encyclopédie* involved him unjustly in the general censure which attached itself to the impiety and intolerance of many of its contributors. D'Alembert's means were limited and insufficient to keep pace with his benevolence; for when only in the enjoyment of two pensions of about \$500 a year, one from Frederick, and the other from his own country, he gave away more than half their amount in charity. His grief on the death of Mlle. de l'Espinasse, for whom he entertained a strong attachment, which she requited with less ardent sentiments, is believed to have hastened his death. Among his works not already mentioned are: *Recherches sur différents points importants du système du monde* (3 vols. 4to, 1754-'6); *Opuscules mathématiques* (8 vols. 4to, 1761-'80), a rich mine of original materials; *Éléments de musique*, upon the system of Rameau; *Mélanges de littérature et de philosophie* (5 vols. 12mo); *Sur la destruction des Jésuites en France*; and a life of Queen Christina of Sweden. No single collection of his mathematical works has been published, but Bastien collected his literary and philosophical writings in 18 vols., with a full life of the author prefixed (Paris, 1805). A more complete edition was published by Bossange in 5 vols. 8vo (1821), containing several pieces not before published, and the correspondence of D'Alembert with Voltaire and Frederick II.

ALEMBIC (Arab. *al*, the, and Gr. *ἀμβίξ*, a cup), one of the oldest forms of vessels used for distillation, and the type of all later kinds of apparatus for the same purpose. It consists

of a vessel in the form of a flask with wide neck, on which is fitted a head connected with a downward running tube, the whole so arranged that all vapors condensed against the inside of the head run through a surrounding gutter to the tube and so into a receiver. Our engraving represents a glass alembic on a stand, heated by a spirit lamp, and connected with the

receiver, which is supported on a separate stand. Notwithstanding this apparatus is at present little used in its original shape, and is

superseded by the retort, it must be confessed that it has its advantages, and was especially adapted for the class of researches with which the alchemists occupied themselves. These advantages are that the head can be separated from the body, which is very convenient for the introduction of solid or semi-fluid substances, and also for cleaning out after the operation. In some manufacturing processes alembics are still employed, as in that of hydrocyanic acid. In France they are still more employed than elsewhere; but it must not be forgotten that the French call nearly all kinds of distilling arrangements alembics, so that many of their so-called alembics are very different from the apparatus here described.

ALEMTEJO, the largest province of Portugal, bounded by Estremadura, Beira, Spain, Algarve, and the Atlantic ocean; area, 9,416 sq. m.; pop. in 1868, 332,237. The surface on the E. is traversed by irregular chains and groups of hills, which in the western section almost entirely disappear. On the southern border the Algarvian chain rises to the height of 4,000 feet. The principal rivers are the Guadiana, Tagus, and Sadão. The climate on the barren plains of the S. and W. is hot and dry. In the E. it is more salubrious and the soil more fertile, yielding good crops of wheat, barley, rice, and maize. The vine is universally cultivated. The citron, lemon, figs, and pomegranates abound. Attention is paid to the breeding of sheep, hogs, and goats. In a few places there are manufactures of woollen cloths and of earthenware. Alentejo is divided into the three districts of Portalegre, Evora, and Beja, so called after their chief towns. Capital, Evora.

ALENÇON, a town of France, in Normandy, capital of the department of Orne, on the Sarthe, 116 m. W. S. W. of Paris; pop. in 1866, 16,116. It has a considerable inland trade, and is known for the famous lace, *point d'Alençon*. The fabrication of this costly article, however, now gives employment to a comparatively small number of families, in which it is an hereditary occupation. The trade was one of the forced productions of Colbert, who gave a monopoly of it for ten years, and a bounty from the crown. The inhabitants are generally engaged in making muslin, embroidery, leather, glass, and iron. Alençon is mostly built of granite, and has a cathedral, library, museum, college, theatre, and annual horse races. Its counts were conspicuous in the history of Normandy and of France from the 10th century. In 1219 it was made an apanage of the French crown, with lords of the royal family; and in the 15th century it was erected into a royal duchy. The second son of the duke de Nemours, born in 1843, now bears the title of duke d'Alençon.

ALENÇON, François, duke of. See ANJOU.

ALEPPO (Arab. *Haleb*; anc. *Chalymphon*, afterward *Beræa*), a city of N. Syria, capital of a Turkish vilayet of the same name, in lat. 36°

11° N., lon. 37° 10' E., on the borders of the Syro-Arabian desert, about 60 m. E. of Antioch and 70 m. from the Mediterranean. The population, formerly estimated at upward of 200,000, has been reduced by earthquakes, and now numbers about 100,000, including 16,000 Christians and 4,000 Jews; the rest being Greeks, Armenians, Arabs, and Turks. The city is encompassed by low and barren hills and irregular mounds, intersected by fertile valleys. The gloomy aspect of the projecting chalk rocks is relieved by gardens along the rivulet Nahr Kowaik, planted with the celebrated pistachio trees and abounding in exquisite fruits and flowers. Including the straggling suburb, the circumference of Aleppo is 5 to 6 m., but the city proper is not over 3 m. in circuit, and it is shut in by a ruinous Saracenic wall. Aleppo is a city of a thoroughly oriental type, with extensive bazaars, numerous mosques, and a population remarkable for its elegant bearing. The streets are better than those of most eastern cities, though many of them are arched over. The houses are of stone, substantially built, with terraces for evening promenades. The commerce, though considerably less than formerly, is still active, the value of the imports in 1866, chiefly English, being \$6,500,000, and of the exports, \$2,700,000. The trade in Aleppo broads and silks has declined since the introduction of European silks. The principal exports are wool, cotton, pistachio nuts, oil, cereals, &c. Aleppo, being on the only safe route between Syria and eastern Asia, is the great centre of the Damascus and Bagdad caravans.—The name of Haleb is traced by some Arab philologists of the 14th century to the days of Abraham, who, according to this tradition, stopped there on his way to Canaan, distributing milk to the poor and repeating the words *Ibrahim aleb*, "Abraham has milked." In 638 Aleppo was taken from the Byzantine empire by the Arabs and made the seat of a sultanate. It was reconquered by John Zimiscees, and afterward became the capital of the Seljuk Turks. After being besieged by the crusaders, desolated by the followers of Timour, and destroyed several times by earthquakes, it became, after the Turkish conquest at the beginning of the 16th century, a prosperous city, and the seat of a branch of the Levant company. In 1850 it was the scene of massacres of Christians, and of revolts, which were suppressed in November with the aid of Generals Bem and Guyon, then in Turkish service. Prelates of the Roman Catholic, Greek, Armenian, and Syriac churches, and consuls of the principal Christian nations, reside here. The place has been often visited by the plague and the cholera.—A disease of the skin called the Aleppo button (Arab. *hebbet*), or boil, attacks most of the residents, and is attributed to the unwholesome water. The natives generally have it in infancy, and chiefly in the face. The eruption makes its appearance in

the form of a small, hard, red tubercle, increasing in size after several weeks, discharging pus, and eventually forming a scab, which on disappearing leaves an indelible mark. Dogs and cats are commonly attacked by it in the nose. Strangers are attacked sometimes soon after their arrival, sometimes not until years after their departure. The malady, which usually lasts a year, prevails all along the adjacent rivers, and along the valley of the Euphrates, as far as Bagdad.

ALESKI (formerly *Dnieprovska*), a town in S. Russia, in the government of Taurida, on an arm of the Dnieper, 5 m. S. E. of Kherson; pop. in 1870, 8,484, and rapidly increasing.

ALESIA, a fortified town of the Mandubii, in Celtic Gaul, renowned for its siege by Caesar in 52 B. C. It was a very old town, built on a high hill, washed by the Lutosa and Osera (believed to be the Oze and Ozeraine, in Côte d'Or), near the sources of the Sequana (Seine). Its fall, and the surrender of Vercingetorix, who defended it, decided the subjugation of Gaul. It was destroyed by Caesar, but was subsequently rebuilt, and became a very considerable city under the Romans. It was ruined by the Normans in the 9th century. At the foot of the hill (Mont Auxois) now stands the village of Alise Ste. Reine, 6 m. S. of Montbard.—M. Delacroix, an architect of Besançon, called attention in 1855 to the village of Alaise, near Ornans, in the department of Doubs, as the site of the battlefield of Alesia. Excavations were made at Alaise and at Alise, at the latter place under the auspices of Napoleon III., and archaeological evidence was produced in support of the two localities, that respecting Alise Ste. Reine being regarded as conclusive in favor of this site by F. de Sauley and other competent persons who conducted the researches there in 1861. Many works have been written on this controversy. The most important publications in behalf of Alaise are four by J. É. J. Quicherat (Paris, 1857-'62); in favor of Alise, by Rossignol (Dijon, 1856), the duke d'Aumale (Paris, 1858), and F. de Sauley (1862). The academy of inscriptions and belles-lettres conferred a prize upon Rossignol's essay. In 1862 M. Grivot published his opinion that the battle of Alesia was fought neither at Alise Ste. Reine nor at Alaise, but at Alise-Izernore, in the department of Ain.

ALESSANDRESKU, Gregory, a Roumanian poet, born at Tergovist, Wallachia, about 1812. After a short service in the army, he became conspicuous as a liberal politician, and was banished to a monastery for publishing satires and fables reflecting upon the government. In 1859 he was for a short time minister of finance. A second edition of his most important work, entitled "Reminiscences, Impressions, Letters, and Fables," was published at Bucharest in 1863.

ALESSANDRI, Basil, a Roumanian poet of Venetian origin, born in Moldavia in 1821. He was educated at Jassy and Paris, joined the

party of young Roumania, and produced ballads and plays which are popular in Moldo-Wallachia. His principal works have been published at Jassy, Bucharest, and Paris (1852-'63). After the death of his father he emancipated all his serfs, and his example was followed by nearly 1,000 other serf-holders previous to the act of general emancipation promulgated by Prince Gregory Ghika. In 1859-'60 he was minister of foreign affairs. He published in French a collection of *Ballades et chants populaires de la Roumanie* (Paris, 1855).

ALESSANDRIA. I. A N. W. province of Italy, in Piedmont, embracing the former duchy of Montferrat; area, 1,952 sq. m.; pop. in 1872, 683,473. It is traversed E. and W. by the Turin and Stradella, and N. and S. by the Genoa and Lago Maggiore railroad. The principal rivers flowing through it are the Tanaro, Bormida,

and Scrivia. Among the chief products are maize, wine, silk, madder, and flax. The eastern part is an extensive, fertile plain; the centre consists partly of barren hills, and partly of excellent table land; the western portion is hilly, and produces the best wine of Piedmont. It is divided into the districts of Tortona, Alessandria, Asti, Casale, Acqui, and Novi. II. A fortified city (Ital. *Alessandria della Paglia*, of the straw, from its houses having originally been thatched), capital of the above province, near the confluence of the Bormida and Tanaro, a few miles from the Po, and 46 m. E. S. E. of Turin; pop. in 1872, including suburbs, 57,079. It was founded in 1168 by the Lombard league, as a bulwark against the German emperors, and in modern times again received significance as a national Italian fortress against Austria. Though up

Alessandria.

to the beginning of this century its defences were indifferent, the French in vain besieged it in 1657, and Prince Eugene of Savoy in 1707 only took it after a protracted defence. Napoleon I. strengthened it, after the annexation of Piedmont to France, with casemated batteries for the defence of the ditch, great additions to the citadel, and a bridge-head on the opposite side of the Bormida. It is now the strongest fortified city of Italy, after Verona. During the war of 1848-'9 it was the principal arsenal of the Italians, and after the battle of Novara it was temporarily occupied by an Austrian force during the truce. It was the headquarters of Napoleon III. and Victor Emanuel in the campaign of 1859. The city has a college, a theological seminary, about 20 churches, including a cathedral, an academy of science and arts, several palaces, and manu-

factories of linen, silks, cloths, and wax candles. It is an important railway centre.

ALEUTIAN ISLANDS, a chain of islands situated between Alaska and Kamtchatka, and separating Behring sea from the North Pacific ocean, between lat. 51° and 56° N., and lon. 163° and 188° W. The origin of the name is unknown, but is believed to be Russian. Although the Aleutian chain is usually regarded as co-extensive with the Catharine archipelago, an appellation applied to all the islands of this region in honor of Catharine II. of Russia, some geographers do not include in it Behring island and Copper island, near the Asiatic coast. These are known as the Komandorski or Commander's islands, and are situated in about lon. 193° W.; the Russian explorer Behring died upon that which bears his name. Omitting them, the Aleutian islands consist of

four groups, as follows: 1, the Nearer (Blizhni) or Sasignan islands, 5 in number, which lie W. of the 185th parallel of W. longitude, and derive their name from their proximity to Kamtehatka; 2, the Rat (Krisi) islands, of which there are 15, situated between lon. 185° and 180° W.; 3, the Andreanovski group, extending from lon. 180° to 172° W., and containing 30 islands, on one of which, Goreloi (Burnt) island, is a mountain 8,000 feet in height; and 4, the Fox (Lisi) islands, numbering 31, lying between lon. 172° W. and the shore of the American continent, and including Unimak and Unalashka. The entire area of the islands is 6,391 geog. sq. m. Dall estimates the native population at 1,500, though it probably was not less than 10,000 when the Russians first occupied the country. The half-breeds and resident Russians do not exceed 300 in number. Unimak is the largest island of the chain and the most mountainous. Unalashka contains the greatest number of inhabitants and the finest land for agricultural purposes, and also possesses the best anchorage and principal port, Iliuliuk or Captain's Harbor. Traces of the action of subterranean igneous forces are nearly everywhere apparent, and the whole archipelago is believed to be the result of volcanic upheaval. Hot springs are of frequent occurrence. Of the numerous mountains, several are upward of 5,000 ft. high, and many are volcanoes, some of which show slight signs of activity. A rolling country, with hills of moderate elevation, intervenes between the mountains and the coast, which on most of the islands is abrupt and accessible from the sea at comparatively few points. The soil in many districts is fertile, and produces turnips, carrots, parsnips, and cabbages of fair quality, as well as a few potatoes. There is a most luxuriant growth of wild grass suitable for cattle, of which, however, very few are kept, owing to the difficulty of housing them in winter from the scarcity of wood for building purposes. The islands are entirely destitute of timber. The climate is moist and equable, with an average annual temperature of from 36° to 40°. The Aleuts resemble the North American Indians in color and other respects, but are variously regarded as of American and Asiatic origin. An active and formerly a cheerful race, their character has acquired a degree of sombreness from the forced adoption of Russian manners, customs, and religion. Their principal occupations are hunting and fishing.—The Aleutian islands were discovered by Behring in 1741, and subsequently in the same century were acquired and occupied by Russia, together with her possessions on the American mainland. In 1867 they were transferred with the latter to the United States, and now form a part of the territory of Alaska.

ALEWIFE, a fish of the genus *alosa* (*A. tyrannus*, Latrobe), also called spring herring, and in the British provinces gaspereau, or American alewife. It appears in great num-

bers in Chesapeake bay from the south in March, on the New York and New England coasts with the shad in April, and in the British provinces about May 1. Like the shad, it ascends the northern rivers to deposit its spawn. In the bay of Fundy the alewife is abundant; in the gulf of St. Lawrence it is less common, and of smaller size; the bay of Miramichi appears to be its extreme northern limit. It ascends rivers generally to the head of the tide, and returns to the sea in July. The fishery is prosecuted with small meshed seines drawn across the streams, and so successfully that hardly a fish escapes; the fishing lasts about six weeks, commencing as soon as the rivers are clear of ice. It prefers a soft, muddy bottom, and turbid water, and its favorite food is shrimps and the shad worm. The length of the alewife is 4 to 12 inches; the body is compressed; the head small, with golden gill covers; the eyes large, with silvery iris and black pupil; the mouth very large, the lower jaw slightly the longer, and the upper jaw deeply notched in its centre. The color on the back is bluish purple; the sides are light copper color, beneath silvery; on the sides are 4, 5, or even more indistinct greenish lines passing from the head to the tail; just behind the upper angle of the gill cover is a deep black spot. The scales on the body are very large, and deciduous; the entire abdominal edge is serrated by strong bony spines, largest between the ventrals and the vent; the dorsal fin is single, and the tail is deeply notched. Though thin, dry, and inferior to the herring and the shad, the alewife is a valuable fish. For home consumption, alewives are salted and smoked, like herring. The fishery in the British provinces is valuable.

ALEXANDER. I. A N. W. county of North Carolina, bounded S. by the Catawba river; area, 300 sq. m.; pop. in 1870, 6,868, of whom 611 were colored. The staple products are wheat, corn, and oats. There are 19 churches, and 20 manufactories. Capital, Taylorsville.

II. A S. county of Illinois, at the confluence of the Ohio and Mississippi rivers, the latter forming its S. and S. W. boundary and separating it from Missouri; area, 245 sq. m.; pop. in 1870, 10,564. The face of the county is low and level, and in some parts liable to inundation, and the soil is fertile. The staple products are corn and wheat. The southern terminus of the Illinois Central railroad is at Cairo in this county. Capital, Thebes.

ALEXANDER, surnamed the Great, son of Philip of Macedon and of Olympias of Epirus, born in 356 B. C., died in 323. His first tutor was a Greek, Ly-simachus, and the first thing which he learned was the Iliad. At the age of 13 he received further instruction from Aristotle, and enjoyed this teaching for three years, being then warmly attached to the philosopher. During his father's lifetime he shared in his wars, and in the government of the kingdom, early showing a strong will and an imperious

temper. By his bravery he decided the issue of the battle of Chaeronea (338), which made Philip the master of Greece. He ascended the throne at the age of 20, on the assassination of his father, and put to death several of the guilty, as well as many relations of his father's second wife, and soon afterward Philip's infant son. At the head of an army he at once entered Greece, strengthened the submission of the Greek republics, and at a general Grecian assembly at Corinth was made commander-in-chief, with full powers on land and sea to prosecute the war against Persia. In the following spring (335), in an armed excursion against various tribes of Thracians and others north of Macedonia, he crossed the Danube without a bridge and in the face of an enemy. During this campaign rumors of his death arose in Greece. Demosthenes, in Athens, and the patriots of other Greek cities, and above all the Thebans, considered this to be a propitious moment to emancipate Hellas from Macedonian domination. The Thebans rose in arms. Alexander returned with his army in 13 days from beyond the north of Macedonia to Bœotia. After a murderous assault he razed Thebes to the ground, leaving only the house of Pindar standing, and sparing only the descendants of the poet from slavery or massacre. This blow crushed the aspirations of the Greeks for freedom.—Alexander now completed his preparations for the invasion of Asia. In March or April, 334, he crossed the Hellespont from Sestos to Abydos, with a force of 30,000 foot and 4,500 horse. This army was composed in great part of Macedonians, with Macedonian commanders. At Ilium (Troy) he performed various rites and sacrifices in honor of the ancient heroes, a manifestation of that legendary sympathy which formed the only real relation between him and the Greeks. A Persian army defended the passage of the Granicus. Alexander was the first to enter the river at the head of his troops, fought foremost with great personal courage, and won a decisive victory. Nearly the whole of Asia Minor submitted to him, and the few cities that attempted to resist, among them Halicarnassus, were taken by storm. At Tarsus in Cilicia he was seized with a violent fever, after bathing in the chilly waters of the Cydnus, and owed his recovery to the skill of his physician, Philip. The king of Persia, Darius III., commanding in person an army of five or six hundred thousand men, met him in a valley near Issus, and one of the most important and decisive battles recorded in history was fought there (333). Darius was defeated with immense slaughter, and the loss of his camp and treasures; while his mother, his wife Statira, celebrated as the handsomest woman in Asia, his infant son and two daughters, fell into the hands of the victor, by whom they were treated with unexpected magnanimity. Syria and Phœnicia submitted, with the exception of Tyre, which was taken after an arduous siege of seven months. Alex-

ander was twice obliged to construct a mole more than 200 feet wide across the half-mile channel between the mainland and the islet on which Tyre was situated. At the final storm the carnage was terrible, and 2,000 of the defenders were hung on the walls, 30,000 inhabitants sold into slavery, and the ancient and free-spirited population wholly extirpated.—Alexander now marched toward Egypt. Of the cities of Palestine, only Gaza, commanded by Batis, a eunuch, resisted him. The town had hitherto been thought impregnable, but Alexander surrounded it with artificial mounds equal in elevation to the hill on which the stronghold was situated, and, after having been beaten off in several attacks, in one of which he was severely wounded, took the city, and slaughtered nearly the whole population (332). Batis, covered with wounds, was taken prisoner. The infuriated victor ordered his feet to be bored, and his living body to be attached to a chariot, which he drove himself in full speed through the streets. Thus he copied the ignominious treatment which, according to the legend, was inflicted by Achilles, from whom he claimed descent, on the dead body of Hector. Egypt submitted without offering the slightest resistance. Alexander founded the city of Alexandria, and marched through the desert into Libya to the temple of Jupiter Ammon (331). The priest addressed him as the son of the god, and the conqueror henceforth assumed such to be his parentage, to the great dissatisfaction of his Macedonian army and companions. He was now master of the whole eastern Mediterranean coast, and of all the islands, and returned to Asia in search of Darius, who was lost in the immense dominions which still remained to him. Alexander crossed the Euphrates and Tigris, and in the plains of Gaugamela, near Arbela, in Assyria, reached the Persian army, made up of the contingents from the Caspian sea, the rivers Oxus and Indus, the Persian gulf, and the Red sea. It is said that this army numbered 1,000,000 infantry, 40,000 cavalry, 200 chariots armed with scythes, and 15 elephants, which then made their first appearance on a field of battle beyond their native country. Alexander commanded 40,000 foot and 7,000 horse. The battle was severely contested, but at last the Persians were utterly routed (October, 331). The Persian empire was destroyed. Its two capitals, Babylon and Susa, surrendered, with immense treasures. From Susa Alexander marched into Persia proper, the cradle of the earlier Persian conquerors, overpowering various barbarian mountain tribes on the march. Persepolis and Pasargada fell into his hands, with treasures surpassing those of Babylon and Susa. He set fire to Persepolis; the male inhabitants were slain, and the females dragged into servitude. Next he continued the conquest of the eastern part of the Persian empire, following Darius into Media, Hyrcania, and Parthia, where the fugitive king was murdered by his revolted satraps (330). Alexander

ordered the body to be buried with regal pomp in the royal sepulchres of Persis. Pursuing the satraps, he entered Aria, in the region adjoining the modern Herat. Thence he marched into Drangiana, the modern Sejestan. While at the chief town of this province, on the plea of a conspiracy against his life discovered among those nearest his person, he condemned to death Philotas, one of his first generals, and son of Parmenio, his best captain, and the companion in arms of his father Philip; and after this he ordered the murder of Parmenio himself. He had now become very intemperate, and, full of suspicion, opened the letters of his officers and soldiers to their relations in Europe. He reduced Arachosia and the Paropamisus region (modern Afghanistan), founding various cities of Greeks and Macedonians. Then he overran Bactria (329), crossed the Oxus, marched through Sogdiana, entering the principal city Maracanda, now Samarcand, and reached the river Jaxartes (Sir Daria), which he thought was the Tanais (Don), then considered to be the boundary between Europe and Asia. On its banks he founded a city named Alexandria, as a fortress against the nomadic Scythians, in whose pursuit he reached the present khanate of Khokand. This was the utmost limit of Alexander's northern progress. During his stay at Samarcand, on his return, in a drunken orgy, he killed with his own hand his general and friend Clitus, who had saved his life at the battle of the Granicus, and now ventured to rebuke him for his overbearing pride and infatuated belief in his divine origin. After this bloody deed, the murderer, seized with remorse, passed three days without food and drink. In Bactra (Balkh), the capital of Bactria, he celebrated in 327 an oriental marriage between himself and his captive Roxana, and in the festivities of this ceremony demanded prostration and worship from the Greeks as well as the Asiatics. Some Greek philosophers, Anaxarchus among them, led the way in this degradation; but Callisthenes, the friend and correspondent of Aristotle, opposing it, was falsely accused of a conspiracy, tortured, and put to death. From Bactra Alexander marched southward, recrossing the Paropamisus, or eastern Caucasus, now known as the Hindoo Koosh, and went into Cabool, descending along the right bank of the Indus, and reducing various mountain tribes on the way. He crossed the Indus at or near Attock, a passage now much used, and entered Taxila, whose prince, Taxiles, at once submitted, becoming a tributary ally, and furnishing a contingent to the Macedonian army. On the further side of the Hydaspes (Jhylum, in the Punjab), he met the Indian prince Porus, with a formidable force, which he defeated, taking Porus prisoner. The latter, however, had his possessions restored and became an ally and friend of Alexander. After conquering various Indian princes and nations, Alexander passed the river Acesines (Chenab), and advancing

across the Punjab to the river Hydraotes (Ravee), demolished the city of Sangala, putting to death 17,000 persons, and making 70,000 captives from various free Indian tribes. Thence he marched to the river Hyphasis (Sutlej). Here the Macedonians of the army, averse to plunging further into unknown deserts, refused to cross the river, and Alexander gave the order to return. To mark the limit of his eastward progress, he erected 12 altars of extraordinary height on the W. bank of the Hyphasis. Late in the autumn of 327 he embarked with a part of his army on the Hydaspes, and sailed down to the Indus, which he descended to its mouth, disembarking perpetually to attack, subdue, and slaughter the tribes near the shore. He reached the Indian ocean in the summer of 326. Nearchus, his admiral, took the fleet from the mouth of the Indus round the Persian gulf to the Tigris, while Alexander himself marched westward along the shores of the gulf, then through the desert of Gedrosia (Beloochistan) to the city of Pura (Balnpoora). In this march the soldiers suffered much from thirst and hunger. To compensate for this, and in imitation of the festivals of Bacchus, Alexander and his army marched seven days in drunken bacchanalian procession through Carmania (Kerman), entering Persis, and finally, in the beginning of 325, reaching Susa. Here he adopted the Persian costume and ceremonial, made a eunuch, Bagoas, his favorite, and contracted two additional Asiatic marriages. He sailed down the river Pasitigris (Karun) to the Persian gulf, and, anxious for naval glory, projected the circumnavigation and conquest of Arabia. An immense fleet was built in the Phœnician ports, taken to pieces, and conveyed to Babylon, which was transformed into a harbor for the purpose. At this time he received embassies from all the nations around the Mediterranean, including the Romans, Iberians, and Gauls. Having entered Babylon in 324, he spent several days in surveying the surrounding marshes, where he contracted the germs of a violent fever. This malady was developed and heightened by his daily revelries, and finally put an end to his life after a reign of 12 years and 8 months. He appointed no successor, but before his death gave his ring to Perdicas. Shortly afterward Roxana gave birth to a son, Alexander Ægus, who was put to death with his mother by Cassander in 311, while the conqueror's great empire was divided by his generals.—Alexander's reign forms one of the pivots of the world's history. By it Asia and the East were interwoven with Europe and Greece, while the free Greek communities were crushed and democratic progress and liberty entombed. His generalship, his knowledge of command, his strategic combinations, his far-reaching plans, his foresight and fertility in difficulties, his rapidity of movement, are almost without a parallel in history, when we consider the time, the regions where he acted, and the

resources at his disposal. With all his courage and his sanguine temperament, nothing was ever omitted in the way of systematic military precaution. Nor is his life devoid of other traits of greatness. The acquisition of universal dominion was the master passion of his soul. He had no attachment for any special nationality, but looked on all mankind as on a realm to be conquered and ruled. His conquests caused an immense diffusion of Hellenic culture, and influenced for ages the condition of western Asia and of Egypt.

ALEXANDER, the name of eight popes. **I. Saint**, a Roman by birth, according to ecclesiastical tradition, governed the church from 108 to 119, and was beheaded by order of the emperor Hadrian. A beautiful church has been erected over his tomb. **II. Anselmo Badagio**, born in Milan, was bishop of Lucca, became pope through the influence of Hildebrand (afterward Gregory VII.), and reigned from 1061 to 1073. The first few years of his reign were troubled by a contest with an anti-pope named Cadalöus, who took the name of Honorius II. He carried out with great vigor and ability the measures of the reforming party in the church of which Hildebrand was the life and soul, against simony and concubinage among the clergy, and the intrusion of unworthy bishops into the episcopal sees through the influence of princes and nobles. By the advice of Hildebrand, he pronounced in favor of the claims of William of Normandy to the crown of England, as successor to Edward the Confessor. After the success of William's arms, in 1066, he sent as legate into England Bishop Ermenfroi, and the cardinals Peter and John, who crowned King William, and afterward held a council at Winchester, in which Stigand, the excommunicated archbishop of Canterbury, who had intruded himself into that see during the lifetime of the archbishop Robert, was deposed. The celebrated Lanfranc, formerly the preceptor of Alexander, was placed in that see, and afterward received by the pope with great honor at Rome. Alexander maintained close relations with the Byzantine empire, and sent a legate to the Greek court. A number of his epistles are extant, among which is one addressed to the bishops of France, in which he condemns in the strongest terms the cruelties practised by some Christians on the Jews. **III. Rolando Bandinelli**, born in Siena, elected Sept. 7, 1159, died Aug. 1, 1181. He had to sustain a long conflict with Frederick Barbarossa and four successive anti-popes, one of whom, styling himself Calixtus III., came to him at Frascati in 1178, threw himself at his feet, and demanded absolution, which Pope Alexander granted immediately, inviting him to his own table. The emperor, who had been excommunicated, submitted after a protracted struggle in 1177, and was absolved from his excommunication at Venice. On this occasion he paid the ordinary homage to the pope by kissing his foot, and leading the mule on which he rode; but the story that the pope put

his foot on his neck appears to rest on no historical foundation. Alexander entered into correspondence with the Greek emperor Manuel, with the view of inducing him to consent to a project, much favored at that time in Italy, of transferring the imperial throne to Rome, and thus effecting a permanent reconciliation of the Greeks to the Roman church. These negotiations, however, had no result. He also held at Tours in France, where he had taken refuge in the early part of his pontificate, a council against the Albigenses. Supported by him, Thomas à Becket carried on the ecclesiastical struggle with King Henry II. of England. à Becket and St. Bernard were canonized by Alexander III., a right which he first reserved exclusively to the holy see by a decree promulgated at the council of Tours. It was this pope who instituted the ceremony of the espousal of the Adriatic by the doge of Venice. The last remarkable act of his life was the celebration of the third general council of Lateran at Rome, in 1179. **IV. Rinaldo di Segni**, a Roman, nephew of Gregory IX., and cardinal bishop of Ostia, elected at Naples, Dec. 12, 1254, died at Viterbo, May 25, 1261. During his reign the states of the church were devastated by Manfred, the natural son of the emperor Frederick II. He declared a crusade against Manfred, which proved unsuccessful, even with the aid of Henry III. of England, to whose second son Edmund he gave, in quality of suzerain, the investiture of the kingdom of Sicily. During his reign occurred also the crusade and captivity of St. Louis of France. By request of this prince, the inquisition was established in France in 1255. This pontiff was compelled to pass the latter part of his life at Viterbo, on account of seditions among the Roman populace. He labored to reunite the Greek to the Roman church, and to combine the Christian nations against the Moslems. The hostility of the Venetians and Genoese prevented the success of his plans, and the chagrin which he experienced in consequence is said to have caused his death. **V. Pietro Filargo**, born in Candia, elected by the general council of Pisa, June 26, 1409, died May 3, 1410. He was originally a beggar, and was educated by a charitable Franciscan, and sent to Oxford and Paris, where he greatly distinguished himself. On his return he became private tutor to the duke of Milan, and afterward archbishop of that city. Innocent VII. made him cardinal and papal legate in Lombardy. After his elevation to the pontificate, he resided at Bologna. **VI. Rodrigo Lenzaolo**, or **Borgia**, born in Valencia, Spain, in 1431, elected pope Aug. 11, 1492, died Aug. 18, 1503. His mother was a Borgia and the sister of Pope Calixtus III. His father was an officer of rank, and Rodrigo passed his youth first in the study of law and in civil offices, and afterward in the profession of arms, for which he displayed considerable talent. He formed a criminal relation with a widow, and after her death took for his mistress her daughter, Rosa

Vanozza, by whom he had five children, one of whom was Caesar Borgia, and another Lucretia, afterward duchess of Este. When his uncle became pope, Rodrigo was summoned to Rome. He went with reluctance; but whatever unwillingness he may have felt to abandon his pleasures in Spain was overcome by the generosity of the pontiff, who hastened to appoint him archbishop of Valencia, cardinal deacon, and vice chancellor of the church, and gave him a revenue of 28,000 crowns a year. Without breaking off his connection with Vanozza, he now assumed an exterior of piety and humility, visited the hospitals, gave much to the poor, and acquired a reputation for extraordinary virtue. Under Popes Pius II. and Paul II., who wore the tiara after Calixtus, little is known of his life. He was high in the favor of Sixtus IV., who sent him as legate to Aragon and Portugal; but he is said to have caused some scandal at the court of Lisbon by his licentious behavior. After the accession of Innocent VIII. (1484) he brought his mistress secretly to Rome, and furnished her with an ostensible husband, in the person of a Spaniard who had been her majordomo. Under the protection of this pseudo count, the cardinal was enabled to visit Vanozza without suspicion. On the death of Innocent in 1492 he bought the suffrages of the adherents of Cardinals Sforza, Orsino, Riario, and Colonna, and, having been thereupon elected to the pontificate, delivered an edifying discourse in which he urged the sacred college to reform their lives, and denounced with especial severity the crimes of avarice and simony. His eldest son, Francesco, was appointed commander of the papal troops; his second son, Caesar, was made archbishop of Valencia, and a year later cardinal. The Papal States were at this time in a very disturbed condition, and Alexander's first care was to strengthen the temporal power by crushing the turbulent lords of Ferrara, Bologna, Rimini, Faenza, Ostia, and Urbino, forming a league against Naples with Venice and Milan, and then a league with Naples against France. Unable to prevent the invasion of Italy by Charles VIII., he made his peace with the French king at an interview in the Vatican; and after Charles had taken possession of Naples he instigated a new confederation against him, composed of the republic of Venice, the duke of Milan, and the other princes of Italy, and succeeded at last in ridding the peninsula of the invaders. He allied himself with Charles's successor, Louis XII., in an attack upon Milan, granted the king a divorce, and obtained for his son Caesar a splendid position at the French court. He was a party to the treachery by which Ferdinand of Spain first betrayed the cause of his relative Frederick of Naples by partitioning that kingdom between Louis XII. and himself, and then betrayed Louis by seizing the whole conquest. Caesar had accompanied the French to Milan, and thence waged incessant war upon the Italian

princes, the pope's purpose being not only to consolidate his own temporal power, but to elevate his family to the dignities of the dispossessed barons. Vile as the means were by which he accumulated wealth, he spent it in such a way within his dominions, restoring order and reviving trade, that he was popular with his subjects. He carried simony to a point never before dreamed of, and a contemporary pasquinade began with the lines,

Vendit Alexander claves, altaria, Christum;
Vendere jure potest, emerat ille prius.

The crimes of wholesale poisoning and other murders commonly laid to his charge are not all supported by sufficient evidence, but enough is known to entitle him to remembrance as the worst of all the popes. His death is said by some historians to have been caused by poison which he intended for a large party of cardinals whom he had invited to a banquet. **VII. Fabio Chigi**, born of an illustrious family at Siena, Feb. 13, 1599, elected April 7, 1655, died May 22, 1667. Before his election he filled several of the highest offices of the Roman church with credit. During his pontificate he was zealous in the reformation of discipline. He confirmed the bull of Innocent X. against the five propositions of Jansenius, and prescribed a formulary condemning the principles of Jansenism, which all persons concerned were required to sign. He finished the college of Sapienza, commenced by Leo X. after designs of Michel Angelo, and constructed the beautiful colonnade in the piazza of St. Peter's. **VIII. Marco Ottoboni**, son of the grand chancellor of Venice, where he was born, April 19, 1610, elected Oct. 6, 1689, died Feb. 1, 1691. He studied at Padua and Rome, was successively bishop of Brescia and Frascati, and cardinal. He condemned the four articles of the Gallican assembly, and assisted the emperor Leopold I. and the Venetians with large sums in the wars against the Turks. He possessed a high degree of prudence, moderation, and political sagacity, and was very benevolent to the poor, but too much inclined to favor his own relations.

ALEXANDER I., Pavlovitch, emperor of Russia, eldest son of Paul I. and Maria Feodorovna, princess of Württemberg, born Dec. 23, 1777, died Dec. 1, 1825. His grandmother, Catharine II., designed to place him on the throne in preference to his father, and intrusted the care of his education to Count Nicholas Soltikoff, drawing up the plan of his instruction with her own hand. Every possible branch was taught except music and singing. In 1783 Count Soltikoff selected as his tutor Frédéric César de la Harpe, who inculcated in the mind of his pupil the ruling liberal ideas of the 18th century. Toleration, philanthropy, and love of truth were from his childhood familiar to the future czar. Sometimes he dreaded the task before him, and wished to escape with his youthful friend Prince Czartoryski to America, and to live there as a private citizen. At the age of

15 he was married to Louisa Maria Augusta, princess of Baden, who was somewhat younger still. This marriage was not a happy one. Catharine died three years afterward, and was succeeded by her son Paul I., whose short reign was ended by murder, March 23, 1801. Alexander stands accused of having been accessory to this crime. He was acquainted with the conspiracy, whose chief, Count Pahlen, persuaded him that his mother and his brother Constantine were in danger of losing their liberty, and even their lives, from the jealous suspicions of his half-insane father. Alexander, fully believing his father incompetent to reign, gave his consent to the dethronement, which alone was represented to be the aim of the conspirators. Once on the throne, the young czar attracted the attention of the world, and his generous qualities promised a brilliant future. He began by releasing and indemnifying the victims of the violent injustice of his father, and recalled many who had been exiled to Siberia. He kindled civilization among the masses, made efforts to create a public spirit among the people, and accomplished radical reforms in the administration. He abolished the secret tribunal established by Paul, suppressed the censorship, reorganized the board constituted by Catharine for the creation of a national code, ordered every minister to publish yearly reports, decreed the abolition of torture (which, however, continued to be partially applied even under him), and renewed the ukases of Catharine in virtue of which hereditary estates could not be confiscated, and proclaimed that henceforth the czars should not give away estates with crown peasants, but lands alone. He prohibited the public exposure of serfs in markets for sale, and allowed them to be sold only with the land to which they were attached. He chose for ministers men of large and clear minds, devoted to his reformatory ideas. Among these were Czartoryski, Novosiltzoff, and Speranski. He was impressive, enthusiastic, and easily influenced, not steady and persistent. His mode of life was simple and unostentatious; his manners were amiable, refined, and elegant. He concluded commercial treaties with various powers, and published new regulations for navigation. He protected the arts, and in order to stir up the intellectual powers of the people allowed his subjects of various classes, except those serfs who were private property, to select their own trades and pursuits. The raw products of Russia, and even some manufactures, now began to appear in the marts of Europe. In 1809 he erected three universities, at St. Petersburg, Kharkov, and Kazan, and added to them afterward that of Dorpat for the German Baltic provinces. He also reorganized that of Wilna for his Polish subjects, whom at that early epoch he treated generously, flattering them with hopes of the reconstruction of their kingdom. He founded many gymnasia and high schools, ordering their

number to be increased to 204, with 2,000 subordinate elementary schools; but this project was only partially executed. He was wont to travel over the country in every direction, seeing persons of all classes and receiving their memorials. He scrupulously observed the ordinances of the national church, but later in life he became a pietist and mystic, at the same time that he turned against the liberal politics of his youth.—At an early period in his career Alexander was entangled in the great events which shook Europe in the beginning of the present century. The greatness of Napoleon, then first consul, impressed his imagination. His father had commenced a friendly intercourse with Napoleon, which the son continued. On Oct. 8, 1801, he concluded a treaty of friendship, and when next year a general peace was established by the treaty of Amiens, the new territorial organization of Germany was regulated by the two. But when Napoleon, after making himself emperor, violated the territory of Baden, announced his purpose to assume the crown of Italy, prepared to destroy the independence of the Batavian republic, and occupied almost the whole coast of northern Germany, Alexander put forth a solemn protest along with a warning against a continuance in this course of usurpation. Finally, although a war was brewing between Russia and Turkey, and another actually waging against Persia, Alexander entered the third coalition to overthrow Napoleon formed by Sweden, England, and Austria. On Oct. 5, 1805, a Russian army debarked in Pomerania, and at the same time another traversed Prussia, although that power was neutral. The battle of Austerlitz, Dec. 2, 1805, destroyed the coalition, and Alexander barely escaped being made prisoner by a French general cutting off the retreat of his escort. The czar pledged his written word of honor to this officer that an armistice had been concluded, which, however, was not the case. The Russian troops retreated to Silesia, and Alexander returned to St. Petersburg to prepare new armaments, when his ally Francis of Austria made peace with the enemy. The czar, however, refused to ratify the treaty made in Paris by his minister D'Oubril, and formed an intimate alliance with Prussia. He conceived a Platonic affection for Queen Louise, to whose husband, Frederick William III., he was bound by the ties of a strong friendship. This new coalition had no better luck than its predecessor. The Prussian forces were annihilated at Jena and Auerstädt (Oct. 14, 1806), the Russian Marshal Benningsen was beaten at Eylau (Feb. 8, 1807) and Friedland (June 14), and Kamenski was defeated at Pultusk. The Russian armies reentered their own country, and the king of Prussia was left in possession of only the city of Memel, on the Russian frontier. At the same time, however, the Russian arms were more successful in the war with the Turks. The Serbs rose against the Porte, and Admiral Seniavin

beat the Turkish fleet in the Archipelago. Prussia being annihilated, and Napoleon at the threshold of Russia, Alexander was forced to negotiate. In June, 1807, the two emperors met on a raft on the river Niemen, the frontier between Prussia and Russia. In the course of their now almost daily intercourse, Napoleon not only bewitched Alexander by his genius and his manners, but did not disdain to flatter the foibles of the czar, whose former resentment gave way to the most enthusiastic friendship and admiration. By the treaty of Tilsit, Alexander got from the Prussian spoils the district of Bialystok in Lithuania. He entered warmly into all the Napoleonic schemes, and accepted the continental system, though it was pernicious at the start to the agricultural interests and the exporting trade of Russia. Gustavus IV. having rejected every plan of accommodation with France, and refused the invitation of Russia to exclude English vessels from Swedish harbors, Alexander declared war against Sweden, invaded Finland, and conquered the long-coveted duchy. The war was not yet ended when the interview of Erfurt took place, beginning Sept. 27, 1808. Here culminated the friendship of the two emperors, who, representing the west and the east, decided the destinies of Europe. The resistance of the Spaniards to Joseph Bonaparte, and English subsidies, encouraged the court of Vienna to appeal to arms for the third time in 1809. Alexander, as the ally of Napoleon, occupied Galicia, and at the peace got a slice of it. In Turkey, the fortresses of Rustchuk, Giurgevo, and Silistria were taken, and the bulk of the Turkish army on the left side of the Danube laid down their arms before Kutuzoff. The war with Persia was also successful. In the interior Alexander continued the work of reform. The exclusion of English manufactures gave activity to domestic industry. In 1810 he reorganized the council of the empire, and formed eight separate departments or ministries. He regulated the value of the currency, introduced a new organization into Finland, and in 1811 inaugurated the church of the Holy Virgin of Kazan, one of the great monuments of St. Petersburg. About this epoch a revolution took place in his feelings toward Napoleon, and he inclined to the ancient party of his nobles, who were enemies of France and of domestic reforms, and partisans of England. Under this influence he exiled some of his former favorites, who for years had labored with him in the task of reform. Napoleon now occupied the duchy of Oldenburg, and Alexander refused him his sister in marriage. The immense majority of the Russian nobility were hostile to the French alliance. Animosity increased, and the war of 1812 broke out. England and Sweden alone stood by Russia—at that time helpless and negative allies; but the treaty of Bucharest, concluded in that year by the mediation of England, on terms wholly advantageous to Russia, disengaged the Russian

armies operating on the Pruth and the Danul e. Napoleon rapidly crossed the Niemen and invaded Russia, directing one part of his forces north toward St. Petersburg, while he himself pressed with the mass upon the centre of the empire toward Moscow. Alexander was taken almost unawares. He adopted the plan of Gen. Barclay de Tolly, retiring slowly step by step, to draw the enemy into the interior, destroying everything in the retreat, and thus facilitating the union of the central army with that coming from Turkey. He made an appeal to the religious and national feelings of the Russians, and organized levies *en masse*. The people were even more excited than their ruler. After the battle of Smolensk (Aug. 17) he transferred the command of the retreating but not dispirited army to Kutuzoff, yielding to the desire of the nation to be commanded by a native Russian. It is not ascertained whether he ordered the burning of Moscow, but at any rate he approved the act. He refused all accommodation with Napoleon, answering that he had only begun the campaign, and would not treat while a foot of his dominions was occupied by the enemy. The retreat of the French, the terrible crossing of the Beresina, and the final annihilation of the invaders, are well known. The Russian forces now overran the duchy of Warsaw, which had been created by the treaty of Tilsit, and whose free institutions had caused much uneasiness in Russia; and soon afterward it was definitely incorporated with the empire. The advisers of Alexander—Kutuzoff, Volkonski, Arakcheyeff, Balashoff—insisted on arresting there the further pursuit of the French, and leaving the rest of Europe to its fate. But England urged the continuation of the war, Prussia asked for help, and Alexander, in his manifestoes from Warsaw, Feb. 22, and Kalisz, March 25, 1813, appealed to the European nations as the redeemer of the continent. In Kalisz an offensive treaty against Napoleon was concluded between Russia, Prussia, and England, at the same time that the czar, animated with new impulses of religion, founded a Bible society, to spread the gospel among all nations. He took part personally in various battles in Germany and France, where he arrived as the leader of the crusade against Napoleon. On Oct. 12, 1813, the treaty of Gullistan put an end to the war with Persia, and Russia acquired thereby a part of the Caucasus and of Armenia. In Paris, Alexander defended the integrity of France against others of the allies. In June, 1814, he visited London, where he was brilliantly received. In July of the same year he made a short visit to St. Petersburg. The senate proffered to him the title of "God-sent," which he refused. At the congress of Vienna, of which he was the most influential member, he gave to his newly conquered subjects, the Poles, a constitution, of which Carnot said that it was too good to be observed.— Napoleon's escape from Elba now shook Eu-

rope anew. On March 13, 1815, Alexander signed the proclamation by which the great soldier was outlawed. Waterloo soon followed, and for the second time Alexander entered Paris victoriously, July 11, 1815. His religious excitement now increased, and with it his indifference first, and then his hostility to liberty. In Paris, in 1815, under the inspirations of the celebrated Mme. Krüdener, he formed the holy alliance, which was to base the political order of the world on the principles of Christianity, or, as it came to be understood, of despotism. The czar now took the lead in European affairs. In Russia trade and industry revived, and efforts were made to expand the national resources. Alexander was inspired with the best intentions, but lacked the energy to carry them out. He began a partial abolition of serfdom by emancipating the serfs in the German Baltic provinces, but without allowing the peasantry the liberty of migrating from one province to another. In 1818 he virtually presided at the congress of Aix-la-Chapelle, and from that epoch may be dated the complete abandonment of his once cherished liberal and reformatory ideas. Exhausted bodily by various excesses, and mentally by the pressure of the terrible events in which for more than ten years he had played a part requiring almost superhuman efforts, he became the leader of the reaction against all free tendencies. Metternich adroitly played upon his fears, and he almost wholly abandoned to his ministers the internal administration of Russia, while he devoted himself to suppressing liberal movements in Italy, Spain, Portugal, and Germany. At the congresses of Troppau (1820), Laybach (1821), and Verona (1822), he urgently sustained this policy. The constitution of Poland had been violated in its principal parts. Irritation increased between the nation and the sovereign; conspiracies were formed in connection with the Carbonarism then existing in France and the south of Europe. At the same time new ideas were brought to Russia by the armies returning from the west, especially by those which had occupied France for several years. The political institutions and social state of other nations thus becoming better known, the desire spread rapidly for changes more in harmony with the spirit of the age. Discontent was increased by the absence of administrative ability and integrity. The army was disorganized. In imitation of Austria, and with the view of surrounding St. Petersburg with an immense military force, military colonies of the peasantry were created by Arakcheyeff, now the virtual ruler of the country. The censorship of the press was exceedingly severe. Alexander became more and more the prey of hypochondria, gloomy, distrustful, inaccessible. The man who once received with a smile the memorials presented by his subjects, now ordered that any one who approached him in public should be arrested and kept 24 hours in prison. Once an active freemason, he now

suppressed the lodges throughout the empire. The secret police, whose operations embraced not only Russia but all Europe, became more active than ever, the grand duke Constantine, brother of the czar, being at its head. The Jesuits, who, even after their suppression in the 18th century all over the world, had been tolerated in Lithuania and Russia, were expelled in 1821 and 1822, for spreading Roman Catholicism among wealthy Russian families, and their establishment at St. Petersburg was handed over to the Dominicans. Alexander estranged himself from many who had once been his friends. Only Volkonski, a thorough absolutist, but otherwise noble-minded, and Arakcheyeff, a despot by nature, remained unshaken in his favor. Arakcheyeff, indeed, had been the favorite of Paul, and Alexander retained him near his person during his whole reign, as if to atone for his father's murder. Joseph de Maistre, the philosopher of absolutism, then residing at St. Petersburg, said of the czar after an interview that despotism was breathed out of his nostrils. Alexander accused his people, the Poles, and all Europe indeed, of ingratitude. He hated every spot in turn, quitting St. Petersburg and Russia to visit foreign countries, and returning equally dissatisfied. Finally the outbreak in Greece fearfully increased the dissidence between the czar and the nation. The feeling and sympathies of the people were with the insurgents. For more than half a century the whole influence of Russia had been employed to stir up the Greeks. Now, when the moment of action came, Alexander, under the advice of Metternich and Nesselrode, opposed the natural policy of Russia, abandoned the Greeks to their fate, and suffered one of their leaders, Alexander Ypsilanti, once his favorite aide-de-camp and confidant, to pine in Austrian dungeons. The marriage of the czar being childless, he had become fondly attached to a natural daughter by Mme. Naryshkin. The death of this girl, coupled with a fearful inundation at St. Petersburg in 1824, destroyed his mental equilibrium. These catastrophes he considered as the punishment of parricide. In September, 1825, in compliance with the order of his physicians, he went with his wife on a journey to southern Russia. Arriving at Taganrog, he left the empress and continued his excursion into the Crimea. Attacked by the Crimean fever, combined with erysipelas, he returned to Taganrog, where he died. A few weeks before his death Count Witt, one of the chief authorities of the military colonies in the south of Russia, disclosed to him the existence of a wide-spread conspiracy against the imperial family. He, however, was unmoved by the information, and his successor, his brother Nicholas, had to fight his way to the throne.

ALEXANDER II., Nicolaeivitch, emperor of Russia, son of the czar Nicholas and Alexandra Feodorovna (originally Charlotte), a sister of Frederick William IV. and William I.

of Prussia, born April 29, 1818. From the cradle he was the object of the most tender love of both his parents. His education was exceedingly careful. His father directed it, and gave almost daily attention to its progress. Gen. Frederies, and afterward Gen. Kavelin, were his immediate tutors. Contrary to the previous usage with Russian imperial princes, his uncle Alexander I. and his father were educated by foreigners. Alexander II. received instruction mainly from native Russians, among whom Zhukovsky, one of the greatest Russian poets, filled the chief place. Without transcendent abilities, Alexander learned well everything taught him. His judgment and perception were clear, and he seldom showed those outbreaks of violent passion which had always been prominent characteristics of the Romanoffs. This gentleness of character he inherited from his mother. Early in youth he showed a love of justice and forbearance, often trying to assuage the feelings which had been wounded by the asperity of his father. Before seeing foreign countries, according to the wish of Nicholas, he travelled all over Russia. When he approached manhood, the prince de Lieven, formerly Russian ambassador in London, was made his tutor, principally to acquaint him with the diplomacy of Europe, its routine and etiquette, and to accompany him in his travels in England, Germany, and Italy. His father's antipathy to Louis Philippe, however, prevented him from visiting France during the reign of that king. On April 28, 1841, he married Maria Alexandrovna, daughter of the grand duke of Hesse-Darmstadt, born in 1824. It was wholly a love match, the young prince having made his own choice among a host of German princesses. His majority was declared on May 8, 1844, and from the age of 18 he was admitted by his father to study the difficult task of governing the empire, by attendance at all the sittings of ministers with the emperor; and when in 1846 Nicholas resided for several months in Italy, he delegated to his son all his vast powers. Indeed, to the end of his father's life the relations of the two were most confidential and affectionate. On March 2, 1855, he mounted the throne, at a most critical moment for Russia. Nicholas had left the country engaged single-handed in a war against England, France, Turkey, and Sardinia, with Austria as a passive enemy. For a year Alexander unflinchingly continued the strife. Sebastopol was taken in September, 1855; but the allies won nothing more, and the Russian resistance continued. During the ensuing winter the neutral German states, especially Prussia and Saxony, finding Louis Napoleon not averse to peace, offered mediation. An armistice was agreed upon in March, 1856, a conference convoked at Paris, and a final treaty concluded there on the 30th of that month. On Sept. 7, 1856, Alexander was solemnly crowned at Moscow. Since then he has relaxed the lines drawn to the utmost ten-

sion by his predecessor. He began with emancipating the nation from the military routine which permeated every branch of the administration. He reorganized the army, dissolved the greater part of the military colonies, freed public instruction from military discipline, and, instead of placing discharged officers as tutors and professors at the head of the educational establishments, appointed men fitted by special studies for these positions. The censorship was considerably relaxed and limited, and for the first time genuine publicity was introduced into Russia. He prohibited espionage, and instituted measures against official corruption, allowing it to be ferreted out and exposed. He advanced young men in the different branches of the public service, superseding those whose only merit was long routine. He gave a new impulse to internal industry and trade, at the same time that he sought to develop the national commercial marine, and to induce native merchants to extend their relations with foreign countries. He annulled the impediments which prevented Russians from visiting foreign lands; granted a general amnesty for political offenders, Poles and Russians, recalling the exiles from Siberia, and allowing fugitives to return; and inaugurated that vast system of internal communication which is to cover his immense empire with nets of railroads. His greatest measure of reform, however, is the emancipation of the serfs. He had conceived from his earliest youth the idea of this measure, and was assisted by Nicholas Milutin and Gen. Bostoffzoff in the preliminary steps. He silenced the opposition of the serf-owners by intimating to them that if there was to be revolution, it had better begin at the summit than at the bottom of society. Their emancipation was decreed March 3, 1861, and carried out within the following two years. His reformatory activity, however, was interrupted, and to a degree checked, by the Polish insurrection of January, 1863, which was finally crushed in the spring of 1864, and punished by the most rigorous measures against Polish nationality, followed by restrictions of a milder kind imposed upon other non-Russian provinces of the empire. In 1865 the czar rejected the demand of the old Moscow nobility for a representative government. An attempt upon his life, April 16, 1866, by Dimitri Karakozoff, was frustrated by the interposition of the peasant Komisaroff, who was ennobled as a reward for his action. A second attempt upon his life was made at the Paris exhibition of 1867, by Berezowski, a Pole. The work of reform was resumed in 1870, when the surprising successes of the Germans startled the Russian nation. The hereditary character of the priesthood was abolished, the army system was reorganized on the Prussian model, and vast measures for education were inaugurated. While persevering in his steady progress of annexation in central Asia, the czar in 1867 divested him-

self of his foothold on the American continent by the sale of Alaska. During the Franco-German war he secured at the London conference of 1870, by a modification of the treaty of Paris of 1856, the deneutralization of the Black sea.—ALEXANDER ALEXANDROVITCH, son of the preceding, and, since the death of his elder brother Nicholas in 1865, czarévitch or heir apparent to the throne, was born March 19, 1845. In 1866 he married the Danish princess Dagmar, who had been engaged to his elder brother. Their eldest child, NICHOLAS ALEXANDROVITCH, was born May 18, 1868. The czarévitch is noted for his sympathies with the old Russian party, who are prejudiced against the Germans, and against all foreigners. His younger brother, the grand duke Alexis, visited the United States in 1871-2.

ALEXANDER, the name of three kings of Scotland. **I.** Succeeded his brother Edgar, Jan. 8, 1107, and died April 27, 1124. He was a prince of singular energy and capacity, which stood him in good stead during the rebellions that disturbed his reign, all of which he suppressed. He secured the independence of the Scottish hierarchy, opposed the pretensions of the English bishops, and cultivated letters. **II.** Succeeded his father, William the Lion, Dec. 4, 1214, and died July 8, 1249. He stands conspicuous among Scottish kings for administrative ability and equity. He united with the league of English barons against King John, and was consequently for two years under excommunication. On the accession of Henry III., Alexander ratified a peace with England by marrying Henry's sister, after whose death without issue Henry invaded Scotland; but the Scottish barons rallied in such force to the support of their king that the war was concluded without a battle. **III.** Son of the preceding by his second wife, a French lady, succeeded his father at the age of 8, married the daughter of Henry III. at the age of 10, and died March 16, 1286. He defeated the attempts of Henry to obtain a controlling influence in Scottish affairs, repelled an invasion of Haaco, king of Norway (1263), securing as a consequence the allegiance of the Hebrides and the Isle of Man, and brought about a marriage between his daughter Margaret and the Norwegian king Eric (1282). Margaret died the next year, leaving a daughter Margaret, called the Maiden of Norway, whose death on the way to take possession of her throne was the cause of great misfortunes to Scotland.

ALEXANDER, Alexander Humphreys, a claimant of the earldom of Stirling, born in Birmingham, England, about 1783. In 1824 he obtained the royal license to assume the name of Alexander, on the ground that he had a maternal grandfather of that name, that his deceased mother was a great-great-granddaughter of the Hon. John Alexander, fourth son of the last earl of Stirling (see ALEXANDER, WILLIAM), and that, all intermediate heirs being extinct, he was sole

heir to the honors and property of the earldom and charter. For a short time he succeeded in exercising the privileges of earl without undergoing any legal investigation of his claims, and he even claimed from the crown a vast territory in Nova Scotia, which he declared had been granted to the earls of Stirling. He raised large sums on these pretensions, and assumed various rights in connection with them; but at last his claims were challenged by the crown lawyers of Scotland in 1839, and a trial ensued, in which Humphreys (Alexander) brought forward to prove his pedigree several documents purporting to be old manuscripts brought to light in various mysterious ways. These were, however, proved to be forgeries; and his pretensions being thus brought to an end, he withdrew into obscurity.

ALEXANDER, Archibald, D. D., an American Presbyterian divine, born in Augusta county (now Rockbridge), Va., April 17, 1772, died in Princeton, N. J., Oct. 22, 1851. His grandfather, Archibald Alexander, was of Scotch descent, though an emigrant from Ireland, whence he came to Pennsylvania in 1736, and, after a residence there of about two years, removed to Virginia. His son William, the father of the subject of this sketch, was a farmer and trader. At the age of 10 years Archibald was sent to the academy of the Rev. William Graham, at Timber Ridge meeting house, and at the age of 17 he became tutor in the family of Gen. John Posey, of the Wilderness, twelve miles west of Fredericksburg. He remained there but one year, and in 1789 he returned home and resumed his studies with Mr. Graham. At this time his mind became influenced by the remarkable religious movement which is yet spoken of as "the great revival," and he turned his attention to divinity. He was licensed at Winchester, Oct. 1, 1791, and spent some years in itinerant missionary service in different parts of his native state. In 1789 he succeeded Dr. John Blair Smith as president of Hampden Sidney college, but in 1801 resigned, and made a journey to New York and New England. While on his way to the north he visited the Rev. Dr. Waddel, the celebrated "blind preacher" mentioned by Mr. Wirt in the "British Spy," and contracted a matrimonial engagement with his daughter, Janetta, whom he married on his return in 1802. He then resumed his former position at Hampden Sidney college, but owing to insubordination among the students he accepted a call from the Pine street church in Philadelphia, where he was installed pastor May 30, 1807. The degree of D. D. was conferred upon him by the college of New Jersey in 1810, and in the same year he was elected president of Union college in Georgia, a fact which remained unknown even by his family until after his death. The theological seminary at Princeton was established by the general assembly of the Presbyterian church in 1811, and Dr. Alexander was by common consent elected as its first theologi-

cal professor, which position he sustained until his death. He published "Outlines of the Evidences of Christianity," which has passed through numerous editions in various languages, and is recognized as a text book in several colleges; "Treatise on the Canon of the Old and New Testament" (1826); "History of the Patriarchs" (1833); "Essays on Religious Experience" (1840); "History of African Colonization" (1846); "History of the Log College" (1846); and a "History of the Israelitish Nation" (1852). His work on "Moral Science" was published after his death; and among his unfinished works are one on the "Duties and Consolations of the Christian"; one on "Patriarchal Theology"; a memoir of his old instructor, Mr. Graham; a history of the Presbyterian church in Virginia; biographical sketches of distinguished American clergymen and alumni of the college of New Jersey; and a work on "Church Polity and Discipline."

ALEXANDER, Sir James Edward, a British soldier and writer, born in Scotland in 1803. He is descended from the Stirling family, studied at Sandhurst, served in the Burman war (1825), in the Russian service against Turkey (1829), in Dom Pedro's cause in Portugal (1834), in quelling the disturbances in Canada (1839), in the Crimean war, after the close of which he became colonel (1858), and in the Maori war in New Zealand (1863). He has published "Travels from India to England" (London, 1827); "Expedition of Discovery into the Interior of Africa" (1838), undertaken while stationed at Cape Town; "Passages in the Life of a Soldier" (1857); and "Incidents of the late Maori War" (1863).

ALEXANDER, James Waddel, D. D., eldest son of Dr. Archibald Alexander, born in Louisa county, Va., March 13, 1804, died at the Red Sweet Springs, Va., July 31, 1859. He graduated at the college of New Jersey in 1820, was appointed a tutor there in 1824, resigned in the following year, was settled as pastor of a congregation in Charlotte county, Va., and in 1828 accepted a call to Trenton, N. J. In 1830 he resigned that charge and became editor of "The Presbyterian," a religious newspaper published in Philadelphia, whence he was called in 1833 to the professorship of rhetoric and belles-lettres in the college of New Jersey. In 1844 he accepted the pastoral charge of the Duane street church in New York. In 1849 he was appointed professor of ecclesiastical history and church government in the theological seminary at Princeton, where he remained till 1851, when he was chosen pastor of the Fifth avenue church in New York, which station he held till his death. His published works include "Consolation, in Discourses on Select Topics, addressed to the Suffering People of God"; "Thoughts on Family Worship"; "Plain Words to a Young Communicant"; "Thoughts on Preaching"; a series of essays entitled "The American Mechanic and Workingman"; "Discourses on Christian Faith and Practice";

a biography of Dr. Archibald Alexander; and numerous contributions to the "Biblical Repository" and "Princeton Review," as well as to the publications of the American tract society. The Rev. John Hall, D. D., edited in 1860 "Forty Years' Familiar Letters of James W. Alexander," with notes (2 vols. 12mo).

ALEXANDER, Joseph Addison, D. D., third son of Dr. Archibald Alexander, born in Philadelphia, April 24, 1809, died at Princeton, N. J., Jan. 28, 1860. He graduated at the college of New Jersey in 1826, and from 1826 to 1833 was adjunct professor of ancient languages and literature. He was afterward assistant teacher of Biblical and oriental literature in Princeton theological seminary, and in 1838 was elected by the general assembly of the Presbyterian church professor of Biblical criticism and ecclesiastical history. In 1852 he was transferred to the chair of Biblical and ecclesiastical history, which he occupied till his death. He published "The Psalms Translated and Explained" (3 vols. 12mo, 1850); "The Prophecies of Isaiah" (revised ed., 2 vols. 8vo, 1864), and an abridgment of the same work; a volume on primitive church government, and numerous essays in the "Biblical Repository" and "Princeton Review." At the time of his death he was engaged, in connection with Dr. Hodge, in preparing a commentary on the New Testament, of which "Notes on the New Testament Literature" and "The Gospel according to Matthew" have been published.

ALEXANDER, Ludwig Christian Georg Friedrich Emil, prince of Hesse, son of Louis II. of Hesse-Darmstadt, and brother of the present empress of Russia, born July 15, 1823. He served in the Russian army in the Caucasus, and distinguished himself in 1845 during the storming of Shamyl's residence. In 1851 he retired from the czar's service, and married the daughter of the late Russian general Count Hauke, who was raised to the rank of countess, and in 1858 to that of the princess of Battenberg. In 1852 he entered the Austrian service, took an active part in the war against Italy in 1859, and was charged by Francis Joseph to negotiate a truce with Napoleon III. In 1866 he commanded the 8th corps in the war against Prussia. He was repeatedly defeated, and was obliged to publish in 1867 his diary of the war in self-defence.

ALEXANDER, Stephen, LL. D., an American astronomer, born in Schenectady, N. Y., Sept. 1, 1806. He was educated at Union college and at Princeton theological seminary, was appointed tutor in the college of New Jersey in 1833, adjunct professor of mathematics in the same institution in 1834, professor of astronomy in 1840, of mathematics in 1845, and of mechanics and astronomy in 1854. In 1860 he went to the coast of Labrador at the head of an expedition to observe the solar eclipse of July 18. He has written many scientific papers, which have excited

considerable interest, including one on the "Physical Phenomena attendant upon Solar Eclipses," read before the American philosophical society at their centenary meeting in 1843; one on the "Fundamental Principles of Mathematics," read before the American association for the advancement of science in 1848; one on the "Origin of the Forms and the Present Condition of some of the Clusters of Stars, and several of the Nebulae," read at the meeting of the American association at Albany in 1850; and several communications to the same association relative to the "Form and Equatorial Diameter of the Asteroid Planets," and also on the "Harmonies in the arrangement of the Solar System, which seem to be confirmatory of the Nebular Hypothesis of Laplace."

ALEXANDER, William. I. First earl of Stirling, a Scottish poet, courtier, and speculator, born about 1580, died in 1640. He was the son of a private gentleman, was at an early age travelling tutor to the earl of Argyll, and about 1604 became attached to the court of James I., who in 1614 knighted him and appointed him gentleman usher to Prince Charles and master of requests. In 1621 he received a royal grant of Nova Scotia, and made strenuous efforts to sell it in parcels, issuing a glowing description of the country in a pamphlet entitled "An Encouragement to Settlers." To aid him, Charles I. in 1625 created the order of baronets of Nova Scotia, the title to be conferred upon purchasers of large tracts, and granted him the privilege of coining base copper money. According to Sir Thomas Urquhart, after selling 300 of these baronetcies, instead of 150, to which number they were to have been limited, and those who emigrated to the colony having failed to make a settlement, Alexander disposed of all rights and interests there to the French on his own account. He obtained from the king in 1628 a charter of the lordship of Canada, and from the council of New England a grant of territory, including Long Island under the name of the island of Stirling; and he had also received at different times royal grants of five baronies in Scotland. But notwithstanding all these favors, he died so involved that his family estates were given up to his creditors. He was appointed secretary of state in 1626, keeper of the signet in 1627, a commissioner of the exchequer in 1628, and an extraordinary lord of session in 1631. In 1630 he was created Viscount Stirling, and in 1633 earl of Stirling, Viscount Canada, &c. James I. called Alexander his philosophical poet. His works are numerous, and all didactic, heavy, and turgid, even when in the dramatic form. The principal are "Doomsday," in more than 10,000 lines, and "Four Monarchical Tragedies," viz.: "Darius," "Julius Cæsar," "Cæsus," and "The Alexandrian Tragedy." His titles expired with the fifth earl, his last male descendant, in 1739, but several claimants have since arisen. **II.** A major

general in the American revolutionary army, born in New York in 1726, died Jan. 15, 1783. Claiming the earldom of Stirling, to which many of his contemporaries believed him to be entitled, he is generally known in American history as Lord Stirling. Having received an excellent education, more particularly in mathematics, he attained a high reputation as a man of science. During the French and Indian war he was a member of the military family of Gen. Shirley, acting at different times as commissary, aide-de-camp, and secretary. After the close of the war he went to Scotland, where he spent a large portion of his fortune in the unsuccessful prosecution of his claims to the title and estates of Stirling. On the breaking out of the war of the revolution he was appointed colonel of a regiment, and while stationed at New York previous to the arrival of Washington from Boston, he fitted out an expedition consisting of a pilot boat and some smaller boats, with which he put to sea at night, eluding the vigilance of the sentinels of the British frigate *Asia*, which then lay in the harbor, and captured a transport laden with stores for the enemy at Boston. He opened the battle of Long Island, where, though he fought with obstinate bravery, he was compelled to surrender, after having secured the retreat of a large portion of his command. Having been exchanged, he fought under Washington at Brandywine, commanded the reserve at Germantown, and led a division at Monmouth. He died from an attack of gout. The name of Lord Stirling will always occupy an honorable place in American history, not only for his unquestioned patriotism and personal courage, but also for the part he took in exposing and defeating the designs of the "Conway cabal."

ALEXANDER OF APHRODISIAS (in Caria), surnamed the Expounder from his commentaries on Aristotle, flourished at the beginning of the 3d century of the Christian era. His most important work, "On Fate," in which he controverts the doctrine of necessity, was published by Orelli at Zürich in 1824. His other writings, mostly made up of notes upon Aristotle, were highly valued by the Arabs.

ALEXANDER ARCHIPELAGO. See ALASKA.

ALEXANDER BALAS, king of Syria from 150 to 146 B. C. He pretended to be a natural son of Antiochus Epiphanes, and his claim to succeed him was supported by the Romans and several of the princes of Asia. He defeated the troops of Demetrius Soter, and took possession of his throne, after which he abandoned himself to pleasure. Demetrius Nicator, son of Demetrius Soter, dethroned him and drove him into Arabia, where he was murdered by the chieftain with whom he had taken refuge.

ALEXANDER OF HALES, an English theologian, surnamed the Irrefragable Doctor, died Aug. 27, 1245. A great part of his life was passed at Paris, where he taught philosophy and theology.

In 1222 he became a Franciscan monk, and was the first of his order to retain his doctorate in the university. Bonaventura was his pupil, and perhaps also Aquinas. His chief work was his *Summa Theologia*, which, after being examined and approved by a committee of 70 doctors, was accepted as a complete manual of instruction in theology for all institutions of learning in Christendom.

ALEXANDER JANNÆUS, king of the Jews, of the house of the Asmoneans, from 105 to 78 B. C. (See HEBREWS.)

ALEXANDER JOHN I., prince of Roumania, of the house of Cuza, born in Galatz, March 20, 1820. He was educated in Paris, became a colonel in the Moldavian service, and held several civil offices, resigning in consequence of disagreement with the government about the Austrian occupation. He was an active partisan of the union party, which favored the political union of the two Danubian principalities, and was hostile to Austrian influence. He was appointed minister of war in 1858, and elected prince of Moldavia Jan. 17, 1859, and of Wallachia Feb. 5. In October, 1860, he obtained the recognition of the sultan, and on Dec. 23, 1861, he proclaimed the union of the two principalities under the name of Roumania. He dissolved the national assembly March 14, 1863, abrogated the electoral law May 14, 1864, and promulgated a new and entirely arbitrary constitution. A conspiracy formed against him in 1865 was suppressed, but one instigated in 1866 by Bratiano, Ghika, Cantacuzene, and other eminent public men, put an end to his reign. On the night of Feb. 23 they sent officers to his house, who forced him to sign his abdication. A provisional government was proclaimed April 13, 1866. Prince Charles of Hohenzollern, a relative of the king of Prussia, was chosen reigning prince, and Alexander Cuza has since lived in retirement at Vienna.

ALEXANDER KARAGEORGEVITCH, a Servian prince, born at Topola, Oct. 11, 1806. After the execution of his father, Czerny or Kara George, at Belgrade in 1817, his mother went with him to Wallachia. He was for some time in the Russian military service, until permission was granted for his return to Servia, when he became aide-de-camp of the reigning prince, Michael Obrenovitch. After the downfall of the Obrenovitch dynasty, Alexander was elected prince of Servia, Sept. 14, 1842. This choice was ratified by Turkey, but not by Russia. Both governments sent commissioners to Servia, and on June 15, 1843, he was reflected with the consent of the two powers. He promoted education and industry, and improved the civil and military service. He was soon accused, however, of leaning too much toward Turkey, especially during the Crimean war, when he prevented the national party from rising in rebellion against the Porte. The sultan rewarded his loyalty by confirming the privileges which he had granted to Servia, and by allowing the country to be placed, by the

terms of the treaty of Paris of March 30, 1856, under the collective protection of the great powers, instead of, as previously, under the sole protection of the Porte. A conspiracy against him was discovered in 1857, and its two ringleaders, the presidents of the senate and the supreme court of Servia, Stefanovitch and Rayovitch, were sentenced to death, and their six accomplices to hard labor for life. The popular feeling against this sentence ran so high that the authorities durst not execute it, while Alexander incurred still greater odium by invoking the assistance of the Turkish authorities for the detection and punishment of the conspirators. He was called upon to resign; and on his retiring to the fortress of Belgrade, under the protection of Turkish guns, his expulsion from the throne and the country was decreed by the Servian national assembly (December, 1858), and Prince Milosh Obrenovitch, then an octogenarian, was reinstated. Milosh, on his death, Sept. 26, 1860, was succeeded by his son, Prince Michael Obrenovitch. Alexander, living in Hungary, constantly intrigued with Servian revolutionists and foreign schemers. A conspiracy instigated by them in 1864 was frustrated, but that of 1868 resulted in the assassination of Prince Michael (June 10), but not in the overthrow of the Obrenovitch dynasty. Milan (Obrenovitch IV.), Michael's cousin and adopted son (born in 1854), was proclaimed his successor under a regency. The murderers were arrested, and 15 of them, including two brothers of Prince Alexander, were at once put to death, while the prince himself, convicted of having planned and given money for the execution of the murder, was sentenced to 20 years' imprisonment by the court of Belgrade. His surrender being demanded, the Hungarian authorities ordered a new trial at Pesth, and the evidence was not deemed sufficiently strong for his conviction. He was not molested in Pesth for nearly 18 months, when another trial took place (1870), which again resulted in his favor. In January, 1871, this verdict was reversed by a court of appeal, and he was sentenced to eight years' close imprisonment and to payment of costs; but the sentence has not been executed.

ALEXANDER NEVSKOI, a Russian hero and saint, son of the grand duke Yaroslav II. of Novgorod and Vladimir. Born in 1219, died in 1263. In his youth he fought against the Tartars, who, however, in 1228 succeeded in making Russia tributary. He was more successful in defending the northern boundaries against the encroachments of the Danes, the Swedes, and the knights sword-bearers. He won a great battle against the Swedes in 1240, on the banks of the Neva, near the modern St. Petersburg; hence his surname of Nevskoi. In 1243 he defeated the knights on the ice of Lake Peipus. On the death of his father in 1247 he became grand duke of Novgorod, and on that of his brother Andrew grand duke of Vladimir, and lord paramount

of all the other sovereign Russian dukes. To an embassy from Pope Innocent IV., sent to unite the western and eastern churches, he answered: "We know the true teaching of the church; we will neither accept yours nor hear anything about it." The Russian church canonized him, and his name is preserved in the national songs. Peter the Great erected to his memory a great monastery on the spot where the battle on the Neva was won, and created the order of Alexander Nevskoi.

ALEXANDER SEVERUS, Roman emperor from A. D. 222 to 235, the son of Gessius Marcianus and Julia Mamaea, born at Arce in Phœnicia, in the temple of Alexander the Great, during the attendance of his parents there at a religious festival. The date of his birth is uncertain, but most historians ascribe it to the autumn of 205. His original name was Alexianus Bassianus. On the elevation of his cousin Elagabalus to the purple, he accompanied his mother to Rome. In 221 he was adopted by the emperor, and created Cæsar, pontiff, consul elect, and *princeps juventutis*. He now assumed the name of Marcus Aurelius Alexander. Elagabalus soon regarded him as a rival whose destruction was essential to his own safety; but Alexander's life was preserved by the watchfulness of his mother and the affection of the soldiers, who ultimately avenged his injuries by sacrificing his enemy. On the death of Elagabalus he was proclaimed emperor by the pretorians, and the choice was confirmed by the senate. He now took the appellation of Severus, as he was ambitious of being thought a descendant of the emperor Septimius Severus. During nine years of peace he reformed abuses, promoted men of merit and capacity, and restored health to the empire. In 231, however, he assumed command of the eastern legions to defend his Asiatic provinces from a Persian invasion. Crossing the Euphrates, he encountered the hostile hosts in Mesopotamia, and defeated them with great slaughter. Receiving intelligence that the Germans were up in arms and preparing for an irruption into Gaul, he hastened back to place himself at the head of the Rhenish army; but at the very opening of the campaign he was waylaid and slain, along with his mother (to whose care his elevated character, in the midst of corruption, is attributed), by a party of mutineers, who had probably been instigated to the deed by his successor Maximin.

ALEXANDRE, Aaron, a chess player, born at Hohenfeld, Bavaria, about 1766, died in London, Nov. 16, 1850. He was for some time rabbi at Fürth, and afterward teacher of German at Paris, where he established a boarding school. His *Encyclopédie des échecs* (Paris, 1837), and his *Collection des plus beaux problèmes d'échecs* (Paris, 1846), established for him a high reputation as an authority on chess. He was among the first chess players of the century, and in his 80th year continued to be a thorough master of the game. In France

and in Europe generally he was known among chess players as "Father Alexander."

ALEXANDRETTA (Turk. *Iskanderun*; anc. *Alexandria ad Issum*), a Turkish seaport on the N. coast of Syria, in the vilayet of Aleppo, situated on the E. side of the bay of Iskanderun, in lat. 36° 35' N., lon. 36° E., 23 m. N. of Antioch; pop. about 1,000. Though much improved of late years, especially by the drainage of a pestilential marsh in its rear, it is still a wretched and unhealthy village. The harbor is capacious, and the town has considerable commercial importance as the port of Antioch and Aleppo. The products of northern Syria and Mesopotamia, consisting of grain, oils, soaps, gallnuts, wool, cotton, tobacco, &c., and European manufactures, pass through this port. English capitalists have projected a railroad from this port through the valley of the Euphrates to the Persian gulf, to be ultimately extended N. W. to Constantinople.—Alexandretta was founded by Alexander the Great to commemorate his victory over Darius III. in 333 on the neighboring plains of Issus. In 1097 it was taken by Tancred; and in 1832 it was the scene of a victory by the army of Mehemet Ali over the Turks.

ALEXANDRIA, a N. E. county of Virginia, on the Potomac, opposite Washington; area, 36 sq. m.; pop. in 1870, 16,755, of whom 7,310 were colored. It was once a part of the District of Columbia, and was retroceded to Virginia by act of congress in 1846. Its surface is hilly and its soil is poor and thin. The staple products are corn, wheat, oats, and hay.

ALEXANDRIA, a port of entry and capital of Alexandria county, Va., on the right bank of the Potomac, 7 m. below Washington; pop. in 1860, 12,652; in 1870, 13,570, of whom 5,300 were colored. The Potomac is here a mile wide, forming a harbor able to accommodate the largest ships. The city is generally well paved and lighted with gas, and water has been introduced by machinery. It is connected by a railroad 90 m. long with the Central railroad of Virginia at Gordonsville, and has a railroad to Leesburg, 40 m. distant, and one to Washington connecting with the Baltimore and Ohio railroad. It also has a canal joining the Chesapeake and Ohio canal at Georgetown. The imports from foreign countries in 1870 amounted to \$33,822, and the exports to \$39,648; 24 vessels were entered from foreign countries with a tonnage of 5,697 and crews of 192 men; 4 vessels with a tonnage of 1,029 were cleared for foreign countries. The number of vessels registered, enrolled, and licensed was 128, with a tonnage of 7,646. Two daily newspapers with tri-weekly editions and one monthly are published here.—The city of Alexandria belongs to the territory ceded by Virginia in 1789 to the Union as part of the District of Columbia, and retroceded in 1846. At the opening of the civil war Alexandria was in possession of the confederates. On the 24th of May it was entered

Alexandria, Egypt—Mehemet Ali Square.

by the Union forces under Col. Ellsworth, who was shot while hauling down a confederate flag. It was subsequently the seat of government of the few counties of eastern Virginia which adhered to the Union, being occupied by the federal army, and recognized Francis H. Pierpont as governor of the state.

ALEXANDRIA, a town, capital of the parish of Rapides, La., on the Red river, about 50 m. (direct) from its junction with the Mississippi; pop. in 1870, 1,218, of whom 448 were colored; in 1860, 1,461. It is the shipping point of a rich cotton country.—When the Shreveport expedition of Gen. Banks and Admiral Porter was descending the river in April, 1864, the fleet, owing to low water, was unable to pass the falls at Alexandria, and the destruction or capture of all the vessels, valued at nearly \$2,000,000, seemed inevitable. In this emergency Lieut. Col. Joseph Bailey, engineer of the 19th corps, proposed to construct a dam across the channel of the river—here 758 feet wide, 4 to 6 feet deep, and running at the rate of 10 miles an hour—a short distance below the falls. Eight days' work had nearly completed the dam, and the water had risen enough for all except the largest vessels to pass, when a portion of the work gave way. Admiral Porter immediately ordered the four smaller vessels of the fleet to pass through the breach, which, though attended with great danger, was successfully accomplished. Several wing dams directly at the head of the falls were now constructed, raising the water on the rapids more than a foot additional, when the rest of the fleet passed safely down. The town was nearly destroyed by an accidental fire on the day of its evacuation by the federal troops, May 13 following.

ALEXANDRIA (Turk. *Iskanderiyeh*), a city of Egypt, on the Mediterranean, 112 m. N. W. of Cairo, founded by Alexander the Great after the destruction of Tyre, 332 B. C. Dinocrates or Dinocrates was the architect, and the site selected was at the Canopic mouth of the Nile, between the sea and Lake Mareotis. The city was regularly laid out and intersected by two main streets, upward of 100 feet wide, running from N. to S. and from E. to W. respectively. On the island of Pharos a lighthouse of vast height was erected, and this island itself was connected with the mainland by a dike which divided the inner from the outer harbor, and through which vessels could pass by means of movable bridges. The east end of the town was called the Bruchium, and here was the royal palace of the Ptolemies. Under them Alexandria was the great centre to which the trade of Europe and the Mediterranean with Persia and the far east converged. It numbered about 300,000 free inhabitants, of various nationalities, and also became the centre of universal learning. Here the schools of Grecian philosophy, and especially the Platonists, flourished. Among its ornaments were its library and the museum, an establishment in which scholars were maintained at public cost. In Alexandria the Scriptures were first made known to the heathen by the Septuagint version, and here Christianity early took root, although the city soon became the scene of rancorous and unchristian disputation and violence. In no place were religious conflicts more frequent or more sanguinary. It also witnessed much political strife, suffering especially during the struggle of Cleopatra with her brother Ptolemy (Cæsar's Alexandrine war). In 30 B. C. it fell permanently under the power

of the Romans; and, notwithstanding the removal of many of the most precious works of art to Rome, its greatness continued till the establishment of the seat of empire at Constantinople. From the rise of Constantinople, though still a centre of commerce, Alexandria as a capital began seriously to decline. In A. D. 640 it was taken by the Saracens under Anru, the general of the caliph Omar, and in 969 Cairo was founded by the caliphs of the Fatimite dynasty, and made the capital of Egypt. The discovery of the route to India and the East by the Cape of Good Hope completed its decay. At present the underground cisterns for the preservation of the Nile water are the only perfect relics of the past.—Modern Alexandria is situated on the causeway which once formed the communication between the mainland and the Pharos, and which by constant accumulation of sand and material is now formed into a neck of land. There are two ports, one at the extremity of an extensive roadstead west of the Pharos, in which vessels of the line may lie; the other, the modern port, on the east of the Pharos, is less advantageous. Lake Mareotis was dried up by accumulations of sand, but in 1801 the British army cut through the narrow strip which separated it from the lake of Aboukir, and let in the sea again. Alexandria is fast becoming as populous as it was in the days of antiquity, and looks (1873) rather like an Italian than an oriental city. The ruins of the ancient city and the wretched habitations of the Arabs are no longer as conspicuous as they were formerly. Large streets well paved and lighted with gas are seen in the European quarter, and abound with fine residences. The great promenade of the Mehemet Ali square, formerly the square of the Consuls, is the central and most animated point of the city. The population was estimated in 1870 at 238,888, including, besides Arabs, Copts, Turks, Persians, Armenians, and Jews, 25,000 Greeks, 20,000 Italians, 15,000 French, 12,000 English Maltese, 12,000 Levantines of miscellaneous European descent, 8,000 Germans and Swiss, 8,000 various foreigners, comprising a number of American officers in the Khedive's army and American engineers and missionaries. Railways connect the city with Cairo and the Suez canal and with Ramleh. It is as a place of transit for passengers that Alexandria is most remarkable, the steamers to and from India, the Mediterranean, and the Levant all contributing to the prosperity of the city. In 1869 there were 56,000 passengers in the 2,000 sailing ships, and nearly 80,000 in the 1,000 steamers which entered the port, besides men-of-war.

ALEXANDRIAN CODEX, an uncial manuscript of the Old and New Testament, so named from the fact that it was found at Alexandria by Cyrillus Lucaris, the patriarch of Constantinople, who presented it in 1628 to Charles I. of England. It was written on vellum, in double columns, condensed and unaccented.

It contains, besides the canonical books, slightly varied in their order, most of the apocrypha. Some writers have been of the opinion that the writer of this codex followed three different editions—the Byzantine in the gospels, the western in the Acts and catholic epistles, and the Alexandrine in the epistles of Paul—and therefore speak disparagingly of its authority. Others consider it the most perfect copy of the Scriptures extant. The famous passage concerning the three witnesses (1 John v. 7) is not contained in this codex; and there are several chasms in the text, more especially in the New Testament. A portion of the gospels of St. Matthew and of St. John, as well as of the Second Epistle to the Corinthians, is wanting. On the first page of the text of Genesis is a declaration that the MS. was dedicated to the use of the patriarch of Alexandria, and an anathema of excommunication against him who shall remove it from the library. Cyrillus, the donor of the MS. to Charles, was a patriarch of Alexandria before his removal to Constantinople. By some he has been accused of forgery in this whole matter. The MS. is in very good condition generally. It is the only one known which contains the genuine epistle of Clement to the Corinthians. This codex is now preserved in the British museum.

ALEXANDRIAN LIBRARY, a collection of books formed by Ptolemy I. and Ptolemy II. of Egypt, and probably the largest prior to the invention of printing. It was founded, it is said, at the suggestion of Demetrius Phalereus, who, when a fugitive at the Egyptian court, spoke with admiration of the public libraries at Athens. Demetrius was appointed superintendent, and diligently employed himself in the collection of the literature of all nations, Jewish, Chaldee, Persian, Ethiopian, Egyptian, Greek, Roman, &c. According to Eusebius, there were 100,000 volumes in the library at the death of Ptolemy Philadelphus; and subsequently the number was increased to 700,000. The *volumina* or rolls, however, contained far less than a printed volume; as, for instance, the "Metamorphoses" of Ovid, in 15 books, would be considered as 15 volumes. During the siege which Cæsar stood in Alexandria, a large part of the library was burned. Gibbon asserts that the old library was totally consumed, and that the collection from Pergamus, which was presented by Mark Antony to Cleopatra, was the foundation of the new one, which continued to increase in size and reputation for four centuries, until dispersed by Theophilus, patriarch of Alexandria, at the destruction of the Serapeum, about A. D. 390. Still the library was reestablished; and Alexandria continued to flourish as one of the chief seats of literature until it was conquered by the Arabs in 640. The library was then burned, according to a story of very questionable authenticity, in consequence of the fanatic decision of the caliph Omar: "If these writings of the Greeks agree with the Book of God,

they are useless and need not be preserved; if they disagree, they are pernicious and ought to be destroyed." Accordingly, it is said, they were employed to heat the 4,000 baths of the city; and such was their number, that six months were barely sufficient for the consumption of the precious fuel. There is no doubt, however, that after 640 the library ceased to exist as a public institution. Connected with the library was a college, or retreat for learned men, called the museum, where they were maintained at public expense.

ALEXANDRIAN SCHOOL, a term vaguely applied to a development of Neo-Platonism by the philosophers of Alexandria in Egypt about the end of the 2d century. The characteristic of the school was a broad eclecticism based upon the rationalism of Plato and largely influenced by the supernaturalism of the Grecianized Jews. Afterward the early teachers of Christianity modified it still more by an admixture of Aristotelianism, and it became a transition system between the pagan and Christian beliefs, aiming to harmonize all philosophy and all religion. The earliest philosopher of this school was the Jew Philo, but it first took decided form from Ammonius Saccas, about 193. The other chief names identified with it are those of Plotinus, Porphyry, Iamblichus, Hierocles, Proclus, Pantanus, Clement, Origen, Athanasius, Gregory Nazianzen, and Cyril. Of these, Philo represents the Judaistic extreme, while Clement is the great Christian Alexandrian.—The history of the Alexandrian school has been written by Matter (2 vols., Paris, 1840-44) and Simon (2 vols., Paris, 1844-5). See also *De l'école d'Alexandrie*, by Barthélemy Saint-Hilaire (Paris, 1845).

ALEXANDRINE, or **Alexandrian**, in poetry, a metre consisting of 12 syllables, or 12 and 13 alternately; so called, according to some, from a poem on the life of Alexander written in this kind of verse by a French poet of the latter half of the 12th century. The French have ever since cultivated this species of verse more than any other European nation. Their tragedies are mostly composed of Alexandrines. In his "Essay on Criticism," Pope gives the English opinion of them:

A needless Alexandrine ends the song,
That like a wounded snake drags its slow length along.

ALEXANDROPOL (formerly *Gumri*), an important fortress and town in Russian Armenia, near the frontier of Turkey, 54 m. N. W. of Erivan; pop. in 1870, 17,272. Near it the Russians under Bariatinski obtained on Oct. 30, 1853, a great victory over the Turks.

ALEXANDROV, a town of Russia, in the government of Vladimir, 58 m. N. E. of Moscow, on the river Seraya; pop. in 1870, 5,810. It contains dye works and manufactories of iron ware and muskets. Among the many churches is one with a nunnery and the tombs of Martha and Theodosia, two sisters of Peter the Great. The czar Ivan II. Vasilievitch established here the first

printing press introduced into Russia, and in 1560 made the town the capital of his newly founded dominion of Opritchina. Near the town is an extensive imperial stud of horses founded by the empress Elizabeth in 1761 and completed in 1781, famous for the variety of the breeds.

ALEXANDROVSK, a town of Little Russia, on the left bank of the Dnieper, below its cataracts, in the government and 48 m. S. of Ye-katerinoslav; pop. in 1870, 4,601. It is the place of shipment by the Dnieper for the Black sea, though the trade might be much more active considering the excellent situation of the town. The district of Alexandrovsk formerly contained the lines of fortifications from the Dnieper to the sea of Azov, established in 1770 against the Tartars. The neighboring village of Stilja is noted for its extensive coal mines. Many settlements of foreigners, chiefly Germans, are in this district.

ALEXEI, the Russian form of Alexis. See **ALEXIS**.

ALEXIS (or **Alexius**) **I.**, **Comnenus**, emperor of Trebizond (Trapezus), born in 1182, died in February, 1222. The enmity of Isaac Angelus to the family of the Comneni threatened the entire extermination of that illustrious house. The sons of the last Comnenian emperor of Constantinople, John and Manuel, were by his command mutilated and murdered in prison. The latter, however, left two infant sons, Alexis and David, who fled with their mother to their relative Thamar, the Georgian queen of Tiflis, by whom they were protected and educated. They gradually formed a dominion on the banks of the Phasis, which the distracted government of the Angeli failed to suppress. On the second capture of Constantinople by the Latins, in 1204, Alexis and his brother rallied around them numerous discontented Greeks, left their retreat, and passed the Phasis. Alexis captured Trebizond, Cerasus, and Mesochaldion, and took possession of all that coast of the Black sea as far as Amisus, while David advanced beyond the Halys, took Sinope, and pushed his conquests to the environs of Constantinople. Alexis now assumed the imperial title, proclaiming himself king and ruler of all Anatolia. His reign was troubled by perpetual wars with the Turks, and with Theodore Lascaris, who having, like Alexis, become master of a fragment of the empire, was entitled the emperor of Nicæa. In 1214 Alexis concluded a peace with Theodore, but the same year fell into the hands of the sultan of Iconium, and purchased his liberty by yielding to the Turks the town and district of Sinope. His empire at his death was reduced to the coast of the Black sea, comprised between the Phasis on the east and the Thermodon on the west.

ALEXIS (or **Alexius**) **I.**, **Comnenus**, emperor of Constantinople, born in 1048, died Aug. 15, 1118. He was the son of John Comnenus, who refused the succession bequeathed to him

by his brother Isaac. Alexis in his youth served the emperor Michael VII. in the Turkish war, and against the rebel Nicephorus Botaniates. He was one of the most faithful adherents of Michael till he was deposed by his rebel enemy, when he offered his services to the new emperor. Nicephorus bestowed honors upon him, and charged him with restoring the peace of the empire, then disturbed by many rebellions. Alexis triumphed over the most powerful leaders of revolt, Bryennius and Basilacius, but his victories excited the jealousy of the emperor and the envy of the courtiers; and when he refused to march against a new rebel, the husband of his sister, his destruction was resolved upon. Escaping by the protection of the empress to the army, of which he was the favorite, he was immediately proclaimed emperor by the soldiers, captured Constantinople in 1081, and gave it up to pillage. Nicephorus was permitted to retire to a convent. Alexis found the empire in internal discomposure, and surrounded by enemies. On the east the Seljuk Turks, overrunning the provinces of Asia, had spread from Persia to the Hellespont; on the west, the Normans, under Robert Guiscard, after brilliant successes in Italy, were advancing eastward; and new swarms of barbarians from the north, having crossed the Danube and occupied Thrace, had several times defeated the imperial troops. The first measure of Alexis was to conclude a peace with the Turks by abandoning to them the provinces of which they already had possession. Heavy exactions and spoliations of the churches furnished him the means to at once raise an army of 70,000 men, with which he marched for the deliverance of Durazzo, besieged by the Normans. His treaty with the sultan had procured him an auxiliary force of some thousand Turks, and he had even succeeded in enlisting under his banner some of the wild Transdanubians. The battle was fought Oct. 18, 1081; and the Normans, led by Robert and his wife Gaita, gained a complete victory. Robert was now obliged by a revolt of his vassals to return for a time to Italy, which gave Alexis leisure to repel the incursions of the Turks. By means of his navy he contended with doubtful success against them till 1095, but was in despair when he learned that the Turks had availed themselves of the art of some Greek prisoners to build a fleet, with which they were approaching Constantinople. He now addressed himself for aid to the West, declaring that the existence of Christendom was threatened by this new eruption of barbarians. The capture of Jerusalem by the Moslems, the preaching of Peter the Hermit, and the activity of Pope Urban II., produced a meeting of the Christian princes at Piacenza. The ambassadors of Alexis contributed much toward deciding the princes to join the first crusade. Alexis had thought only of a moderate succor from the West; when therefore in 1096 the promiscuous armies

of the crusaders began to arrive, numbering untold hosts, and led on by the most renowned leaders of Europe, his fears were quite as great as his hopes, and he was glad to give them a quick passage into Asia, where at first the Turks found little difficulty in annihilating them. Godfrey of Bouillon and Hugh, count of Vermandois, encamped during the winter in the environs of Constantinople, and it was only by a skilful display of his military forces that the emperor felt his capital safe. He failed to give them the assistance which he had promised, and in 1097 demanded from the chiefs of the crusade that they should restore to him his ancient possessions in Asia, and should do homage to him for all the territory which they conquered out of certain prescribed limits. They consented, though Bohemond, the son of the emperor's old enemy Robert Guiscard, long refused, and Tancred passed over into Asia to avoid the public ceremony of doing homage, at which Count Robert of Paris insulted before the world the imperial majesty. Harmony never existed between Alexis and the leaders of the crusades; and though he rendered them important assistance in the siege of Nicæa, and by their aid recovered some important towns of Asia Minor, and the islands of Rhodes and Chios, yet by abandoning the Christians before Antioch, he so outraged Bohemond that that prince returned to Europe, increased his army, and began to wage war in Thrace against Alexis. He, however, gained but slight successes, and soon made peace. In the last years of his life Alexis continued to war against the Turks, and defeated them in great battles in 1115 and 1116. Alexis was an able ruler, valiant, active, and politic; but he was also dissembling and hypocritical.

ALEXIS, Willibald. See HÄRING.

ALEXIS MIKHAILOVITCH, second czar of Russia of the Romanoff lineage, born March 10, 1629, succeeded his father Michael Fedorovitch July 12, 1645, died Jan. 29, 1676. During the earlier years of his reign he had for advisers his tutor, Morozoff, and the grand chancellor Plesoff. An insurrection broke out against his counsellors, and Plesoff was slain. Next (1648) appeared two pretenders to the crown: one calling himself Dimitri (the last pretender who took that name), the other a certain Ankudinoff, calling himself a son of the czar Basil Shuiskoi. Alexis put them down, and afterward proved himself one of the best sovereigns who ever occupied the Russian throne. His reign marked the dawn of that civilization which his son Peter the Great more widely diffused over Russia. He encouraged learning, fostered printing establishments, attracted to Russia from abroad men of letters, artists, physicians, manufacturers, and operatives. He was active, intelligent, and temperate. To break the pride of the princes and boyars, who refused generally to obey the orders of a military or civil superior when the date of his title was later than their own,

Alexis ordered these rebels to deposit all the documents relating to their rank in the chancery of the imperial council, and then burned them together with the old nobiliar record of the empire, called the Velvet Book. Under his reign Russia for the first time began to have the advantage over the Poles, whom he defeated in two wars. By the treaties of Moscow (1656) and Andruszow (1667) Alexis recovered several provinces formerly taken from Russia. He was also for several years at war with Sweden, which ended with an armistice in 1658 and a treaty in 1661, mutually guaranteeing their former possessions. During his reign the Cossacks of the Ukraine, for centuries tributaries of Poland, seceded and submitted to Russia. He was twice married, and left children by both wives. The first was a Miloslavska, of a Russian boyar family; the second a Naryshkin, a person of lower rank, whom Alexis chose from the sight of her shoe, which made him think she had a very small foot. She was the mother of Peter the Great.

ALEXIS PETROVITCH, the eldest son of Peter the Great and of Eudoxia Lapukhin, born in Moscow, Feb. 18, 1690, died July 7, 1718. Surrounded from childhood by the relations of his mother, he was the centre of all those who were, like her, averse to the reforms introduced by his father. He affected a fanatic love of old Russian customs and superstitions, and Peter decided to exclude him from the throne. Alexis, then about 22 years old, seemingly consented to this plan, saying it was his wish to become a monk. He entered a monastery, but still kept up his intercourse with the malcontents, with his mother, who had likewise been shut up in a convent, and with her numerous dissatisfied relations. During the travels of Peter through various European countries in 1717, Alexis announced that he had received the order of his father to join him abroad. He thus managed to escape to Vienna, where he claimed the protection of the German emperor, and thence he went to Naples. Peter sent after the fugitive Rumiantzoff, captain of the guards, and Tolstoi, the privy councillor, who, partly by coaxing, partly by menaces, succeeded in bringing him back to St. Petersburg. On Feb. 2, 1718, Peter disinherited Alexis, impeaching him and many of his kindred and advisers for high treason. He was found guilty by the great council of the empire and condemned to death. Peter pardoned him, but he died July 7, 1718, a few days after the condemnation, some say from fear and excitement; but the more general belief is, that he was either poisoned or secretly beheaded by the order of his father. Peter himself published the proceedings of the trial. Alexis, when very young, was married to a princess of Wolfenbüttel, who died in 1715, leaving a daughter, and a son who reigned afterward as Peter II.

ALFANI, the name of two Italian painters, Domenico di Paris, born in Perugia about 1483,

died after 1540; and Orazio di Paris, son of the former, born in Perugia in 1510, died in 1583. Their pictures have often been confounded with each other, and also mistaken for those of Raphael.

ALFARABIUS, an Arabian philosopher, died about 950. He travelled, acquired the knowledge of a large number of languages, and settled at Damascus, where he was joyfully received by the Abbasside caliph, who settled a pension upon him. He led an extremely temperate life, approaching asceticism. His writings were very voluminous and comprehensive, and he is reputed to have been the first who attempted the compilation of an encyclopædia, the MS. of which is in the Escurial.

ALFIERI, Vittorio, count, an Italian tragic poet, born at Asti, Piedmont, Jan. 17, 1749, died in Florence, Oct. 8, 1803. He received a very imperfect education at the college of nobles in Turin, which was terminated by his entrance at the age of 17 into the army. As his regiment was a provincial one, from which only a few days' service at stated annual periods was required, he easily obtained the royal assent to an extended leave of absence for the purpose of travel. With ample wealth, a restless and excitable temperament, and a keen appreciation of the pleasures of life, he passed several years in wandering over the continent, and in 1773 returned to Turin. This period of travel was without any considerable benefit to him, being spent in a great measure in frivolous dissipation, and at the age of 25 he had given no hint of any dramatic talent or literary ability. Chance seems to have led him, while watching at the sick bed of his mistress, to sketch a few scenes in Italian between Antony and Cleopatra. Crude as these necessarily were, the occupation developed his latent powers and gave the first impulse to literary composition. It awakened in him also the desire to lead a more profitable and reputable life. "Cleopatra" was gradually finished, and, together with a farce called "The Poets," was in 1775 produced with considerable success on the stage. His labors on these pieces having revealed to him his ignorance of the structure and resources of his own language, at the age of 27 he deliberately set about educating himself in Italian. A year or two of study in the society of learned men sufficed to familiarize him with the works of the classic writers of Italy, ancient and modern, and in 1777 he returned with enthusiasm to his dramatic labors. At this time he met the beautiful and accomplished countess of Albany, the ill-treated wife of Charles Edward Stuart, pretender to the English crown. For this lady he conceived an absorbing passion, and the desire to win her approbation stimulated his genius to higher efforts. To be near her he took up his residence in Florence, having first settled the bulk of his fortune upon his sister, while reserving to himself an annuity; and during the next few years he labored with an energy and success

which fairly redeemed the lost opportunities of his youth. By the year 1782 he had produced 14 dramas. In 1785 he followed the countess to France, and upon the death of her husband in 1788 is believed to have been married to her in that country, although the relation was never publicly acknowledged, and there is no positive evidence to sustain it. He continued to reside in France, and was engaged in superintending the publication of an edition of his works in Paris when the French revolution reached its first alarming crisis. Compelled to flee the country, with the loss of almost everything he had possessed there, he returned to Florence, where, in the society of the countess of Albany, he passed the remainder of his life. His latter years were clouded by various troubles, but he still pursued his literary labors. He wrote satires, panegyrics, and sonnets, translated Virgil and Terence, and when nearly 50 years of age began the study of Greek. He died of an attack of gout, tenderly cared for to the last by the countess of Albany, who caused a monument, sculptured by Canova, to be erected over his remains in the church of Santa Croce. His dramatic works comprise 21 tragedies, 6 comedies, and a "tramelogedia," a name invented by himself. He also produced translations from the Greek dramatists, an epic poem in four books, a treatise on tyranny, and a number of satires and lyrical pieces, including five odes on the American revolution. After his death appeared his *Misogallo*, a collection of satirical pieces in prose and verse, inspired by a lively hatred of the French nation; and his autobiography, in which he records with singular frankness the story of his life.—Alfieri's reputation rests almost exclusively upon his tragedies. Their literary rank is permanent. Remarkable for a vigor and intensity of expression worthy of the best days of Italian literature, their classic subjects and stern outline, however opposed to the romantic school, have a grand and solemn charm. Though simple to meagreness in construction, and admitting of little by-play or scenic effect, they are said to hold an Italian audience spell-bound by the nervousness of the language and the condensed energy and passion with which the higher passages are infused. *Saul*, *Mirra*, *Oreste*, and *Filippo* are considered the best. To Alfieri belongs the distinction of having founded the Italian school of tragedy. Avoiding pedantic obedience to Greek or French models, he embodied the earnestness of the one and the modern form of the other in the language of his country. He was a man of strong likes and dislikes and a violent temper, but candid, independent, and generous to a fault. Two marked peculiarities of his character were his detestation of the French and his fondness for horses. He was a liberal in politics, although his faith in democracy is supposed to have been somewhat shaken by the excesses of the French revolutionists; he hated kingeraft, and prized his own nobility chiefly that he was free to abuse it.

Two editions of Alfieri's complete works have been published—22 vols. 4to, Pisa, 1808, and 22 vols. 8vo, Padua, 1809-'10. The best edition of his tragedies, autobiography, and some of his minor works, is contained in the Milan collection of the Italian classics, entitled *Opere scelte* (4 vols. 8vo, 1818).

ALFONSO, the name of several kings of Spain and Portugal, also written ALONZO, ALONZO, and ALPHONSO, and in Portuguese AFFONSO. There were five in Aragon, six in Portugal, and twelve in Leon and Castile. The kingdom of Leon is generally considered to have commenced with **Alfonso I.**, the Catholic, who was elected about 739 king of Asturia, subsequently called the kingdom of Leon and Oviedo, and died in 757. He carried on a war of extermination with the Moors.—**Alfonso II.**, the Chaste, grandson of the preceding, elected king in 791, died in 842. He is famous in the national annals for having abolished the annual tribute of 100 Christian maidens to the Moors. In his reign lived the great Bernardo del Carpio, the hero of Spanish romance.—**Alfonso III.**, the Great, son of Ordoño I., born in 848, king in 866, died in 912. He extended the limits of the Christian rule to the Guadiana, put down a rebellion fomented by discontented nobles in favor of his son Garcia, but afterward abdicated, and won a victory over the infidels as general of his son's troops.—**Alfonso VI.**, the Valiant, son of Ferdinand I., born in 1030, succeeded to the throne of Leon in 1065, and died in 1109. Under the preceding reign the kingdoms of Leon and Old Castile had been united, and after much internal warfare with his brothers, among whom the father had parcelled out the kingdom, Alfonso made himself master of Leon, Old Castile, the Asturias, and Galicia. His successes against the Moors led to the invasion of the peninsula by the Almoravides from Africa, against whom Alfonso furnished assistance to his old enemy the king of Seville, but ineffectually. Rodrigo Diaz de Bivar, the celebrated Cid, lived in this reign. Alfonso VI. died without heirs male, and the united crowns fell to his daughter Urraca. She married Alfonso I. of Aragon, who in her right claimed the crown of Castile and Leon. The marriage was, however, dissolved on account of Queen Urraca's misconduct.—**Alfonso VII.** or **VIII.** (see ALFONSO I. of Aragon), RAIMONDEZ, son of Queen Urraca and her first husband, Count Raymond of Burgundy, born in 1105, died in 1157. He was proclaimed king of Galicia in 1109, was for some time at war with his mother, and succeeded her in Leon and Castile in 1126. In 1135 he was crowned emperor of Spain, though he hardly possessed a third of it, and did not transmit the title.—**Alfonso X.**, the Wise, king of Leon and Castile, born in 1226, succeeded his father Ferdinand III. in 1252, and died in 1284. He compelled the king of Granada to do homage to the crown of Castile, and to pay a considerable sum of money. In 1256 Alfonso

was chosen by some of the electors emperor of Germany, while Richard of Cornwall was supported by others; but his power in Germany remained a mere shadow, and in 1273 Rudolph of Hapsburg put an end to the interregnum. His reign was disturbed by the revolt of his brother Philip and Alhamar, king of Granada, an invasion by the king of Morocco, and a civil war caused by the claim of his second son Sancho to be recognized as heir to the throne. Sancho was excommunicated by the pope and the kingdom placed under an interdict. Alfonso was one of the most learned men of his age. He laid the foundation of Spanish prose by causing a translation of the Bible to be made into that language, by ordering all legal proceedings to be conducted in it, and by the excellent specimens which he himself gave of it in his writings. He is also distinguished as a poet and as a man of science. He is best remembered, however, for his celebrated body of laws, known usually as *Las siete Partidas* ("The seven Parts"), but named by its author the *Setenario*, from a code begun by his father. The materials for this work were drawn from the code of Justinian, the Visigothic laws, the local institutions of different parts of the kingdom, and other sources. Its enforcement was long resisted by the great cities, but it was at last in 1348 established on a firm footing, and has been ever since the basis of Spanish common law, and has even, by the admission of Florida and Louisiana into the United States, been introduced into the legal system of our own country. Another important work of which Alfonso is the author is the *Crónica general de España* ("General Chronicle of Spain"). He established on a firm basis the university of Seville, and was eminent for his astronomical and mathematical attainments, and for his researches in alchemy. The astronomical tables which bear his name, and were probably constructed by Moorish astronomers invited to his court for that purpose, were celebrated for a long time. His astronomical works have been published in several volumes, by order of the Spanish government, edited by Manuel Rico y Sinobas (1864 *et seq.*).

ALFONSO I., king of Aragon and Navarre, surnamed el Batallador (the battler), son of Sancho V., succeeded his brother Pedro I. in 1104, died in 1134. He married Urraca, daughter of Alfonso VI. of Leon and Castile, and in her right claimed the sovereignty of those states also, and is sometimes counted as Alfonso VII. of that line. The first years of his reign were distracted by violent quarrels and wars with his wife, whom he finally divorced in 1114. The Moors under Ali ben Yusuf invaded the province of Toledo, and carried terror to the gates of the capital of Christian Spain; a second army appeared in Portugal; and a third laid siege to Barcelona. Alfonso fought an indecisive battle with these last in 1111, after which they abandoned Catalonia. Subsequently he directed his arms against the

invaders in other quarters, and rescued almost all the territory S. of the Ebro from Mohammedan domination. He took Saragossa (1118) after a four years' series of operations, and made it his capital. In 1125 he invaded Andalusia at the invitation of the Mozarabes, or Christian inhabitants of that country; and though he failed in the siege of Granada, he performed the remarkable feat of leading an army through hostile territory from Saragossa to the Mediterranean, somewhere between Málaga and Almeria, and back again, without serious loss. On the death of his divorced queen he made preparations to enforce his claims in Castile, but was persuaded by the church to agree to a truce and renounce the title of emperor of Spain, which he had assumed. He finally undertook to secure the free navigation of the Ebro by reducing the Moorish city of Tortosa near its mouth. As a preliminary to this enterprise he besieged Fraga, on the Ciuga, an affluent of the Ebro, and was there slain in battle—the only engagement, it is said, in which he was ever vanquished.

ALFONSO V. of Aragon, and I. of Naples and Sicily, surnamed the Magnanimous, born about 1390, died June 27, 1458. He succeeded his father Ferdinand I. in 1416, and the first act of his reign displayed the generosity of his character. Having received a list of nobles who were conspiring to dethrone him, he tore the paper in pieces without reading it. In the early part of his reign he left Spain to make good his claims to the sovereignty of the islands of Sardinia and Corsica, which were then partly in the power of the Genoese. In the war which followed he met with some success, but soon relinquished this project for more dazzling schemes of ambition. Joanna, queen of Naples, being attacked by Louis III., duke of Anjou, sent to Alfonso, offering to make him duke of Calabria and heir to the throne of Naples if he would aid her against the duke of Anjou. Alfonso eagerly accepted this proposition, abandoned Sardinia and Corsica, over which his sovereignty thenceforth amounted to but little, and, sailing to Naples, obliged the duke of Anjou to raise the siege, and make a peace on terms advantageous to the queen. But Joanna became jealous of the power of her new ally, and open war broke out between them. The queen summoned to her aid Sforza Attendolo, the general of the duke of Anjou, who defeated Alfonso. The latter was soon enabled by the arrival of fresh troops from Spain to make himself master of the city of Naples, and to hold his enemies in check. But his presence was now required in Spain to protect his kingdom of Aragon, then at war with Castile. Accordingly, leaving his brother Don Pedro in charge of his affairs in Italy, he sailed for Spain in 1423. On his way thither he made a descent on Marseilles, then belonging to the duke of Anjou, captured the city without difficulty, but neither sacked it nor carried away from it any booty, with the

exception of the body of a dead saint, Louis, formerly bishop of Toulonse. Alfonso passed about eight years in Spain, and then again turned his attention to Italy. Here the Spaniards, pressed by the queen, the pope, the dukes of Anjou and Milan, and the Genoese, had been almost overwhelmed. Alfonso arrived in 1432, and, seeing the desperate state of affairs, sailed to the island of Jerba on the coast of Africa, which he conquered, after gaining a victory over the bey of Tunis, to whom the island belonged. After this exploit he returned to Italy, where he engaged in negotiations to bring about a reconciliation with Queen Joanna, and in intrigues to obtain adherents. In 1435 the queen died, bequeathing her crown to René of Anjou, count of Provence, brother and successor of Louis III., who had died some time before; and Alfonso, thinking the occasion a favorable one for asserting his claims, renewed the war, and besieged the city of Gaeta by sea and land. But in a naval battle near the island of Ponza, he was totally defeated by the Genoese and the duke of Milan, and was taken prisoner with a great number of his followers; and shortly afterward his land forces were routed and dispersed under the walls of Gaeta. Having by his nobleness of disposition and gallant bearing gained the affection of his captor, the duke of Milan, the latter set him at liberty and became his ally, and Alfonso was thus enabled to resume his operations under better auspices. After a contest of several years without effecting much, he succeeded, by the treachery of one of the adherents of René, in making himself master of Naples in 1442, and compelled René to seek refuge in Provence. Alfonso was soon after recognized as king of Naples by the assembled states of the kingdom, and by Pope Eugenius IV., who also issued a bull legitimatizing Ferdinand, the bastard son of the king. From this time Alfonso resided in Naples, exerting himself to improve the condition of that kingdom, the affairs of which, during the reign of Joanna II. and the disturbances which followed, had fallen into much disorder; and, though taking part in some Italian wars of little importance, he passed the remainder of his life in comparative quiet. At his death his brother John inherited the crowns of Aragon, Sardinia, and Sicily, while his son Ferdinand received that of Naples.

ALFONSO I., the first king of Portugal, son of Henry of Burgundy, count of Portugal, died in 1185. He was several times at war with the kingdom of Castile; but on the establishment of peace he turned his arms against the common enemy, the Moors, and fought a battle in 1139, on the plains of Ourique, against the Moorish king of Badajoz and his allies, which completely broke the Moslem power in Portugal. After this victory he assumed the royal title. In 1146 he took the town of Santarem after an obstinate defence, and put to the sword every living soul; and the following

year Portugal was free. He instituted a code of laws, still known as the laws of Alfonso. He was succeeded by his son Sancho I.

ALFONSO V., king of Portugal, surnamed the African, born in 1432, succeeded his father Duarte in 1438, died at Cintra, Aug. 28, 1481. During his minority the regency was held first by his mother and afterward by his uncle Dom Pedro, whose daughter the young king married on coming of age. A few years later Dom Pedro was declared a rebel and killed in battle, but Alfonso soon became convinced of his loyalty, paid great honors to his memory, and punished those who had traduced him. During his reign the Portuguese discovered and colonized Guinea. In answer to the call of Pope Calixtus III. for a general crusade against the Moslems, he equipped a fleet of 250 vessels for an expedition to Africa, and in 1458 landed near Tangier with 20,000 men. It was not until 13 years later that he found himself, after severe campaigns, master of Tangier and several other cities, his conquests surpassing in importance those of any other Portuguese monarch in Africa. Having been affianced to Joanna of Castile (his wife being dead), he proclaimed himself king of Castile and Leon, but was defeated at Toro in 1476 by Ferdinand the Catholic, and driven to seek assistance in France. There Louis XI. treacherously held him prisoner till 1479, when he made peace with Ferdinand, and renounced his Spanish pretensions. Joanna took the veil in 1480, and Alfonso was about to enter a monastery when he died of the plague. He founded at Coimbra the first library in Portugal. For his zeal in ransoming Christian slaves he was called "the redeemer of captives."

ALFORD, Henry, an English author and clergyman, born in London in 1810, died Jan. 12, 1871. He was educated at Ilminster, and at Trinity college, Cambridge. In 1833 he was appointed curate of Ampton, Suffolk, and soon afterward vicar of Wymeswold, Leicestershire, where he spent 18 years. He was a fellow of his college, and from 1841 to 1857 was examiner of logic and moral philosophy in the university of London. During the years 1841 and 1842 he was also Inlusean lecturer at Cambridge. On leaving Leicestershire he became minister of Quebec street chapel (1853), where he was distinguished as an eloquent preacher. In 1857, upon the death of Dean Lyall, Lord Palmerston appointed him dean of Canterbury. He wrote poetry in the early part of his life, publishing among other volumes "The School of the Heart and other Poems" (Cambridge, 1835), of which several editions have since appeared. Didaetic and defective in form, many of his poems are nevertheless regarded as gems of exquisite thought and religious feeling. Among his other works are his "Plea for the Queen's English" (1836), and "How to Study the New Testament" (1867). But he will be best remembered by his edition of the Greek Testament with English notes, referenc-

ees, critical commentary, &c. (5 vols., 1841-'61; new and abridged edition by B. H. Alford, 1869); and by "The New Testament for English Readers," consisting of the authorized version, with notes, marginal references, and commentary (4 vols. 8vo, revised ed., 1867).

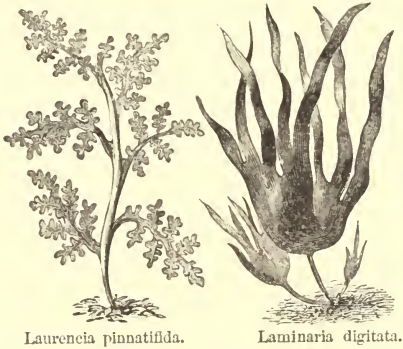

ALFORT, a village of France, department of Seine, 5 m. S. E. of Paris, on the Marne, opposite Charenton, forming with the village of Maisons the commune of Maisons-Alfort; pop. 2,500. It is the seat of a famous national veterinary school established by Bourgelat in 1766, having courses of instruction in anatomy, botany, pharmacy, and the diseases and training of animals, a library of zoological works, laboratories, a pharmacy, a botanic garden, rich cabinets of specimens, a collection of living animals, and a sheepfold in which merino sheep are raised for the improvement of breeds. A certain number of scholars are admitted at the national expense, and others pay their own fees. The course of study lasts eight years.

ALFRED THE GREAT, king of the West Saxons, born at Wantage in Berkshire in 849, died probably in 901 (Oct. 26 or 28). He was the fifth and youngest son of Ethelwolf, king of the West Saxons, and seems to have been his favorite child. He was sent in his fifth year to Rome, where Leo IV. (according to the Saxon chronicles) "consecrated him king." However, the throne was first occupied by three of his brothers in succession. In the reign of Ethelred, the last of them, an unusually formidable invasion of the Danes occurred, and Ethelred was slain (871). Alfred, who had been his brother's most efficient general, was thereupon, at the age of 22, declared king by the earls and chiefs, with the consent of the whole nation. He succeeded in making a temporary peace with the invaders, which left them free to overrun the other provinces of the island. This truce lasted till 876. Alfred, meanwhile, finding it impossible to raise an army able to cope with them in the field, fitted out a naval force, with which on the commencement of hostilities he worsted them in several engagements, and in the spring of 877, according to Asser, drove 120 Danish ships on shore, causing the destruction of all on board. The next January they invaded the kingdom in greater numbers than ever. The king, with a few followers, sought safety in the woods and among the hills, and for a few months found shelter in the hut of a cowherd at Athelney, a secluded spot surrounded by marshes and accessible only by a single bridge. Here after a while he was joined by a band of fighting men, and, fortifying his position, made occasional inroads upon the possessions of the enemy. In May, 878, having been joined by an armed body of his subjects, he attacked the main army of Danes at Eddington, and routed them with great slaughter. It was on the day before this battle that he is said to have entered the enemy's camp disguised as a harper. The defeated king Godrun or Guthrun and his followers

were made to embrace Christianity, and received the modern counties of Norfolk, Suffolk, and Cambridge as a place of residence. They became the subjects of Alfred, who in the course of six years seems to have made himself the virtual ruler of all England, though never formally recognized as such. His conduct before his misfortunes seems to have been haughty and selfish; but after his restoration his rule was wise and beneficent. The few years of tranquillity from 886 to 893 were employed by him in restoring the cities and fortresses which had been destroyed during the war, improving the navy, of which he is esteemed the founder, systematizing the laws, and in literary labors. The last invasion of the Northmen in his reign took place in 894, under a leader named Hastings, and after a struggle which lasted three years, of which every part of the country was in turn the theatre, they were once more driven out. He established an elaborate system of coast defences, erecting some 50 fortresses at various points, and regulated the military service so as to keep only one half the population capable of bearing arms in the field at a time, leaving the remainder to cultivate the soil. It is probable that the code of laws which bears his name is chiefly compiled from the enactments of his predecessors. He made great improvements in the administration of justice, caused the rights of property to be respected, and made great efforts for the advancement of literature and education. Although he is said to have been 12 years of age before he was taught the alphabet, he afterward became possessed of extraordinary learning. He invited literary men to his court from all parts of Europe, and although the prevailing tradition that he founded the university of Oxford is doubtful, he certainly did much for the improvement of the monastic school which had previously existed in that place. He made numerous translations from the Latin of works which he considered adapted to the wants of his countrymen, among which are the *Liber Pastoralis Cura* of Pope Gregory the Great, Boethius's *De Consolatione Philosophiæ*, and Bede's "History of England." He married Elswith, the daughter of a Mercian nobleman, by whom he is said to have had four sons. His disposition was gentle and amiable, and his bearing frank and affable toward all. He was merciful and forgiving toward his enemies. His health was never good; in his youth he suffered from piles; and at the age of 20 he was attacked by an undetermined internal disease causing terrible pangs, which he bore with stoical serenity, never suffering his labors to be interrupted.

ALGÆ, a large family of cellular flowerless plants, in which there is a complete series of forms, from plants of merely one or two cells to most complicated and extensive growths, as seen in many seaweeds. Algæ live for the most part entirely in water, fresh, salt, or brackish, and take their food by their whole surface from the medium in which they grow.

A convenient classification divides them into five orders, *diatomaceæ*, *confervaceæ*, *fucaeæ*, *ceramiaceæ*, and *characeæ*.—The diatoms are

Laurencia pinnatifida.

Laminaria digitata.

microscopic bodies, having a spontaneous movement through the water in which they live, and siliceous skeletons or frames, often of wonderful beauty, which accumulate in vast deposits at the bottom of ponds. (See DIATOMACEÆ.)—The confervas are plants of simple cells or series of cells, commonly found in fresh water, but also in salt, growing with great rapidity, and forming a green, red, or violet scum on water, or stain on snow or moist stones. The red snow (*protococcus nivalis*) consists of a single cell, which subdivides into other cells forming new individuals, so that in a few hours a large extent of snow may be covered by this plant, which is only visible by its conglomeration. A similar plant often colors many square miles of the sea, and, according to some, has given the Red sea its name. Many fresh-water confervas appear in early spring, and when examined by the microscope are shown to be delicate threads composed of a single line of transparent cells of varied shapes, containing several forms of greenish nuclei; these are the reproductive particles which are to form the spores. The star jelly (nostoc) springs up suddenly after a rain as a greenish trembling jelly. Lavers (*porphyra* and *ulva*) are stewed and eaten in Europe, and the *ulva compressa* by the Hawaiian Islanders. Several confervas have been found growing in hot springs of an elevated temperature; as at the geysers in California, in a spring of a temperature of 120° F. (W. T. Brigham).—The *fucaeæ* or seaweeds, when found in fresh water, much resemble confervas, but are distinguished from all other algae by the position of the spores in cells or receptacles sunk in the substance of the plant and opening at the surface by a small pore. The sea aprons (*laminaria*) have broad flattened fronds attached to a cylindrical stem, which holds the plant during growth fastened to rocky bottoms; when torn off by waves, they are found floating, and sometimes of a length of several hundred feet. The *laminaria saccharina* is eaten in Japan, and the *laminaria digitata* (called "tangle") in Scotland.

Bory de St. Vincent describes an alga of this family which attains a length of 25 or 30 feet, and the trunk is often as thick as a man's thigh. The *sargassum* or gulf weed forms immense beds in the Atlantic, covering 40,000 square miles. The bladder-weed (*fucus vesiculosus*) is common on rocky coasts in temperate regions, and is easily recognized by its olive-green, strap-shaped, branching divisions, bearing at small intervals air bladders by means of which its free end floats in the rising tide. This fucus is used for manure, and also for the manufacture of kelp, and, with other algae, as a source of iodine. A nutritious gelatine is secreted by many of the fuci, and they are eaten by swine or other animals in times of scarcity, and even by man. Perhaps the most remarkable fucus is the *hydrograstrum*, described by Endlicher as a branching plant, imitating the root, stem, bud, and fruit of the higher plants, but all composed of a single branching cell.—The fourth order, or *ceramiaceæ* (rose tangles), comprises seaweeds of a rose or purplish color, seldom olive or violet; the spores are grouped in fours or threes. The order is distinguished also for the amount of gelatine many of its species contain, rendering them most useful among seaweeds. Carrageen moss (*chondrus crispus*) is used in place

Chondrus crispus.

Fucus vesiculosus.

of Iceland moss (a lichen, *cestraria Islandica*), and its bitter flavor is partly removed by steeping in fresh water for some time before boiling; it then takes the place of isinglass in preparing jellies and blanc-mange. Dulse (*iridea edulis*) is a thin purplish seaweed, which is eaten, as well as another alga, *rhodomenia palmata*, by the Scotch and Irish, who call it dillesk, and the Icelanders, who name it sugar seaweed; within a few years it has become an article of food among the foreign population of Boston, and is sold in the streets. The East Indian swallows are said to construct the edible birds' nests from the *gelidium*, a genus of this order. The *plocaria tenax* (*glæpeltis*) furnishes so much good gelatine that it is an important article of commerce among the Chinese, many tons being annually imported at Canton for the preparation of glue and varnish for lanterns, windows, and paper umbrellas,

also to give a gloss to silks and to size paper; windows are frequently made of strips of bamboo coated with this glue. As objects of beauty this order affords many fine species, as the *laurencia pinatifida*, shown in the first cut.—The *characeæ* are aquatic plants of a more obscure organization than any of the previous orders; they usually exhale a fetid odor, supposed to be unwholesome, and are curious as exhibiting under the microscope a circulation in their transparent stems and branches.—*Reproduction of the algæ.* There are four principal ways in which algæ may produce new individuals. 1. A direct action is exercised by formations playing the part of male organs upon a minute mass of protoplasm, which before this action has no coating of cellulose, but now acquires this and becomes a spore. This male organ is analogous to the anther of flowering plants, and is hence called antheridium; but while the anther produces pollen, the antheridium gives birth to little bodies of a very different nature, which have the power of locomotion by means of vibratile cilia and closely resemble animalcules; these are called antherozoids. An example of this method is seen in *vaucheria*, an alga consisting of green, one-celled filaments, common in ditches. The antheridium develops from the side of one of these filaments as a horn-like projection, and is soon followed by a similar exerescence in its immediate neighborhood called the sporangium; these are at first continuous with the tube on which they grow, but finally form a partition completely separating their contents from the parent plant. The antheridium then opens, discharging the antherozoids, which move at once toward the opening end of the sporangium, and are met by a layer of mucilage, into which they thrust themselves and then retire, repeating this curious action for half an hour, until a thin membrane appears across the opening, due doubtless to the penetration of an antherozoid; and then the others move more and more slowly, and at last become quite still. The fecundated sporangium when grown detaches itself from the plant as a cell filled with brownish particles. After three months it recovers its green color and elongates into a tubular filament of the perfect alga. 2. The same *vaucheria* often shows the extremity of its filament swollen into a club shape, and the green matter is condensed there until it assumes a blackish tint and becomes enclosed in its own membrane. The end of the filament bursts and permits the escape of a zoöspore, which is covered with vibratile cilia having so rapid a motion that to make them visible it is necessary to retard the motion by opium, or arrest it entirely by a very weak solution of iodine. The zoöspores, produced apparently without the intervention of sexes, move through the water for some time, and when the cilia cease to vibrate soon germinate. 3. The ordinary fucus presents in its substance cavities or conceptacles opening when mature

by small pores, through which escape, in the female plants, the sporangia, which contain eight spores in a membrane which soon dissolves, setting free in the water the spores, and in the male plants the antheridia, which also burst and discharge antherozoids, which are small bodies with two long cilia. The antherozoids meet the spores, which seem simply mucilaginous globules, and attaching themselves impart to the spores a rapid rotary motion, lasting usually six or eight minutes. The spore immediately becomes covered with a membrane, and is ready to germinate as a new fucus. 4. Reproduction by conjugation is seen in the fresh-water alga *spirogyra*, which is common in stagnant water in the early spring. The slender filaments of which it is composed are divided into cells by transverse partitions, and these cells contain gelatinous endochrome. Two adjacent filaments conjugate on contact, two cells swelling toward each other and finally uniting, when the contents of one are transferred to the other, and the communication is closed and the full cell develops a spore. The spores are formed sometimes in one filament, sometimes in the other, and when mature break away the cells and elongate into new spirogyras. This process may be seen with a microscope of low power, and so short is the time occupied that it may be easily followed from beginning to end.—Like higher plants, algæ absorb carbonic acid and exhale oxygen in sunlight, although they are not so dependent on the sun for their bright colors, these existing at depths where the light would be less than half a candle. Professor Harvey has adopted a classification from the color of the spores, which is often used as exceedingly convenient, into chlorosperms, with green spores and usually with a greenish color over all the plant; rhodosperms, with rose-colored spores; melanosperms, with olive-brown spores. From the motive powers of the zoöspores of algæ, it is not strange that the early microscopists should have confounded the animal and vegetable kingdoms, which come so close together in the spores of algæ and the lowest of animals.

ALGARDI, Alessandro, an Italian sculptor, born in Bologna about the year 1600, died in 1654. Domenichino obtained employment for him at Rome. By a statue of St. Philip Neri in the sacristy of the Oratorian church in that city, and a colossal group representing the decapitation of St. Paul in the church of the Barnabites at Bologna, he achieved a reputation as the first sculptor of his time. He was chosen to execute the bronze statue of Innocent X., erected to commemorate the completion of the capitol at Rome. He produced the monument of Leo XI. in St. Peter's; and for one of the altars in the same church he made the largest basso-relievo in the world—a work in marble representing Attila checked by St. Leo.

ALGAROTTI, Francesco, an Italian scholar, born in Venice, Dec. 11, 1712, died in Leghorn, March 3, 1764. After studying in Rome

and Bologna, he visited France and England, and in Paris wrote "Newtonianism for Ladies" (*Newtonianismo per le dame*, 1734). He then went to Russia with Lord Baltimore, and published an account of the country, and in Germany became acquainted with Frederick, then crown prince of Prussia, one of whose first acts on coming to the throne was to invite Algarotti to his court. Henceforth the Italian lived in close intercourse with the king. He was created a count, appointed chamberlain, employed occasionally in diplomatic affairs, and commissioned by the elector of Saxony to collect works of art for the Dresden gallery.

ALGAROVILLA, an astringent substance, produced by the tree *juga Martha*, an acacia, found at Santa Marta in New Granada. The portions taken to England, and examined by Dr. Ure, were pods bruised and agglutinated with the extractive exudation of the seeds and husks. It is replete with tannin, and for tanning leather possesses more than four times the strength of good oak bark. It is also well adapted for the manufacture of black ink, for a yellow dye, and for an astringent medicine.

ALGARVE, the southernmost province of Portugal, bounded by Alemtejo, Spain, and the Atlantic; area, 1,872 sq. m.; pop. in 1868, 177,342. It is watered by several small rivers and by the Guadiana, which divides it from Spain. A considerable mountain range in the north forms a watershed between it and Alemtejo. The S. W. part of the province is mountainous and rocky, and of wild and dreary aspect. The plains and valleys produce fruits in abundance, among them dates, figs, almonds, and oranges, which, with wines and fish, form the chief exports. The principal towns are Faro, the capital, Tavira, and Lagos, all on the S. coast, which ends in Cape St. Vincent, the S. W. extremity of Europe.—Algarve originally extended over much of S. Spain, and also included a portion of N. W. Africa, where the name is still retained by a province of Morocco (*El Gharbie*, the western land). It constituted a Moorish kingdom till the 13th century, when it was gradually conquered, and the part W. of the Guadiana finally annexed to Portugal as Algarve d'aquem Mar (this side the sea) in 1253. The African portion was conquered by Alfonso V. and formed into the province of Algarve d'alem Mar (beyond the sea) in 1471; and his successors are still called kings of Portugal and the Algarves.

ALGAZZALI, Abu Hamed Mohammed, a Moslem philosopher, born at Tus, Persia, about 1058, died in 1111. His father was a dealer in cotton thread (*gazzal*, whence the name Algazzali), and on his death the son was intrusted to the care of a sufi, or mystical philosopher. He became a professor of theology at Bagdad, and attracted hundreds to his lectures. Anxious to attain to the purest state of which man is capable, he found that for this purpose the soul must be purified from all connection with earth. Accordingly he distributed his wealth,

and sought in Syria, in solitary communion with himself, to attain that ecstatic state for which he longed. He spent some time in this manner, and in travelling, settling at last at Nishapoor, and there he passed the remainder of his days, sometimes, as he says, experiencing the highest bliss of the ecstatic state, but only occasionally, and for a short time. He was a very prolific writer, but his works were not all considered entirely orthodox by the Mohammedans, and one of them was condemned to be burned on account of some strictures on the Mohammedan law. One of his works attained so high a reputation among the Moslems, that they sometimes said, if all Islam were destroyed, it would be but a slight loss provided Algazzali's work on the "Revivification of the Sciences of Religion" were preserved. (See Lewes's "Biographical History of Philosophy.")

ALGEBRA (Arab. *al-jaber*, the science of solution), originally, a kind of higher arithmetic in which the numbers are replaced by symbols; but by later applications the symbols are used as well for geometrical quantities in space, or in mechanics for velocities, distances, and times, so that at present algebra occupies itself with quantities in general, whatever be their nature. The oldest work on this science is that of Diophantus of Alexandria, a Greek writer, who possibly flourished as early as the 4th century, of which the six books that have come down to us do not contain the elements, but the theory of the evolution of powers, and the method of solving undetermined problems. Many problems of this kind were by the ancients considered determined, as they threw out all solutions in irrational quantities. The Brahmans of Hindostan also had a knowledge of algebra, as well as the Arabs; but to whom belongs the priority of the invention it is at present impossible to determine. It is only known that this science was introduced into Christian Europe by the Moors of Spain, a little before the year 1100. For the first three centuries after its introduction it was chiefly studied in Italy, and Lucas Pacioli de Burgo (Luca di Borgo) was the first European writer on the subject. His principal work, *Summa Arithmetica et Geometrica*, was published in Venice in 1494, and republished in 1523. He mentions a Pisan merchant, Leonardo Bonaecio, who lived in the beginning of the 13th century, and learned algebra in travelling among the Arabs along the coast of Africa and in the Levant. Some historians give to him the honor of having introduced this science in Europe, while others, among them Montucla, the great historian of mathematics, mention Paolo de l'Abacco and Belmondo of Padua, who preceded Bonaecio. From the works of Luca di Borgo it appears that in 1500 the science did not go beyond equations of the second degree, the negative solutions were rejected, and the symbols consisted chiefly of abbreviations of words. Great advance was made by Jerome Cardan, who in 1545 published his *Ars Magna*, in which he

gave the solution of equations of the third degree, by an operation which is still known among all mathematicians as the formula of Cardan; those of the fourth degree were solved by his pupil Ludovico Ferrari, and published in the *Ars Magna*, in which also he makes the distinction between positive, negative, and irrational solutions. At the same time Stifelius in Germany invented the signs +, —, and $\sqrt{\quad}$, which did so much to simplify the formulas; he published his *Arithmetica Integra* in Nuremberg in 1544. In 1552 Robert Recorde published in England "The Whetstone of Witte," in which for the first time the sign of equality (=) is introduced. From that time not much progress was made till Vieta in France perfected the algebraic operations and transformations of formulas, and even advanced so far as the general solution of equations of all degrees. He first applied algebra to geometry, and he also found the remarkable expression which solved numerically the problem of the quadrature of the circle. His works were written about the year 1600, but only published long after his death, by Schooten. Among the eminent mathematicians of that time we must also mention Gerard in Flanders, who was the first to indicate the important use of the negative roots of equations in geometrical constructions, while in England Harriot introduced the signs > and <, and Oughtred first wrote the decimal fractions simply by the decimal point, as we do now, without writing the denominator always, as was customary till his time. The 17th century was the most brilliant of all centuries in mathematical discoveries, producing the immortal Descartes, Fermat, Wallis, Galileo, Huyghens, Kepler, Newton, Leibnitz, Bernoulli, and many others not less illustrious; and that century closed with the important discovery of the logarithms and of the differential calculus. The 18th century enriched the vast domain transmitted, and men like Laplace, La Grange, D'Alembert, Maupertuis, Maclaurin, Waring, Lambert, Cutler, Stirling, De Moivre, and above all Euler, developed and perfected all the branches of the science. —The operations of algebra are founded on a mutual agreement concerning signs and symbols. The first letters of the alphabet, *a, b, c*, &c., are used to represent known quantities, whether of space, time, or number, and the last, *z, y, x*, &c., are used for the unknown quantities. They are connected by the signs +, —, \times , and \div , meaning respectively addition, subtraction, multiplication, and division. The powers of quantities are expressed by superior numbers, as a^2 for $a \times a$, a^5 for $a \times a \times a \times a \times a$; the roots by the sign $\sqrt{\quad}$, or $\sqrt[3]{\quad}$, &c. The small space in which a long operation can be indicated by these signs may be illustrated by the following algebraic expression:

$$\frac{17a \times (c-d)^2 + c^3 \times \sqrt{(a^2-b^2)} - a \times c}{\sqrt{(b \times c)} - (a-b) \times (c-d) + ac} + \frac{\sqrt{3ab}}{8a^5}$$

which is an ordinary expression involving so

many operations that to describe them clearly would occupy a whole page.

ALGECIRAS, a seaport and town of Spain, in Andalusia, province of Cadiz, on the W. side of Gibraltar bay, opposite and 6 m. W. of Gibraltar; pop. 18,000. Charles III. rebuilt it in 1760, as a point of annoyance against Gibraltar. It is constructed of stone, and presents a fair appearance compared with many of the small Spanish towns. The port is guarded by a battery called the Fuerte de Santiago. The town is supplied with water conveyed by an aqueduct over the Miel. The principal trade is the export of coal from the neighboring mountains, charcoal, and leather. Two considerable sea fights took place off Algeciras in July, 1801, between the English and French squadrons, and in the second the English were victorious.

ALGERBA, the third star in the constellation of Leo. It is a noted star among astronomers, being used as a test for telescopes, which prove it to be double. One of its constituents is orange, the other green.

ALGER, Horatio, Jr., an American author, born at Revere, near Boston, Mass., Jan. 13, 1834. He graduated at Harvard college in 1852, and was afterward engaged partly in teaching and partly in writing, being for a time editorially connected with two Boston newspapers. He then spent a year in travel in Europe, corresponding with American papers. Upon his return he resumed teaching and writing. In 1866 he took up his residence in New York, where he became deeply interested in the condition of the street boys. This has given form to most of his later writings. Prominent among these are the "Raggen Dick" series and the "Tattered Tom" series. With the exception of "Helen Ford, a Novel," and various magazine papers, Mr. Alger's writings belong mainly to the class of books for the young.

ALGER, William Rounseville, an American clergyman and author, cousin of the preceding, born at Freetown, Mass., in 1823. He graduated at Harvard college in 1847, studied for the ministry, and became pastor of a Unitarian church in Roxbury. In 1855 he removed to Boston, where he succeeded Theodore Parker as minister of the "Liberal Christians" who worship in Music Hall, Boston, where he still continues to preach (1873). His works comprise "The Poetry of the Orient, or Metrical Specimens of the Thought, Sentiment, and Fancy of the East" (1856); "A Critical History of the Doctrine of a Future Life" (1861); "The Genius of Solitude, or the Loneliness of Human Life" (1867); and "Friendships of Women" (1870).

ALGERIA, a division of N. Africa, formerly the Turkish pashalic of Algiers, but since 1831 included in the foreign dominions of France, bounded N. by the Mediterranean, E. by Tunis, W. by Morocco, S. by the Great Sahara. It is, in the main, situated between lat. 32° and 37° N., and lon. 2° W. and 9° E. The bounda-

ries are not well defined, as large portions of the border districts are claimed both by the French government and the nomadic tribes which inhabit them. An official statement in 1850 estimated the area at 150,568 sq. m., distributed as follows among the three provinces: Algiers, 43,627 sq. m.; Oran, 39,375; Constantine, 67,566. Later unofficial calculations make it as high as 258,317 sq. m. (Algiers, 39,120; Oran, 111,831; Constantine, 107,366). The Atlas mountains constitute an important physical feature in the country. The Little Atlas runs along the rocky coast, and varies from 3,000 to near 7,000 ft. in height; while in the south the Greater Atlas reaches, or even exceeds, in some points an elevation of 8,000 ft. Between the Little and the Greater Atlas extends a plateau called the Tell (highlands), varying in height from 1,900 to 3,600 ft., and containing a large number of salt lakes, which dry up during the summer months. Long, winding defiles lead S. from the Greater Atlas into the Algerian Sahara. This desert, occupying more than half

large portion of the country is healthy, even for Europeans; but in the marshy districts the foreign-born population generally succumb to fevers. Ophthalmia and cutaneous diseases are common. On the limits of the desert the soil is arid and sandy, but between the mountain districts it is fertile, and especially so in the neighborhood of the streams. Grain crops of all kinds, European and tropical fruits, flowers, and particularly roses, of remarkable beauty, and a species of sugar cane, said to be the largest and most productive of any known species, grow in Algeria. Domestic animals of every variety are numerous. The horses are excellent; the asses are of fine growth and much used for riding. The camel and dromedary of Algeria are very superior. The merino sheep is indigenous. The Numidian lion, the panther and leopard, ostriches, serpents, scorpions, and many venomous reptiles are abundant.—The chief towns are Algiers, the capital (pop. in 1866, 52,614), Constantine (35,417), and Oran (34,058). Near Bona, on the north-eastern coast, are the coral fisheries, frequented by the fishers from France and Italy. Boughiah is on the gulf of the same name. On the coast, between Algiers and Oran, are Koléah, Cherrhell (the ancient Caesarea, the residence of Juba), and Mostaganem. Tlemcen, once the residence of Abd-el-Kader, is situated in a fertile country, near the Moroccan border; the ancient city was destroyed by fire in 1670, and the modern town was almost destroyed by the French. Other towns of the interior are Blidah, Médéah, and Milianah, S. and S. W. of the capital. South of the Greater Atlas is the Zaab, the ancient Gætulia. The chief place is Biscara; the Biscareens are a peaceful race, much liked in the northern ports as servants and porters. There are many remains of antiquity in the interior, especially in the province of Constantine, among others those of the ancient city of Lambessa, with remains of the city gates, part of an amphitheatre, and a mausoleum supported by Corinthian pillars.—The total population in 1866 was 2,921,246, of whom 217,990 were of European descent. Among the latter there were 122,119 Frenchmen, 58,510 Spaniards, 16,655 Italians, 10,627 Maltese, 5,436 Germans, and 4,643 of other nationalities; 72,508 were born in Algeria. In 1831 the European population was 3,228; in 1836, 14,560; in 1841, 35,727; in 1846, 99,801; in 1851, 131,283; in 1856, 159,282; in 1861, 192,746. The number of Mohammedans living in the territory subject to civil government in 1870 was 225,693; nomads, 2,434,974; native Jews, 33,117. A comparison of the above figures with former censuses shows a decrease of the native population, while the Europeans slowly increase. The great efforts made by the government to promote colonization induced from 1830 to 1855 about one million Europeans to emigrate to Algeria; but the majority either returned after a short time or succumbed to the climate. From 1830 to

the country, contains many fertile oases and the large salt lake of Melrir, which receives a number of small rivers. The number of oases has been increased by means of artesian wells dug by order of the French government. The principal plain of the country, that of Metidjah, belongs to the region of the Little Atlas. The Greater Atlas forms the watershed of the country. The principal river is the Shelliff, which has a tortuous course of about 200 m. and flows into the Mediterranean. The rivers which flow from the S. side of the Greater Atlas lose themselves in the desert, and none are navigable. They are nearly dried up in the summer, but overflow a considerable extent of country in the spring and fertilize the soil.—The climate is generally warm, but the heat is rarely oppressive except under the prevalence of the simoom or hot wind from the Sahara, when the temperature ranges as high as 110°. A

1851 the number of deaths (60,678) exceeded the births (44,900) by 16,000. Among the children of the Europeans the mortality is even greater than among the adults. The Moorish population in the cities is likewise decreasing; only the Jews show a steady increase. The general result of the efforts for colonization is trifling. From 1831 to 1866 the government had ceded to European settlers no more than 222,269 hectares. For several years the number of Europeans leaving the country was almost as large as the number of new arrivals. Thus in 1856, 30,460 returned to Europe, and only 39,239 arrived. The republican government hoped for an improvement of this state of affairs from a limitation of the military and an enlargement of the civil authority of the country; and in order to induce the malcontent inhabitants of the districts ceded in 1871 to Germany to emigrate to Algeria, it placed by a decree of June 21, 1871, 100,000 hectares of the best government lands at their disposal. The Berbers or Kabyles, who call themselves Mazidh (noble), are believed to have been the aboriginal inhabitants, the Numidians and Gætulians of antiquity. Arabs, the descendants of the Mussulman invaders, Moors, Turks, Kulughs, Jews, and negroes, and lastly the French and other European Christians, form the rest of the population. The Kabyles are an industrious race, living in regular villages, excellent cultivators, and working in mines, in metals, and in coarse woollen and cotton factories. They make gunpowder and soap, gather honey and wax, and supply the towns with poultry, fruit, and other provisions. The Arabs follow a nomadic life, shifting their camps from place to place. The Moors are probably the least respectable of the inhabitants. Living in the towns, and more luxurious than either the Arabs or Kabyles, they are, from the constant oppression of their Turkish rulers, a timid race, reserving nevertheless their cruelty and vindictiveness, while in moral character they stand very low. The nomads live in tents; other tribes inhabit dwellings of somewhat greater stability called *gourbis*; only a few have houses. The proportion of the three classes in 1857 is shown by the following table:

PROVINCES.	Mountain Kabyles.	Kabyles of the Plain.	Arabs.	Tents.	Gourbis.	Houses.
Algiers.....	250,474	27,800	447,752	55,529	65,537	39,881
Oran.....	22,119	45,362	431,485	77,389	6,986	8,772
Constantine.	277,135	305,691	506,195	111,151	63,405	31,327
Total....	550,428	378,953	1,385,432	244,009	136,228	79,480

—The census of 1866 returned 211,195 Catholics, 5,002 Protestants, 33,952 native Jews, 1,785 European Jews, 17,232 members of other Christian sects or persons of unknown religion, and 2,652,072 Mohammedans. For the Catholics a bishopric was erected at Algiers in 1838, which in 1867 was raised to an archbishopric;

in the same year the new dioceses of Oran and Constantine were created. For the Protestants a decree of 1857 created consistories at Algiers, Oran, and Constantine, under which both the Lutheran and the Reformed churches are placed. The religious affairs of the Mohammedan population are placed under the mufits of the two principal mosques at Algiers. The number of free public schools in 1866 was 426, with 45,375 pupils. For secondary instruction there were lycées at Algiers, Bona, Constantine, Philippeville, and Oran, the secondary institutions at Tlemcen, and the free school of Oran. The system of public instruction for the Mohammedans comprised the *douar* schools, the law schools (*zaïouas*), the schools of law and literature (*medresas*), the French-Arabic schools, and the French-Arabic colleges. The French troops in Algeria consisted in 1866 of 67,774 men. Besides the garrison troops, which after a certain number of years return to France, there are the so-called native troops, which do not leave the colony except in time of war, and consist of three regiments of Turcos, three of zouaves, three of chasseurs d'Afrique, and three of spalis; altogether 15,000 infantry and 3,000 horse.—The administration of Algeria was in 1859 placed under a special ministry, which was abolished by decree of Dec. 11, 1860. It was then placed in the hands of a military governor general, to whom all civil as well as military authorities were subordinate. The republic, established in 1870, placed at the head of the administration a civil governor, who convokes annually for the establishment of the budget a council, consisting of the three prefects, the archbishop, the military commander, and other notables. Algeria also received the right to send six deputies to the national assembly. At the head of each of the three provinces is a prefect.—The revenue of Algeria in 1866 amounted to 42,223,000 francs, and the expenditure to 47,470,000. The French budget provides in addition for the maintenance of the army, for public works, and for many other expenditures. In the budget of ordinary and extraordinary expenditures of 1871, the expenditure for Algeria is set down at 22,691,925 francs. According to a statement made by Picard in the legislative body in 1854, Algeria at that time had cost France about three milliards of francs and the lives of 150,000 soldiers. In 1868 the government made an agreement with the *société générale algérienne* for a loan of 100,000,000 francs, which is gradually to be used for the general improvement of the country. The imports in 1868 were valued at 192,664,360 francs, and the exports at 103,069,304. The chief articles of import in that year were cotton cloth, woollens, leather and leather goods, wine, brandy, and spirits, fresh fruit, sawed timber, and materials for building. The exports included sheep, wool, tallow, hides, coral, iron, fibre, reeds, cork, olive oil, tobacco, fruit, vegetables, rags, and cotton. In 1870

the most important article of export was esparto for making paper. The movement of shipping in 1867 was as follows :

FLAG.	ENTERED.		CLEARED.	
	Vessels.	Tons.	Vessels.	Tons.
French	527	121,010	659	131,331
Foreign	1,714	164,285	1,625	149,192
Total	2,241	285,295	2,284	280,523

The merchant navy of Algeria, on Dec. 31, 1868, consisted of 147 sailing vessels, of 4,098 tons. A decree of July 11, 1860, gave to a company, at the head of which were Count Branicky and the banker Gautier, a charter of 99 years for the construction of a number of important railroad lines; but in 1870 only one of them, that from Constantine to the sea, was near its completion. The telegraphic connection of Algeria with France was established in July, 1870, by a submarine cable between Bona and Marseilles.—The earliest inhabitants of Algeria of whom we have any trustworthy accounts were the Numidians and the Moors (Mauri). The former lived in the mountain districts of the east, and the Moors in the west, where they established many flourishing coast towns, which carried on a brisk trade with Europe. The conquest of Carthage in 146 B. C. laid the foundation of the rule of the Romans in this part of Africa, which was gradually extended over the whole of the present Algeria. The eastern district at first constituted a portion of the province of Africa, but from the time of Constantine the Great it formed the province of Numidia, and the western district became the province of Mauritania Cæsariensis. The whole country attained a high degree of prosperity. As a defence against the savage mountain tribes the Romans built several forts, one of which, Guelma, is still extant. In the early part of the 5th century the country was conquered by the Vandals, in whose possession it remained till 534, when Belisarius subjected it to the Byzantine empire. The Arabs about 160 years later advanced into the mountains of the Numidians. The Christian religion, which had early been introduced into the country, was wholly extinguished by the Mohammedan conquerors; but the people partially recovered from the state of barbarism into which they had relapsed under the rule of the Vandals. After belonging for a time to the dominions of the Ommyade caliphs, Algeria became an independent Moorish state, under the dynasty of the Zereides, which ruled it from 970 to 1148, when Roger of Sicily conquered northern Africa. A few years later (1159) the Almohades of Morocco obtained possession of Algeria and ruled there till 1269, when they were expelled by the Zianides of Fez. This dynasty became at the close of the 15th century involved in protracted conflicts with the Spaniards, especially when about 20,000 families of Moors and Jews, who in 1492 had been expelled from Spain, settled in Algeria and sought revenge in piracy. In

1506 the Spaniards took Bona, and in 1509 the capture of Oran by Cardinal Ximenes, and of the city of Algiers itself, completed the subjection of nearly the entire province. The Spaniards erected fortifications at Algiers, but shortly before the death of King Ferdinand in 1516 the emir of Metidja called to his aid the pirate Horuk Barbarossa. This chief expelled the Spaniards from Algiers, murdered the emir, and made himself ruler of the city and its territory. Soon afterward he conquered Tenez and Tlemcen. The Spaniards defeated him in 1517, and in 1518 put him to death. His brother and successor Khair-ed-Din sought assistance from the sultan Selim I., and acknowledged that prince as his sovereign. Selim appointed him pasha of Algiers, and sent him a body of troops with which he repulsed the Spaniards and made himself master of the country. Charles V. made an attempt to reinstate the Spanish authority, and a powerful expedition of 370 vessels and 30,000 men crossed the Mediterranean in 1541; but a storm and earthquake dispersed the fleet, and cut off all communication between it and the army. The troops made their escape with a loss of 8,000 men, 15 vessels of war, and 140 transports. From this time forward there were unceasing hostilities between the Barbary powers and the knights of Malta; thence sprang that system of piracy which made the Algerine corsairs so terrible in the Mediterranean. On the other hand, the boundaries of Algeria were constantly extended in the wars with the neighboring tribes. Before the close of the 16th century the pasha of Algeria had advanced westward as far as the frontier of Morocco. Oran, however, remained in the hands of the Spaniards till 1708. Bugia in the east was conquered in 1554, and in the south the territory of Algeria was extended as far as the desert. Several attempts made by the Spaniards to reconquer the western provinces utterly failed. In 1561 an entire Spanish army was annihilated at Mostaganem, the Algerines capturing 12,000 men. The duke of Beaufort in 1663 and subsequent years gained several successes, but they had no permanent results. The English under Blake (1655), the French under Duquesne (1682 and 1683), the Dutch, and other powers, at various times attacked Algiers; and Duquesne twice bombarded it. Thousands of Christian slaves constantly languished in captivity in Algiers; and societies of pious men were formed, whose express object was to ransom the prisoners. Meanwhile the authority of the Turkish government had been reduced to a name. The janizaries from 1600 elected their deys, and these finally declared their independence of the Porte. The last Turkish pasha was expelled by Dey Ibrahim in 1705; and the janizaries by tumultuous elections appointed new chiefs, whom in their mutinies they often murdered. The janizaries were recruited from the immigrants from Turkey, no native, though the son of a janizary by a woman of the country, being

admitted into their ranks. The dey sent occasional presents to Constantinople as a token of his nominal allegiance; but all regular tribute was withdrawn, and the Turks, hampered by their constant struggles with Russia, were too weak to chastise the rebels of a distant province. In 1775 Spain undertook her last great expedition against Algiers. The fleet consisted of 44 war vessels and 340 transports under Admiral Castéjon, and the army, which was under the command of Gen. O'Reilly, of 25,000 men. Like all the former expeditions, it was utterly unsuccessful. The weaker Christian powers, like Naples, Denmark, Sweden, and the Hanse towns, submitted to the annual payment of a tribute, which nevertheless did not always protect their vessels. England remained inactive because the insecurity of the Mediterranean injured the commerce of other powers more than her own. During the French revolution and the empire, the presence of large fleets in the Mediterranean put a check to the piracies. On the renewal of peace, however, the Algerines recommenced their depredations; but now the Americans, who in 1795 had been compelled to follow the example of European nations, and to subsidize the dey for peace, refused the tribute. In June, 1815, Commodore Decatur encountered an Algerine squadron near Cartagena, took a frigate and a brig, and sailed into the bay of Algiers, where he forced the dey to surrender all American prisoners, and to abandon all future claims for tribute. This bold example was followed by the English, who, under Lord Exmouth, bombarded the city in 1816, and reduced it to ashes, compelling the dey to surrender his prisoners. Piracy, however, was not suppressed, and in 1826 the Algerines openly seized Italian vessels in the Mediterranean, and even carried their incursions into the North sea. Meanwhile a serious quarrel had broken out with France. In 1823 the dwelling of the French consul had been plundered; the Algerine ruler, Hussein Bey, personally insulted the consul and spoke disrespectfully of the French king; and various outrages were committed on French vessels. Algiers was blockaded, and negotiations were opened between France, Mehemet Ali, and the Porte, by which Mehemet Ali, with the assistance of France, undertook to conquer Algiers, and to pay a regular tribute to the sultan. This was broken off, and the government of Charles X. at last sent an expedition against Algiers in June, 1830, consisting of 38,000 men and 4,000 horses, under command of Gen. Bourmont. Algiers capitulated July 4, on condition that private property and the religion of the country should be respected, and that the dey and his Turks should retire. The French took 17 ships of war, 1,500 bronze cannon, and nearly \$10,000,000 in specie. They immediately garrisoned Algiers, and established a military regency. Small squadrons sailed to Tunis and Tripoli, and concluded treaties with these states, which put an end to piracy. Gen. Bour-

mont was made a marshal, and within a short time captured Bona, Oran, and Bugia. The French intended to surrender Algiers to the sultan, and instructions to that effect were actually on their way to Constantinople when Charles X. was dethroned, and Louis Philippe decided to retain the conquest. Clausel was sent over as general-in-chief in place of Bourmont. As the Turkish soldiers, who had thus far ruled Algeria, were driven out of the country, the Arab and Kabyle tribes soon rose against the new rulers. Each town had to be captured in detail at an immense sacrifice of life. The Marabouts preached a holy war against the Christian conquerors, and the insurgents found an able chief in the young emir Abd-el-Kader. Clausel was replaced by Berthezène, and the latter by Lieut. Gen. Savary, duke of Rovigo, in the course of 1831. In carrying on the war against the natives Savary committed the most treacherous acts. The whole Arab tribe El-Uffia, including the old men, women, and children, were massacred in one night on account of a robbery committed by some members of the tribe. In consequence of such cruelties the entire nation again flew to arms, under the lead of Abd-el-Kader, who maintained the struggle through the reign of Louis Philippe. (See *ABD-EL-KADER*.) In December, 1847, he surrendered to Gen. Lamoricière. The war against Abd-el-Kader thus closed had been signalized on the part of the French by many cruelties, none of which produced so painful a sensation as an act of Col. Péllissier, in 1845, in smothering several hundred Arabs in a cavern. The next notable insurrection was that of the fanatical Marabout Si-Bon-Zian, who in 1849 raised a rebellion among the mountain tribes, but was finally pursued by the French to the oasis of Zaatsha, where he perished (Nov. 26), with the entire population of his last stronghold. Gen. St. Arnaud in 1851, and Marshal Randon in 1857, fought with success against the Kabyles.—The administration of Algeria underwent a considerable change by the imperial decrees of 1858, which abolished the office of governor general, and appointed Prince Napoleon chief of a special ministry for Algerian affairs. The civil districts were more strictly separated from the military territory, and general councils introduced. But after a trial of only two years, the government was regarded as a failure; the Algerian ministry was abolished, and Marshal Péllissier reappointed to the office of governor general, which he had previously filled for a few months in 1851. One of the greatest benefits which the French rule has conferred upon both colonists and natives is the successful boring of a number of artesian wells in the desert, the first of which was begun in 1856. In February, 1863, Napoleon III., in a letter to the governor general, expressed the opinion that Algeria properly was not a French colony, but an Arabic kingdom; that it was wrong to take from the natives any part of their property; that, on the contrary, the tribes and parts of

tribes should be made the owners of the territory they occupied; and that a careful legislation should regulate the conditions of personal property. Though this letter appeared to make some impression upon the minds of the natives, the year 1864 witnessed a new insurrection in the south of Algeria, which was headed by Si-Lala; but at the close of the year the country, of which Gen. MacMahon after the death of Pélissier had been appointed governor general, was again fully pacified. In May, 1865, Napoleon paid a visit to Algeria, and there addressed a proclamation to the population, in which he repeated the sentiments expressed in the letter to Pélissier. From October, 1865, to the beginning of 1867, the French were again harassed by new insurrections under the leadership of Si-Lala and Si-Hamed ben Hamza, who in 1861 had been made a commander of the legion of honor. Si-Hamed, at the head of about 12,000 cavalry, committed great depredations among the tribes friendly to the French rule; but at the beginning of 1867 all the insurgents had either been driven into the Sahara or annihilated. From 1869 to 1870 the colony suffered from famine, locusts, and earthquakes, but was almost free from warfare. After the outbreak of the Franco-German war, the French government in July, 1870, called Governor General MacMahon, and with him the larger portion of the native troops, to the seat of war in France. The news of the disaster at Sedan caused insurrectionary movements in the province of Constantine in September, 1870, and in October in Oran, where the insurgents were joined by some Moroccan tribes; but Gen. Durieu, the successor of MacMahon, succeeded in preventing the troubles from spreading. At the same time the European colonists asked for the aboli-

tion of the military administration; and a civil governor was appointed, under whom three prefects administer the three provinces. Algeria also obtained representation in the national assembly which in February, 1871, met in Bordeaux.—See MacCarthy, *Algeria Romana* (Algiers, 1867); Daumas, *Le Sahara Algérien* (Paris, 1845), *Le grand désert* (2d ed., 1849), and *La Grande Kabylie* (1847); Yusuf (a chief of the Turkish troops in Algeria who joined the French as early as 1832, and subsequently rose to the rank of a general), *Sur les guerres en Afrique* (Algiers); Nettelement, *Histoire de la conquête d'Alger, écrite sur les documents inédits et authentiques* (2d ed., 1871).

ALGHERO, or **Algheri**, a strongly fortified seaport town on the N. W. coast of Sardinia, in the province and 11 m. S. W. of Sassari; pop. 8,000. It was a favorite residence of Charles V. The coral found here is the finest obtained in the Mediterranean.

ALGIERS (Arab. *Al-Jezirah*, the island, because there was originally an island before the city, which has been joined by a mole), a seaport and city of N. Africa, in lat. 36° 47' N., lon. 3° 4' E. It was formerly the capital of a pashalic of the same name, and dependent on the Ottoman empire, but since 1830 has been the capital of the French colony of Algeria. The population, which under the Turks was estimated at 100,000, has since been subject to great fluctuations. In 1838 it was 30,395; in 1846, 70,582; in 1851, 50,111; in 1862, 58,315; in 1866, 52,614; and at present it is estimated at 60,000. Of these, 16,000 are French and 6,000 Jews. The Jews have since the occupation of the country by the French become the most prosperous part of the population, owning most of the land in the city. The natives

Algiers, from the Parade Ground.

manufacture arms, leather, silk stuffs, jewels, &c. The town is built in the form of an amphitheatre, on the N. slope of Mount Boujarin, which rises 500 feet above the bay, and as seen from a distance presents a very imposing and picturesque appearance, heightened by the dazzling whiteness of its houses, which rise in terraces on the side of the hill. In consequence of earthquakes they are seldom built more than one story above the basement. On the summit and overlooking the town stands the Casbah, the castle in which the last dey lived. Its walls are 20 feet thick, and the interior consists of a large courtyard and some four or five stories of porches arched and pillared after the twisted spiral Byzantine order. It also contains several other houses and gardens adorned with sycamores and bananas. The city is enclosed by a wall 30 feet high and 12 thick, with towers and batteries. Each side of the harbor is defended by a strong battery. Many of the streets of Algiers, like those of other Moorish towns, are narrow and tortuous, but in the lower part of the city arcades have been built and the streets widened, giving the place a French aspect. All the streets now have French names. Algiers has a light-house, arsenal, dockyard, many mosques, banks, theatres, fountains, baths, factories, hotels, several synagogues, a handsome cathedral and three other Roman Catholic churches, a Protestant chapel, six colleges, an episcopal seminary, a government house, exchange, bishop's palace, and public library. In 1838 an episcopal see was established in Algiers, which in 1867 was elevated to an archbishopric. It is also the seat of a Protestant consistory, of an academy, a lyceum, an Arabic-French college, a museum, and other literary institutions. The governor general of the French possessions in Africa and other chief functionaries reside here. The port is a sheltered body of water of about 220 acres. It was first formed by Barbarossa in 1530; the French government have spent upon it upward of 20,000,000 francs. In 1862 a railroad was built between Algiers and Blidah, 30 m., and a telegraph cable was laid between Algiers and France. Algiers has become the entrepot of four fifths of the trade of the colony. Steam vessels start for this port from Toulon and Marseilles, and the passage is made in 48 or 50 hours. The commerce between France and Algiers is regarded as a coasting trade and reserved to vessels of French register only. The imports are chiefly coffee, sugar, wine, spirits, and cloths; and the exports, grain, wool, hides, tobacco, iron and copper ore, and coral.

ALGOA BAY, an indentation of the S. E. coast of Africa, in Cape Colony, about 425 m. E. of the Cape of Good Hope. It has excellent anchorage, and receives the Sunday river. Near Cape Recife, the W. point, is Port Elizabeth, the port of Uitenhage, 18 m. inland.

ALGOMA, a judicial district of the province of Ontario, Canada, forming the extreme N. W.

part of the province, bordering on Lakes Superior and Huron, and extending E. as far as the most westerly branch of the French river; pop. in 1871, 4,807. The W. and N. boundaries are undetermined, but the area is probably not less than 40,000 sq. m. The district is divided into East, West, and Centre. In the first are Killarney, Spanish River, and Mississauga; in the second, Bruce Mines and Sault Ste. Marie; in the third, Batchewaning, Michipocoter, Pic St. Ignace, Nipigon, and Kaminstiqua. The chief productions are timber and minerals; but though its pine forests have been worked for 20 years, the mines, rich in copper, silver, iron, and tin, were, with a few exceptions, neglected till 1871, when a large number of Americans engaged in silver mining, and by the end of that year about 20 mines had been opened, generally with great promise of success. The Lake Superior part of the district is probably one of the richest mineral regions anywhere known. In 1847 numerous companies were formed to work the mines, but most of them failed, and some years ago the government cancelled many of the grants and resumed the land. This district is approached by steamboats, which ply regularly in summer. Capital, Sault Ste. Marie.

ALGONQUINS, a family of Indian tribes in North America, which at the commencement of the 17th century covered a vast region, bounded on the north and northeast by the Esquimaux, on the northwest by the Athabaskan tribes, on the west by the Dakotas, and on the south by the Catawbas, Cherokees, Mobilian tribes, and Natchez, and extending from about lat. 37° to 53° N., and from lon. 25° E. to 15° W. of Washington. All the tribes of the family were nomadic, cultivating very little ground, and moving about in their own districts as hunting and fishing required. They resemble each other strongly in manners and customs, and the differences of dialect are easily traced to a common source. Within the same limits also dwelt the Winnebagoes, a Dakota tribe, in the west, and a large family of tribes extending from Lake Huron through the present states of New York and Ohio to North Carolina, and comprising the Wyandots or Hurons, Tionontatez, Neutres, Iroquois, Andastes or Susquehannas, Nottoways, Tuscaroras, and some smaller tribes, all of the same origin and language, but differing essentially from the Algonquins. The chief Algonquin tribes were the Crees, from Hudson Bay to Lake Superior; Nasquapees, on the Saguenay; Montagnais, on the St. Lawrence; Algonquins proper, on the Ottawa; Nipissings and Ottawas, on Manitouline; Chippewas, Menomonees, and Pottawatamies, on Lake Michigan; Miamis, Sacs, Foxes, Kickapoos, and Illinois, in the west; and on the Atlantic the Micmaes, Etechemins, Abenakis, Sokokes, Massachusetts tribes, Pequods, Narragansetts, Mohegans, Lenni Lenape or Delawares, Nanticokes, the Powhatan tribes in Virginia, Pampticoes in North Carolina, and Shawnees in the south. West of the Mississippi were

the Blackfeet and Cheyennes, regarded as isolated branches of the same family. Various dialects of the Algonquin have been studied and reduced to grammatical rules, by missionaries and others, Eliot's Indian Bible being the most extensive work published in it, while the labors of Eliot, Edwards, Roger Williams, House, Schoolcraft, Zeisberger, Du Ponceau, Gravier, R  le, Le Boulanger, Baraga, and Cuq furnish the best data for study and comparison. At the beginning of the 17th century the Algonquins numbered apparently more than a quarter of a million; and the survivors must even now number 40,000.—There is no little confusion in the later writers as to the locality of the Algonquin tribe, from which the family took its name; but from the earlier explorers it is evident that they lived on the Ottawa river, the chief band being called also Kichispirini (men of the great river). They were enemies of the Iroquois, and levied a sort of toll on all the canoes that passed down the river to trade with Europeans. They induced the French to join in the war against the Iroquois, but were almost annihilated by war and disease. The only remnant of the Algonquins is at the Lake of the Two Mountains. Their

dialect has been modified by intermixture with the kindred Nipissings and Ojibways, so that its original dialectic forms are scarcely traceable.

ALGAZIL, or **Alguacil**, in Spain, an inferior officer of the law, answering to a constable or bailiff. The alguazils are appointed by the judges, the *alguazil mayor* or head constable by the town council.

ALHAMA, the name of several towns in Spain, from the Arabic *al* and *hammiyat*, a warm bath. The most important is about 25 m. S. W. of Granada, picturesquely situated in the Sierra de Tejada; pop. about 7,500. Its mineral waters were in much request among the Moors, who drew a large revenue from the springs. The water is sulphurous, strongly impregnated with nitrogen gas, and on the surface a substance like oil may be observed; while in cold weather a sort of soapy substance is deposited on the pipes through which the water passes. In Roman times the site was occupied by Artigi (or Astigi) Juliensis, one of the chief inland cities of B  tica. It was afterward a Moorish stronghold, in which the treasury of the kings of Granada was guarded. It was captured by the Spaniards by a night assault in February, 1482.

The Alhambra, from the Albayc  n.

ALHAMBRA (Ar. *Kal-al-hamrah*, the red castle), a suburb of Granada, fortified in the strongest manner known to the middle ages, capable of containing 40,000 men, and enclosing the exquisite remains of a Moorish palace, whose beauties have been celebrated by all travellers, and admirably illustrated by the pen of Washington Irving. Situated in the midst of noble woods, surrounded by gardens, and built with sumptuousness and yet with taste, this beautiful spot contained everything that could contribute to the security and gratifica-

tion of the Granadian princes. The Hall of Lions is the grand apartment of the palace; it is so called from a splendid fountain supported by lions, and is entirely constructed of marble and alabaster, and ornamented with the most delicate fretwork and arabesques. The Hall of the Abencerrages is still more beautiful. The ceiling is of cedar wood, inlaid with mother-of-pearl, ivory, and silver; and the walls are stuccoed and ornamented with arabesques of the most elegant and intricate design. The colors still retain their brilliancy,

and the delicate filigree and tracery are in perfect order, after a lapse of 500 years. The principal building was begun by Ibn al-Ahmar in 1248, and finished by his grandson Mohammed III. about 1314, but the principal decorator was Yusuf I. Since the Castilian conquest of Granada it has undergone a series of disfigurements almost without interruption. Charles V. modernized some of its most characteristic portions in order to fit it for his own residence. Successive governors afterward pillaged it. The French blew up eight of the towers and tried to demolish the whole; and it is only within ten years that the remains have received intelligent care. The palace is now under the charge of a governor and a number of invalid soldiers. The Alhambra style is reproduced in a particular court in the crystal palace at Sydenham; and Owen Jones has published a work richly illustrated on the ornamentation and architecture of the Alhambra.

ALHONDEGA, a fortified granary in the suburbs of Guanajuato, Mexico, which gives its name to the first battle between the insurgents and the troops of the mother country in 1810. After the priest Hidalgo had taken up arms, he first endeavored to attack Guanajuato, against which he marched Sept. 28. Riañon, the commander, did not attempt to defend the city, but shut himself up with the Spanish troops and old Spaniards in the Alhondega. The Spaniards were well armed, and the troops of Hidalgo, except two creole regiments, were equipped with slings, bows, pikes, *machetes* or cane knives, and clubs. The Indians assaulted the place with great gallantry, charging up to the Spanish artillery, which they sought to muzzle with their hats and blankets. On the other hand, the Spanish fire did fearful execution, until at last, the guns being without balls, shells were improvised by filling with powder the iron flasks in which quicksilver was brought

from Spain, and firing them among the assailants. It has also been said that bags of dollars were used instead of grape-shot by the desperate defenders. At last Riañon was killed, the works were carried by storm, and the whole garrison was massacred. The number of victims is estimated at 2,000, one family alone having lost 17 members. The battle terminated on Friday night, and on Saturday morning not a Spaniard was alive in the city, and the very houses they had occupied were destroyed.

ALI, pasha of Janina, born at Tepeleni, Albania, about 1741, executed in February, 1822. His family had for generations held the town and territory of Tepeleni as a fief from the pasha of Berat. His father, having been driven from his home by his own brothers, afterward besieged them at the head of a troop of klephts and burned them alive. His mother, of the wealthy Kameco family, was noted for her ferocious character. At her instigation the young Ali affiliated with brigands, and having regained his father's estates, made marauding incursions into neighboring territories. His subsequent alliance with the pasha of Janina, and the extent of his depredations, subjected him for some time to the displeasure of the Porte; but after the execution of his father-in-law, the pasha of Delvino, and the marriage of the latter's successor with Ali's sister, he acquired supporters at the divan, and procured the appointment of sub-inspector of highways, in which post he compounded with robbers for a share of the booty. His superior was beheaded, while Ali saved himself by timely presents at Constantinople. During the war of 1787 and the succeeding years, between the Porte and Russia and Austria, Ali Pasha, though keeping up a treasonable correspondence with the Russians, rendered good service to Turkey. He obtained the appointment of inspector of public highways, with peremptory orders to suppress brigandage. Levying a strong force, he soon

Interior of the Alhambra—Hall of the Abencerrages.

carried out his instructions, and having cleared the roads and made war on his former ally, the pasha of Janina, he concocted a forged order from the Porte under which he occupied that pashalic, the subordinate beys of which were in a state of open revolt. His public services, and still more his bribery, procured him the appointment to the pashalic in 1788, and by force or fraud he extended his dominion over the greater part of northern Greece. He seized the Venetian territories on the coast of Albania so soon as the French army occupied the Italian possessions of the republic in 1797, and opened a negotiation with Napoleon for his support in case the French expedition against Turkey should succeed. Napoleon sent M. de Poiquerville to Janina; but on the defeat of the French in Egypt Ali Pasha sided with the Turks and the English, and assisted in driving out the French from Prevesa and Parga (1802). He carried on a war of extermination against the Suliotcs, an independent Christian mountainee population of Epirus, and subdued them (1803) after three years' heroic resistance on their part. He still continued to keep up a show of allegiance to the Porte, by which he was appointed governor general of Roumelia. His schemes of aggrandizement were notorious, but he bribed Turkish officials, and never openly set the power of the Porte at defiance. This cautious policy was at last forgotten. Ismail Pasha, a former confidant of Ali, held an appointment at Constantinople. Ali, either from revenge or fear of disclosures, hired assassins to kill him. The attempt having failed, the assassins made a full confession. Ali was now outlawed. An army marched against him, which he at first repulsed (1821), but at last, besieged by Kurshid Pasha in Janina, and deserted by his Ottoman adherents, he retired to a stronghold on the lake, in which he kept his treasures and his magazine, threatening to blow himself up unless he received an amnesty. The cupidity of the Turks being aroused by his treasure, it became important to secure the place. The incidents of the closing scene are variously narrated; but the general facts are that he was deluded by a pretended firman of pardon into a personal interview with Kurshid Pasha, in which he was attended by a small body of his officers. In this interview the sultan's commands for his decapitation were made known, on which Ali Pasha immediately fired at his enemies, and killed or wounded some, but was himself shot dead. His head was cut off and sent to Constantinople. Only about 20,000,000 francs of his money were found by the Turks. His daughters were sold as slaves; his sons were all put to death; his daughter-in-law was dishonored and drowned. As he contributed to the prosperity of the territories under his rule, he was regarded as rather an enlightened ruler by many Englishmen, including Lord Byron, who visited him at Janina.

ALI (Ali ben Abu Taleb), a Mohammedan caliph, reigned 655-661. He was adopted and brought

up by Mohammed, his blood relation, married the prophet's daughter Fatima, and is believed to have been his first disciple. On the death of Mohammed without male issue, he had claims as next of kin to the succession; but he deferred to those of Abubekr, Omar, and Othman, who were successively elected by the Moslems, and were supported by Ayesha, the prophet's widow, an inveterate enemy of Ali. It was not till after the assassination of Othman that he assumed the sovereign power. The question of his right to the succession divides the Mohammedan world into the two great sects of Sunnis and Shi'ahs, the former denying Ali's right, the latter affirming it. Ali's first act of power was the suppression of a rebellion fomented by other pretenders to the crown, who were abetted by Ayesha. The rebels Zoba'ir and Talha were defeated and slain, and Ayesha was taken prisoner. A new opponent soon arose in Moawiyah, who succeeded in establishing himself in Damascus, and even carried the war into Ali's own territories and seized the two holy cities. Three fanatics, having determined on ridding the world of both pretenders, succeeded in killing Ali, but failed in their attempt on the life of Moawiyah. Ali left three sons, one of whom, Hassan, succeeded him for a short time.

ALIBAUD, Louis, a Frenchman notorious for his attempt to murder Louis Philippe, born at Nîmes in 1810, died on the scaffold, July 11, 1836. In his 18th year he entered the army as a volunteer. During the revolution of 1830 he went over to the popular side, and was wounded at the barricades. Invalided in 1834, he resided alternately at Perpignan, Barcelona, and Paris. His attempt to shoot the king, inspired by political fanaticism and a morbid satiety of life, was made June 25, 1836, as his majesty was leaving the Tuileries in his carriage. Being instantly seized by the soldiery, his only regret was that he had failed in his endeavor.

ALIBERT, Jean Louis, a French physician, known for his study of cutaneous diseases, born in Villefranche, May 26, 1776, died in Paris, Nov. 6, 1837. His inaugural thesis, on "Pernicious Intermittent Fevers," passed through five editions and had an unusual success for a treatise of that nature. About 1803 he was appointed physician to the hospital St. Louis in Paris, and immediately began the investigation of diseases of the skin, publishing in 1806 the first numbers of his great work on cutaneous diseases. In 1821 he was appointed to the chair of therapeutics in the faculty of medicine. He wrote on a variety of medical subjects, and was remarkable for an elegant style. He was one of the founders of the *société médicale d'émulation*, and several of the addresses which he pronounced before this society did much to establish his literary reputation. • He was physician in ordinary to Louis XVIII., by whom he was created a baron and officer of the legion of honor. He was also physician to Charles X. His principal works are: *Traité des fièvres per-*

nieuses intermittentes (1804); *Description des maladies de la peau observées à l'hôpital St. Louis* (large folio, with 51 plates, 1806-'26); *Précis théorique et pratique sur les maladies de la peau* (1810-'18); *Physiologie des passions, ou nouvelle doctrine des sentiments moraux* (1825); *Monographie des dermatosés* (1832); *Clinique de l'hôpital St. Louis* (1833).

ALI BEY, a Caneasian slave, who, by the favor of his master, Ibrahim Bey, rose to wealth and importance in Egypt, and became one of the Mameluke beys, born in 1728, died in 1773. He became chief of the Mamelukes in 1763, and, having secured himself adherents in Cairo, he slaughtered the other beys in 1766, and assumed the government, proclaiming himself sultan in 1768. The Porte, then occupied with war against Russia, left him uncontrolled. His idea, derived from intercourse with Europeans, was the restoration of the Egyptian kingdom. He formed an alliance with Daher, pasha of Acre, and they seized on Mecca, and sent a fleet into the Red sea. In 1770 they overran Syria, and Daher and Mohammed, Ali's general and adopted son, having routed the Turkish army, were on the point of rendering themselves masters of the country, when Mohammed, either alarmed for himself or gained over by the Turks, precipitately quitted the army, and, returning to Egypt, engaged in a war against Ali, who fled. The latter, however, renewed the contest jointly with Daher, and for a time with great success, but was finally captured in battle and slain.

ALICANTE. I. A S. E. maritime province of Spain, forming a part of the former kingdom of Valencia; area, 2,096 sq. m.; pop. in 1867 (estimated), 426,656. One half of the province consists of a bare chain of high mountains, with partly sterile steppes, without trees or water; but the southern portion is generally level and fertile, with a mild climate, and agriculture flourishes. Among the products are

mineral salt, sea salt, and esparto, besides silk, grain, and fruits of all kinds. The chief river is the Segura. The principal towns, besides the capital, are Alcoy, Denia, Villajoyosa, Jijona, Monovar, Elche, and Orihuela. II. The capital of the province, and the principal port of Valencia, on a bay of the Mediterranean, 230 m. S. E. of Madrid; pop. about 32,000. It is situated partly on the slope of a hill 400 feet high, on the top of which is a strong castle, and partly on the shore of the bay. The latter portion is modern and elegant. From the northern slope of the mountain is produced the celebrated Alocue wine. The commerce of Alicante was formerly extensive, but has decreased during the last 20 years. The chief exports are raisins, almonds, olive oil, saffron, and vanilla. The city has a cathedral, a government tobacco factory employing about 4,500 girls, and a bull ring capable of seating 11,000 persons.

ALICATA. See LICATA.

ALIEN, a person who was born out of the jurisdiction and allegiance of a country, and who is not a citizen of that country. Not all foreign-born persons are aliens by our law, because they may be within certain excepted classes, as the children of the nation's ambassadors born in other countries, or of American citizens temporarily sojourning abroad; or they may have become citizens by naturalization. In the United States citizenship and alienage are determined by the laws of the federal government. The subject of naturalization under these laws is treated elsewhere. (See NATURALIZATION.)—Attica, the foremost state of ancient Greece, treated foreigners with much liberality. While Sparta was jealous of strangers and excluded them, at Athens foreigners were freely admitted, and at one time constituted half her residents. They were subjected to taxes and to some other light burdens and disabilities which were not imposed on native citizens;

but on the whole the policy observed toward them was humane and generous, and sometimes they were received into citizenship. In other states of Greece individuals and sometimes whole classes of aliens were endowed with civil rights, such as the privilege of intermarriage, of holding real property, and of exemption from special taxation. In Rome, under the emperors, foreigners could acquire and dispose of property, could devise and inherit it, and sue in the courts; and they enjoyed other rights accorded by the *jus gentium*, that is to say, the mere natural rights of persons, though

Alicante.

they were deemed the especial and distinctive privilege of Roman citizens. In Germany and France, in the later periods, foreigners were not only denied civil rights, but were forced to invoke the protection of the native barons or seigneurs, who imposed the heaviest exactions as the price of their protection. In France, in some districts, the alien was forbidden, after a certain term of residence, to leave the lord's domain; and if he died within it, leaving no heirs there, the lord claimed the right of succession to his property. This prerogative of the seigneurs, later assumed by the sovereign himself, was what in modern times was known as the *droit d'aubaine*. It has existed down to a very recent period in Europe, at least in the milder form of the *droit de détraction*, and practically exists now, or did only a few years ago, as Mr. Attorney General Cushing suggested, in many of our own states; and it is the subject of clauses in some of our latest treaties with European powers. This *droit d'aubaine*, as it was asserted by the king of France, consisted sometimes in a right to levy a tax on strangers on certain occasions, and sometimes in the claim of inheriting to strangers who left no heirs within the kingdom. It was abolished in France in 1790, restored by the *Code Napoléon* on the plea of reciprocity, and abolished finally in 1819, when the right of succession was conceded to foreigners to the same extent as it was enjoyed by native-born Frenchmen. The French legislation has had the effect to break down this exaction in other European states; but Great Britain and the United States have not been so liberal. A very recent treaty with Prussia, which will illustrate the present international practice on this point, contained provisions intended to relieve the subjects of Prussia from their disabilities in respect to real and personal property here, and declared that on the death of such an alien in possession of property, his heirs should have reasonable time to sell it and withdraw the proceeds, "except from all droits of detraction on the part of the government of the United States." Soon after the conclusion of this treaty, the Prussian minister complained that his countrymen did not enjoy in all our states the benefit of the treaty stipulation, and the question arose whether the federal government could make a treaty whose provisions of this character could bind the states; for though the federal government has supreme and exclusive cognizance of questions of citizenship and alienage merely, yet each state is at liberty to make its own laws in relation to the enjoyment and devolution of property within its own limits. The opinion of the attorney general was very clear and explicit to the effect that the treaty-making power of the general government must bind the states as to the provisions in question. But, so far as appears, no decision on the subject has ever been made by the courts.—As to real property, subject to the right of forfeiture in the state or sovereign, aliens under the common law

may take by act of the party, as the phrase is, though they may not take by act of the law. In other words, an alien may take real estate by purchase, or even by devise, these being acts of parties; but he cannot take by inheritance, for that is a mere operation of the law. When the alien takes, as in the two former cases, the estate vests in him, and he may hold it against every one but the state; nor can the state enforce its right of forfeiture without proceedings for that purpose, or, in legal phraseology, without an inquest of office found. Until this is done, the alien may exercise complete legal domain over the property, just as a citizen may do. But though he may sell it, his grantee takes no better title than the alien had, and he is therefore as liable to forfeit the lands as the alien was. At common law, as just implied, the alien has no inheritable blood, that is to say, he can neither take nor transmit real property by descent. Thus it was formerly held that a grandson could not inherit to his grandfather, though both were native-born subjects, if the intervening son, the grandson's father, were an alien. But a statute was passed in the reign of William III. which cured this disability, by providing that native-born citizens might inherit to their ancestors, notwithstanding the alienage of any intervening ancestor. This statute was reenacted in 1830 in New York, and in many other states before that time.—The disabilities of aliens in respect to real property have been materially lessened in most of our states; and in some they are entirely removed, as in Massachusetts, Maryland, Florida, Ohio, Illinois, Iowa, Wisconsin, Nebraska, Dakota, and Nevada. In New York, South Carolina, Texas, and many others, the alien may take, hold, and devise lands after declaring his intention to become a citizen in conformity with the naturalization laws. In Connecticut and California the alien, if a resident in the state, may purchase, hold, inherit, and transmit lands in the same manner as a citizen. The right of forfeiture, it should be observed, is very rarely exercised by the states; on the contrary, the legislatures are very liberal in making laws to cure defects of titles arising out of the alienage of former holders, and in releasing in favor of the natural heirs the right of escheat which may have accrued to the state by the death of an alien ancestor in possession of lands.—In respect to personal property, aliens may at common law take, hold, and dispose of it, and make and enforce contracts in respect to it, just as native citizens may do. An alien in New York may take a purchase-money mortgage on land sold by him, and on a foreclosure may buy and hold the land. But it is doubtful whether he could make such a purchase on foreclosure of his mortgage on lands in which he never had any other title than the mortgage. The revisers in 1830 proposed a section to confer the power, but it was not adopted.—An alien enemy, that is to say, the subject of a state actually at war with us,

cannot maintain an action in our courts, unless he is here by license of our government or is otherwise under its protection. But an alien friend, whether resident here or not, may sustain in our courts an action like our own citizens for any injury to his person or rights. As to non-resident aliens, an illustration of the rule is furnished by the suits for infringement of trade marks in this country, which have been in several instances maintained by English manufacturers. Suits by or against aliens, whether living here or abroad, to which a citizen of the United States is an opposite party, may be brought under the laws of the federal government in the United States circuit courts; and suits by aliens for torts in violation of the law of nations may be brought in the district courts. Upon the outbreak of a war with the alien's country his civil capacity to sue is suspended, and his property is subject to confiscation. A statute of the United States of 1798, still in force, provides that in such an event the subjects of the hostile nation within our territory may be restrained, secured, or removed as alien enemies, though they shall be allowed such time for removal of their effects as is provided by treaties with their countries. Aliens are incapable of serving on juries, voting, or holding office. Where they can hold property, they are generally subject to militia duty and the other burdens and taxes of citizens. The practice of trying aliens by a jury *de medietate lingue* (half aliens) has fallen into general disuse. The power to expel aliens from the state is vested in France in the minister of the interior, and in England and America theoretically in the executive, though it has never been exercised in either of the two latter countries except in pursuance of an act of parliament or of congress. Such an act was passed in England in 1848, but a report made in 1850 showed that it had not been enforced in a single instance.—In England some important points of the law respecting aliens have been lately settled by the enactment of the naturalization act of 1870. It declares that henceforth real and personal property of every description may be taken, acquired, held, and disposed of by an alien, in the same manner in all respects as by a native-born British subject; and that a title to real and personal property of every description may be derived from, through, or in succession to an alien, as it may be from a native citizen of the kingdom. The act also provides that any alien naturalized in Great Britain may make a declaration of alienage after proclamation of any treaty with his native state which insures that privilege for its subjects; and also that any person born out of her majesty's dominions of a British father may, if of full age and under no disability, make a declaration of alienage. From the passage of the act no alien shall be entitled to be tried by a jury *de medietate lingue*, but shall be triable like a native British subject. Provisos of the act declare that its terms shall not qualify an alien for any

office or for any municipal, parliamentary, or other franchise, nor enable him to enjoy any rights or privileges as a British subject, except the rights and privileges as to property conceded by the act. Other significant but less important provisions are contained in the statute.

ALIGHIERI, Dante degli. See DANTE.

ALIGHUR, or Allygurh. I. A district of British India, in the Meerut division of the North-western Provinces, between lat. $27^{\circ} 27'$ and $28^{\circ} 11' N.$, and lon. $77^{\circ} 32'$ and $78^{\circ} 47' E.$; area, 2,149 sq. m.; pop. about 1,200,000. With the exception of a ridge near the middle of the district, the surface is almost level. The crops are wheat, barley, millet, pulse, indigo, cotton, tobacco, and sugar. At the beginning of this century Alighur was the seat of power of the French adventurer Perron. II. A fort in the preceding district, 55 m. N. of Agra, on the road to Meerut. It was held by Perron with a force of Mahrattas in 1803, and was stormed by the British, Sept. 4, about 2,000 of the garrison falling in the assault. A regiment of sepoy's mutinied here in May, 1857, and held the place till October, the English escaping without loss of life.

ALIMENT, or Food, all the solid and liquid substances requisite for the nourishment of the body. The living body is in a constant state of change. Every one of its motions, every exertion of the voluntary muscles, even the contractions of the heart and the movements of respiration, are attended by the disintegration of some portion of the tissues, which must be renovated in order to maintain their vital activity. This constant waste of tissues demands a corresponding supply of food, by which the loss may be made good. Properly speaking, all the ingredients of the body constantly require to be replaced, and must therefore form a part of the food. Alimentary materials are accordingly divided into groups, distinguished from each other by certain characteristics. 1. The first comprises the inorganic substances proper, namely, water and the mineral salts. They are all essential as ingredients of the food, since they form an essential part of the bodily frame. Of these inorganic substances, water is the most abundant and the most constantly indispensable. It forms from two thirds to three quarters of the entire mass of the human body, and is constantly discharged from the body by the perspiration, the respiration, and the urine. The water thus lost must consequently be replaced by that which is taken with the food and drink. The quantity of water taken in to supply the wants of the system is for an adult man, on the average, about $4\frac{1}{2}$ pounds per day. Of the mineral salts which are necessary constituents of the body and of the food, chloride of sodium, or common salt, and phosphate of lime are the most important. They exist in greater or less abundance in every one of the solids and fluids of the body. Chloride of sodium, for example, is present in the blood in the proportion of $\frac{1}{4}$

parts per thousand; and phosphate of lime exists in the bones and other solid tissues in much greater proportion. Both these substances are also ingredients of the food. Chloride of sodium is found in muscular flesh, or lean meat, in the proportion of two parts per thousand, and we are also in the habit of adding it to the food as a condiment. Breeders of sheep, cattle, and horses always find that a liberal supply of common salt improves greatly the condition of the animals. Phosphate of lime exists in the muscular flesh of animals, in fish, oysters, eggs, in the cereal grains, in peas, beans, potatoes, beets, turnips, &c., and even in most of the juicy fruits. The alkaline salts, the carbonates of soda and potassa, are also necessary to the nourishment of the body; since the blood and most of the secretions must have an alkaline reaction, and this reaction is for the most part communicated to them by the presence of the carbonates of soda and potassa. Unlike the mineral salts, however, the alkaline carbonates are not usually introduced into the body under their own form. Many of the summer fruits and vegetables contain salts of soda and potassa combined with various organic acids, such as the malates, tartrates, and citrates of these bases. These salts are decomposed in the interior of the body, and their vegetable acids replaced by the carbonic acid. Thus they become alkaline salts, and provide for the proper constitution of the animal fluids. 2. Another group of the alimentary substances comprises starch and sugar. These two resemble each other in their chemical constitution, being composed of carbon, hydrogen, and oxygen alone. They are further connected by the fact that starch may by various means be converted into sugar. The readiest mode of doing this is perhaps by boiling with a dilute acid. If 320 grains of starch be boiled for five hours with about two fluid drachms of sulphuric acid in a pint of water, it will be found to have lost the properties of starch and acquired the sweet taste and other characteristic qualities of sugar. There are various other modes by which the same change may be accomplished; and in fact in very many instances, if not in all, in which sugar is formed in the juices of vegetables, it has first appeared in the form of starch. Of the substances belonging to this group, the different varieties of starch are the most abundant. Starch is found, in the form of minute rounded grains, in a vast number of vegetable productions. It is abundant in wheat flour, in rice, Indian corn, rye, barley, oats, potatoes, peas, and beans, and enters in smaller proportion into nearly every article of vegetable food. In the process of cooking, or heating the starch in contact with water, its grains swell up, become softened, absorb water, and at last, if the heat be sufficiently long continued and the water sufficiently abundant, they fuse together into a gelatinous, homogeneous mass. In this condition they are much more digestible than in the raw state,

and it is in this form that starch is almost always actually used as food. Sugar is also taken not only in its purified form, as an addition to other substances, but also as a natural ingredient in the sweet juices of nearly all the fruits and most vegetables. Wheat flour contains 5 per cent. of sugar, milk nearly 5 per cent., beets 9 per cent., pears over 10 per cent., and peaches and cherries from 16 to 18 per cent. Vegetable substances containing starch and sugar are always useful, and in the long run indispensable for maintaining health in the human species. A diet exclusively composed of meat and other animal substances becomes after a short time exceedingly distasteful, and an almost irresistible desire is experienced for food of a vegetable origin. This is an instinctive demand of the system. Even dried or preserved vegetables will not answer the purpose indefinitely, for there is something in the fresh vegetable juices which is essential to health; and if fresh vegetables are excluded from the food for a long time, all the symptoms of scurvy begin to manifest themselves, showing a generally disordered condition of the nutritive functions. 3. A third group of alimentary materials comprises the fats. These substances, like starch and sugar, consist of carbon, hydrogen, and oxygen as their chemical elements, but the proportions in which the elements are combined are not analogous to those in the former group; and the fats have other distinctive characteristics also. They are both of animal and vegetable origin. They constitute the greater part of the adipose tissue or fat of animals, more than 25 per cent. of the yolk of eggs, the whole of the butter derived from cow's milk, 9 per cent. of Indian corn, 32 per cent. of olives, and in walnuts and filberts as much as 50 or even 60 per cent. Fat, in some one or more of these forms, is extremely useful and perhaps indispensable as an article of food. The fact that it constitutes over $3\frac{1}{2}$ per cent. of human milk, which is the first and exclusive food of the infant, shows this to be the case, at least for that age; and the general desire which is felt by the healthy appetite for a certain proportion of fat is a sufficient indication of its importance. 4. The last group of alimentary materials comprises albuminoid substances. (See ALBUMEN.) They are distinguished from both the starchy and fatty substances by the fact that they all contain nitrogen; and they are sometimes designated as the nitrogenous elements, in distinction from the others, which are non-nitrogenous. The albumen of the white of egg is one of the most important and familiar. A substance very similar in composition to albumen, namely, musculine, forms the principal mass of muscular flesh, and is the chief ingredient in lean meat used for food. Caseine is present in milk, and in a coagulated form constitutes the principal part of cheese. Legumine is found in peas and beans, and gluten is the albuminoid ingredient of wheat flour. Altogether, an adult man usually

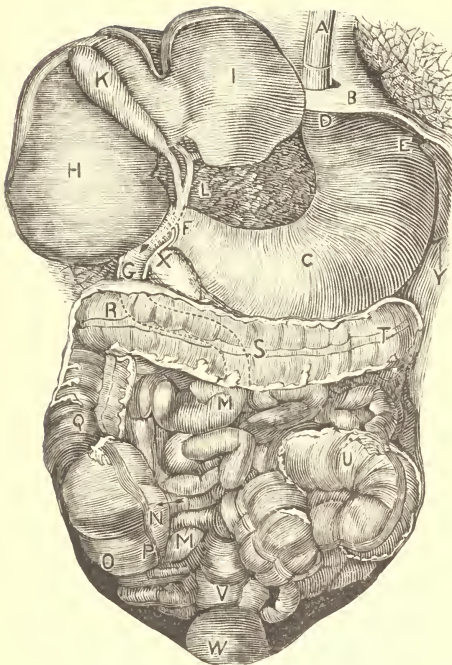

consumes rather more than a quarter of a pound of albuminoid matters (calculated in the dry state) during 24 hours.—No one of the groups of alimentary materials enumerated above, taken singly, is sufficient for the continued nourishment of the body. This is sufficiently evident for the inorganic substances, such as water and the mineral salts. Vegetables have the power of assimilating these matters, and converting them into the ingredients of the vegetable fabric; but animals require for their nourishment materials which are already animal or vegetable in their nature. But even these substances, combined with starch, sugar, or oil, are also insufficient. Dumas and Milne-Edwards found that bees fed upon pure sugar and water soon ceased to work, and afterward perished. They thrive only when supplied with waxy and other vegetable substances in addition. Magendie found that dogs fed upon starch and sugar, or upon an exclusive diet of fat, became after a time debilitated, and died with symptoms of great disturbance of the nutritive functions. Boussingault fed a duck upon butter alone; but, although the quantity of this alimentary substance was abundant, namely, from 1,350 to 1,560 grains per day, the animal at the end of three weeks died of inanition. All the tissues of the body were infiltrated with oleaginous material, but this substance had proved incapable of supporting life. Lehmann put himself upon a regimen consisting solely of non-nitrogenous substances, such as starch, sugar, gum, and oil, but was only able to continue this course for two or at most for three days at a time, owing to the disturbance of the general health produced by it. The unfavorable symptoms, however, rapidly disappeared on his resuming an ordinary mixed diet. The substances just mentioned being deficient in so important an element as nitrogen, this was at one time regarded as a sufficient explanation of their inability to sustain life; and the albuminoid or nitrogenous materials were therefore supposed to be the only absolute and completely nutritious ingredients of the food. Direct experiment, however, showed that these substances themselves, when taken alone, were also insufficient. Magendie fed dogs upon pure gelatine and pure fibrine, and found at the end of some days that the animals lost their relish for the food, became emaciated, and died with symptoms of inanition. To be completely nutritious, therefore, the food must contain not one but all of the groups of alimentary substances, and these substances must be present in their true proportion. This shows the futility of the attempts which have sometimes been made to fix the nutritive value of different kinds of food by ascertaining their ultimate chemical composition, and particularly by the amount of nitrogen which they contain. The nutritious qualities of an article of food depend upon the proportion of its different ingredients, not only as taken alone, but also as used in combination with other substances.

Its digestibility and the extent to which it conforms to the appetite and natural taste are also important elements in the question. The nutritive value of an article can therefore only be determined by direct experiment and observation; that is, by employing it as food, alone and in combination. Thus all those substances which are found by universal experience to be the most useful are distinguished by a variety of composition. Milk, which for the young infant is during a certain period the only food employed, contains water, mineral salts, caseine or an albuminoid ingredient, butter or fat, and a peculiar variety of sugar. Eggs contain albumen, water, fat, and salts. Wheat flour, as well as the bread which is made of it, contains gluten, water, salts, starch, and a small quantity of sugar. In practice, at least for adults, a judicious variety in the diet is found to be indispensable for the maintenance of health.—Of all articles of food, bread is perhaps the most important. The best and most nutritious bread is that made from wheat flour. The flour contains, in 100 parts, on the average, 72 parts of starch, $7\frac{3}{10}$ parts of gluten, $5\frac{1}{10}$ parts of sugar, and 12 parts of water, together with gum, phosphates of lime and magnesia, alkaline sulphates, and a little chloride of sodium. It is first kneaded into a paste with about one half its weight of water, a little yeast added and thoroughly mingled with the mass by continued kneading, and the dough then allowed to remain for some hours at a moderately warm temperature. During this time the yeast excites in the sugar of the flour a fermentation, by which it is converted, as in ordinary fermentation, into alcohol and carbonic acid. The alcohol penetrates the dough and escapes by evaporation. The carbonic acid, however, is developed throughout the dough in the form of minute gaseous bubbles, which are confined and entangled by the tenacious gluten of the flour; and the whole mass thus becomes inflated or puffed up by the gaseous expansion. This is the rising or fermentation of the dough. It is then transferred to an oven and kept there at a temperature of about 380° F. until the baking is complete. The effect of baking at this high temperature is as follows: First, the starch upon the outside of the loaf is converted into dextrine and hardened into a brownish, brittle layer, which is the crust; secondly, the gluten throughout is also solidified and at the same time acquires an agreeable and wholesome flavor; thirdly, the starch grains become swollen, fused, and hydrated, fixing permanently in their substance a certain proportion of the water with which the flour was mingled. Thus, after baking, the bread always weighs more than the flour of which it was made, owing to the necessary combination of water with the starch in the baking process. Usually one pound of flour is found to produce in this way one pound and a quarter of bread. When removed from the oven and cut open, the interior of the loaf is seen to present a spongy

appearance, owing to a multitude of little cavities distributed through its substance. These are the cavities originally produced by the bubbles of carbonic acid developed in fermentation, and which retain their figure in consequence of the stiffening and coagulation of the gluten by the baking process. This is one of the main objects of fermentation; for the spongy texture which the bread thus receives enables it to be more easily masticated and mingled with the saliva and gastric fluids, and thus renders it more healthy and digestible.—Cheese is made by coagulating the caseine of milk with rennet, after which the coagulum is compressed, in order to free it from the watery, oleaginous, and saline ingredients of the milk; and when reduced to a sufficiently solid condition, it may be kept for an indefinite time. In many kinds of cheese, however, more or less of the oily ingredients of the milk are retained entangled with the caseine, by which it acquires a richer and stronger flavor. Butter, on the other hand, is simply the oleaginous portion of the milk, separated from the remaining constituents. In the natural condition of the milk the butter is in the form of microscopic globules, or spherical masses, of a semi-solid consistency, suspended in a state of minute subdivision in the serous liquid. By the operation of churning, these little globules are made to cohere mechanically together, and gradually the whole of the oleaginous substance is separated in a distinct pasty mass. It is still further freed from the accompanying ingredients of the milk by pressure and kneading under water, and is finally obtained as butter in a nearly pure condition.—The effect of cooking upon food is twofold. In the first place, it softens and disintegrates the substances which are naturally too hard for digestion, and thus renders them amenable to the digestive operations. This is the effect produced upon many vegetable substances, such as starch grains wherever they may be found, and all substances having a resisting envelope or a tough and solid texture, such as peas, beans, potatoes, turnips, and the like. In animal substances, on the other hand, the most useful effect of cooking appears to be the partial transformation of the albuminoid matters, as in roast meat, by which they acquire a peculiar and agreeable flavor. There is reason to believe that this flavor, besides being pleasant to the palate, is also the indication of a chemical change in the albuminoid matters, by which they are prepared for digestion and become better fitted to subserve the nutrition of the body.

ALIMENTARY CANAL, a tubular passage, existing in man and all the higher animals, composed principally of a muscular layer and a mucous membrane, extending from the mouth to the anus, and designed for the reception, transmission, and digestion of the food or aliment. The cavity of the alimentary canal is continuous, anatomically, from its commencement to its termination, forming a hollow passage

through which the food is carried in the digestive process. Its different parts are, however, partly separated from each other at various points by constrictions and muscular bands, which are alternately closed and opened, to allow of the temporary retention or onward movement of the alimentary materials. The different portions of the canal are also distinguished from each other by varieties of form and size, the development of their muscular layers, and the structure of their mucous or lining membrane. Owing to this variety of structure, and the different characters of the secretions produced, the action of the alimentary canal upon the food varies in its different parts; and the process of digestion to which the food is subjected consists of the successive or combined operation of the whole. The principal portions into which the canal is thus divided, in the human subject, are known as the mouth, the œsophagus, the stomach, the small intestine, and the large intestine.—The mouth is the cavity included between the opening of the lips in front and the fauces behind. In it are the teeth, intended for the mastication and comminution of the food; the tongue, a muscular and sensitive organ, which subserves both the sense of taste and the proper movement and admixture of the food in mastication; and a lining membrane which contains mucous glandules destined to supply a viscid secretion forming part of the saliva. There are also the parotid, submaxillary, and sublingual glands, situated in the immediate vicinity of the mouth, which pour their secretions into its cavity, and thus complete the formation and supply of saliva, which is mingled with the food in mastication and reduces it to the condition of a soft, pasty mass.—Immediately behind the fauces is the pharynx, a short funnel-shaped passage leading directly to the œsophagus. The latter is a nearly straight tube of uniform size, about nine inches long and rather less than one inch in diameter. It passes through the neck and posterior region of the chest to the upper part of the abdomen, where it terminates in the stomach. It has a double layer of transverse and longitudinal muscular fibres, by whose peristaltic or wave-like contractions the masticated food is rapidly carried from above downward. Its lining membrane is of a simple structure, and produces only a small quantity of mucus, destined by its lubricating qualities to facilitate the passage of the food. The œsophagus, in fact, is simply an organ of transmission, by which the food is transferred from the mouth to the stomach, where the more important digestive actions are to begin.—The stomach is a dilatation of the alimentary canal, lying transversely across the upper part of the intestine. Toward the left side it expands into a wide hemispherical sac or pouch; toward the right side it becomes narrowed to a smaller diameter, where it unites with the upper extremity of the abdomen. The orifice by which the stomach communicates with the œsophagus is called the *cardia* (Gr. *καρδία*,

Abdominal Portion of the Alimentary Canal.

A, œsophagus; B, diaphragm; C, stomach; D, cardiac extremity of the stomach; E, great pouch; F, pylorus; G, duodenum, H, right lobe of liver; I, left lobe of liver; K, gall bladder; L, bile duct; M, small intestine; N, entrance of small intestine into the large intestine; O, cæcum; P, appendix vermiformis; Q, ascending colon; R S T, transverse colon; U, sigmoid flexure; V, rectum; W, urinary bladder; X, pancreas; Y, spleen.

the heart), because it is situated near the heart; that by which it communicates with the intestine is called the pylorus (Gr. *πυλωρός*, a gate-keeper). Both are provided with a special circular bundle of muscular fibres by which the food, once in the stomach, is retained there for a time, to allow of the secretion and operation of the gastric juice. The gastric juice is secreted by the mucous membrane of the stomach, which is soft, glandular, and vascular in texture, and, when stimulated by the contact of the food, pours out the gastric juice in considerable abundance, as the perspiration is exuded by the skin.—Next the stomach follows the small intestine. This is a tubular canal about 25 feet in length and between one and two inches in diameter. It is thrown into numberless folds and convolutions, by which, notwithstanding its great length, it occupies a comparatively moderate space in the abdomen. It is attached to the abdominal portion of the spinal column by a thin, flexible membranous sheet termed the mesentery, which, while retaining it in its proper position, allows of the necessary movement of its different convolutions upon each other. Its muscular layers are well developed and active, and by their contractions continuously urge the semi-fluid ingredients of the food through

the tortuous windings of its internal cavity. Its mucous membrane is provided, first, with a great number of glandular follicles which secrete the intestinal juice, one of the active agents in digestion; and secondly, with minute filamentous vascular prominences or villi,

Two Villi of the Small Intestines.

A, substance of the villus; B, its epithelium, of which some cells are seen detached at B'; C D, the artery and vein, with their connecting capillary network, which envelopes and hides the lacteal radicle, E, which occupies the centre of the villus and opens into a network of lacteal vessels at its base.

which are so abundant and thickly set as to give its internal surface a velvety texture, and which by their absorbent action take up from the intestine the nutritious elements of the digested food. Into the upper part of the small intestine, a few inches below the stomach, there are also discharged two accessory secretions, namely, the bile from the liver, and the pancreatic juice from the pancreas. The small intestine terminates, in the lower part of the abdomen on the right side, by a junction at right angles with the large intestine.—The large intestine, so called from its greater capacity as indicated by a transverse measurement, is about five feet long, and from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches in diameter. It extends from its commencement in the right iliac region (see ABDOMEN) upward on the right side of the abdomen, then transversely across to the left side, then downward upon the left side, then through an S-like convolution to the top of the pelvis, and finally through the cavity of the pelvis to the anus. At the point of junction of the small with the large intestine there are two parallel folds of mucous membrane, with their edges turned toward the cavity of the large intestine, which act as a double valve (called the ileo-cæcal valve), allowing the passage of materials in this direction, but preventing their regurgitation from the large into the small intestine. The mucous membrane of the large intestine has no villi, but is provided with simple glandular follicles, which secrete various excrementitious materials. This portion of the alimentary canal contains also the refuse portions of the food, which, together with the excrementitious matters supplied by its lining membrane, assume a fecal consistency and appearance from the situation of the ileo-cæcal valve downward, and are finally discharged from the lower extremity of the large intestine.

ALIMENTUS, Lucius Cincius, a Roman historian and jurist, prætor in Sicily 209 B. C. He was

for some time a prisoner in the hands of Hannibal, who appears to have treated him with kindness, giving him an account of his march through Gaul and over the Alps. Alimetus wrote a history of Rome which is quoted by Livy. Only fragments of it are preserved. He also wrote an account of his imprisonment among the Carthaginians. He is highly praised by Niebuhr as an accurate investigator. He wrote also on law and antiquities. The fragments of Alimetus still extant are appended to Corte's edition of Sallust.

ALIMONY (Lat. *alimonium*, nourishment), in law, the allowance which a husband, by order of the court, makes to his wife for her maintenance during her separation from him. Of alimony, as of all matters pertaining to the marriage relation, the ecclesiastical courts in England had in former times exclusive cognizance. No such courts were ever established here, and the jurisdiction in respect to alimony is exercised in our states either under express statutes, or as being included in the characteristic powers of courts of chancery or equity. When the jurisdiction is assumed on the latter ground, the court grants this sort of relief in that class of cases in which the ecclesiastical courts of England would have decreed it. Ordinarily the question of alimony in the United States arises in connection with cases of divorce, partial or absolute. It has been the rule of the law until very recent legislation, especially in the United States, modified it, that all the personal property of the wife at her marriage, and all that came to her afterward, and the substantial benefit of her real estate too, vested absolutely in the husband. The law therefore put upon him the correlative duty of maintaining the wife according to his condition in life and pecuniary ability; and it is out of this duty that the wife's right to alimony in case of her lawful separation from her husband also arises. Accordingly, whenever a court adjudges or concedes that the wife may live apart from her husband for his violation of his matrimonial obligations to her, it will also decree that he make her a proper allowance for her sustenance. Observing the conditions of alimony as they were defined by the practice of the English ecclesiastical courts, some of our states, Massachusetts and Pennsylvania for example, have held that, in the absence of express statutes, they have no power to grant alimony in cases of absolute divorce; for as in the English law that kind of divorce was unknown until recently, the spiritual courts gave alimony of course only upon divorces from bed and board, or as we call them partial divorces. But in most of the states the statutes explicitly provide for alimony in all divorces. In general, and for obvious reasons, our courts will not grant permanent alimony to the wife when she is the guilty party, though, as a merciful safeguard against her further debasement, they do sometimes make such provision for her. Nor on other grounds will the courts compel the

husband to pay anything when the wife has a separate estate which is withheld by settlement or otherwise from her husband's control, and, considering his means and condition, it yields to the wife as much as she is fairly entitled to.—The provision for the wife may either be made pending a suit for divorce, whether brought by herself or by her husband, in which case it is called alimony *pendente lite* or pending suit; or it may be permanent, that is, for the term of her separation or for her lifetime, and this sort of alimony is ordered upon the passing of the decree of divorce, whether partial or absolute. As to the alimony pending suit, it is quite a matter of course to give it, whichever party brings the action; though when the husband is plaintiff, the court ordinarily requires as a condition precedent a sworn denial of her guilt on the part of the wife, or some other proof of the merits of her case. With this sort of alimony, ordinarily, the court gives a provision for the wife's legal expenses in prosecuting or defending the action. This is only just, for even if the wife is the defendant, she is not yet proved guilty, and to deny her the means of resisting her husband's suit might be to deny her the means of vindicating herself. At all events, if the wife has no means, and the husband has, he must not only support her fairly during the legal proceedings, but also supply her with means for retaining counsel and otherwise paying the legal expenses especially pertaining to the action. The allowance in these respects does not always depend on the fact whether or not the husband has an accumulated property; he may be ordered to pay it out of his daily earnings. And the principle is so reasonable that in a case where the court could not compel a husband who was plaintiff to pay alimony *pendente lite* because he had neither property nor any other resources, it ordered him to suspend his action till he could furnish his wife with the means of defending it. If the husband pay the temporary alimony ordered by the court, he is discharged of all liability for even the wife's necessities; but he is liable for them if he withholds the allowance, as he is in fact, on general principles, if no alimony has been directed.—The amount of alimony which the court will award *pendente lite* depends on the circumstances of the case and of the parties. It is larger when the wife is plaintiff than when she is defendant, but even in that case the court takes into consideration the fact that she has not yet proved her allegations. It will be less or more according to her condition in life and her needs. It will be less if she has a separate estate, and it may be increased or perhaps reduced from the amount first fixed, as the circumstances of the parties may change; and, as a rule, alimony pending the suit is always much smaller than the permanent provision made after divorce. In England the proportion of the joint income allowed as alimony is ordinarily, and apart from special reasons either way, about one fifth. In New

York the courts have been disposed to allow the woman no more than her actual wants require until the final adjudication upon the merits, when the permanent alimony may be fixed from the beginning of the case, and the amount of temporary alimony paid meantime is deducted from it. Nor as to permanent alimony is there any fixed rule governing the amount of it. In England it seems to be the common practice to award one third of the husband's income. American courts have settled upon no customary proportion, though there are numerous cases reported in which the allowance has been fixed at rates between one fourth and one half. The amount is discretionary, and nothing more definite can be said than that it is the design to give such amount as the wife ought to have, regarding all the circumstances, if the marital relation had not been broken up. By the statutes of most of the states, the wife is entitled, especially in absolute divorcees, to recover whatever property she brought to the husband upon the marriage.—The fund out of which alimony is to come is ordinarily the husband's income. The court does not, except when special statutes permit the return of the wife's estate to her, or make similar provisions, turn over to her any specific property. Upon the principle that it is the income which is to respond, it cannot on the one hand avail the husband that he has no invested or permanent property, but his earnings must supply the allowance; and on the other hand, the husband's mere expectations of inheriting property are alike immaterial. The husband's indebtedness should also be taken into account in ascertaining his substantial income and resources.—As the demand or grant of alimony is properly collateral to the principal relief, that of separation or divorce, sought in the action, and as the allowance is not decreed—at least permanent alimony is not—unless the principal relief sought is granted, the application for such maintenance is ordinarily only incidental to the principal suit. It is commonly made upon a special petition, or allegation of faculties, as the proceeding is termed in England, in which the husband's pecuniary resources are alleged; this he meets with an answer or other counter proof, and the allegations on both sides may be passed upon by the court, or referred for more careful examination to one of its officers, as a master in chancery or a referee.—The remedy for enforcing the payment of alimony, when the order of the court regarding it is disobeyed, may be by proceedings against the husband for contempt, or, according to the practice in different states, execution may issue for the amount in arrears, or an action of debt may be brought; and in the federal courts it has been held that a bill in equity will lie. In some states, again, the charge of alimony becomes a lien on the husband's real estate, or the court may compel him to give security for its prompt payment, or in a proper case the husband may even be restrained by injunction from so dis-

posing of his property as to place it beyond the reach of the court.

ALISON, Archibald, a Scottish clergyman and author, born in Edinburgh, Nov. 13, 1757, died there, May 17, 1839. He was educated at the university of Glasgow, and at Balliol college, Oxford, took orders in the church of England, and married the daughter of Dr. John Gregory, professor in the university of Edinburgh. In 1790 he obtained the perpetual curacy of Kenley in Shropshire, and afterward several other preferments in the same county. There he lived happily and tranquilly, with mingled literary and pastoral labors, till 1800, when he removed to Edinburgh for the education of his children, and became senior minister of St. Paul's chapel, in York place, where his eloquence soon attracted the attention of the cultivated society of the metropolis. In 1831 increasing years and failing health obliged him to withdraw from public duties. The first edition of his "Essays on the Nature and Principles of Taste," published in 1790, though highly esteemed within a limited circle of men of culture, had been issued in too expensive a style for general circulation. A second edition, with additions, published in 1811, became popular. In 1814 Mr. Alison published two volumes of sermons, which passed rapidly through five editions, and were republished in America.

ALISON, Sir Archibald, Bart., a British historian, eldest son of the preceding, born at Kenley, Shropshire, Dec. 29, 1792, died near Glasgow, May 23, 1867. He was educated in the schools and university of Edinburgh, was called to the bar in 1814, and availed himself of the first income from his practice to travel in Europe. In 1822 he was appointed deputy advocate general, in 1828 member of the crown council, and in 1834 sheriff of Lanarkshire. His first publication was a work on the "Principles of the Criminal Law of Scotland" (1832), followed the next year by the "Practice of the Criminal Law." These books became standard authorities with the Scottish bar. The first volume of his "History of Europe, from the Commencement of the French Revolution to the Restoration of the Bourbons," appeared in 1839, and the work was completed in 10 volumes in 1842. It ran through numerous editions in England, in 12, 14, and 20 volumes, was reprinted in America, and translated into French and German, and even into Arabic (Malta, 1845) and Hindostanee. The author is said to have conceived the plan of this history in his youth, and to have cherished his purpose during 15 years of travel and study, and 15 more of composition. The author was a staunch tory, and his work is considered deficient both in accuracy and impartiality by the English liberals. Mr. Alison for many years contributed articles to "Blackwood's Magazine," a selection of which was published under the title of "Essays, Political, Historical, and Miscellaneous" (3 vols., 1850). He also wrote "Principles of Population" (2 vols.,

1840), combating the theory of Malthus; "England in 1815 and 1845, or a Sufficient or Contracted Currency" (1845); and a "Life of the Duke of Marlborough" (2 vols., 1847). He wrote a continuation of his "History of Europe" to the accession of Louis Napoleon in 1852, of which a second edition was published at Edinburgh in 8 vols. (1863-'5). Mr. Alison was elected rector of Glasgow university in 1851, and received the honorary degree of D. C. L. from the university of Oxford; and soon after the formation of the Derby-Disraeli ministry, June 25, 1852, he was created a baronet.

ALIZARINE, the coloring principle of madder, so called from *alizeri*, the name by which that plant is known in the Levant. Madder is the root of several species of *rubia*, among which the *rubia tinctorum* is the most valued for its dyeing properties. This grows in Asia Minor, Holland, Alsace, and in the south of France and of Russia, and has been cultivated to some extent in Delaware and Ohio. A species native to England is the *rubia peregrina*. This belongs to the order *rubiaceae*, the native members of which, as the galliums, are mostly inconspicuous wild plants. Some of the foreign species are, on the contrary, important plants, such as the cinchona, ipeacacuanha, and coffee plants, and these are distinguished for the number and variety of the peculiar principles which they yield, as quinine, cinchonine, caffeine, and alizarine.—In spite of the numerous investigations that have been made of madder, chemists are still in doubt as to the nature of many of its constituents. Some attribute its coloring powers to the presence of at least two substances, alizarine and purpurine; while others say that only one of these produces the true madder colors. Alizarine was discovered and obtained from madder, as a crystalline sublimate, by Robiquet and Colin, in 1831; but little importance was attached to this discovery until Schunck in 1848 showed that all the finest madder colors contain only alizarine combined with bases and fatty acids. The second coloring matter, termed purpurine, was discovered by Persoz. It contributes to the full and fiery red colors in ordinary madder dyeing, but dyes a bad purple, alizarine being essential to the latter. Purpurine disappears during the purifying processes of soaping, &c., being far less stable than alizarine. It is distinguished from alizarine by its solubility in boiling alum liquor. These two coloring principles may likewise be easily distinguished by the spectrum, alizarine producing a set of dark absorption bands, quite different from those of purpurine, which again vary according to the nature of the solvent. Alizarine can be obtained in yellow needle-shaped crystals by simple sublimation from the dried madder; but this coloring matter is, singularly enough, not contained really formed in the fresh madder root, but is the product of a peculiar decomposition. A crystalline glucoside, termed rubianic acid (Schunck), is contained in the root, and it is this which splits up

simply into alizarine and glucose. This acid crystallizes in fine yellow needles, and gives a definite and crystalline potash salt, from which it was shown to contain 26 atoms of carbon in the molecule. Hence, as no other product but glucose is formed, it follows that alizarine must contain $C_{26} - C_{12} = C_{14}$. The formation of alizarine in extracts of madder root is effected by fermentation peculiar to the plant, and called erythrozone. It is *sui generis*, since no other ferment produces the same effect. When mixed with a solution of rubian or rubianic acid, at the ordinary temperature, the latter is rapidly decomposed as with acids. This is what takes place in making *fleur de garance*. Dyers raise the temperature of their madder baths gradually up to the boiling point, because the application of a high temperature destroys the ferment. When the temperature is gradually raised, the ferment acts upon the glucoside, and produces alizarine. According to Schunck, the origin of purpurine, and its relation to alizarine, are still (1870) involved in obscurity. The formula assigned to alizarine by some chemists is $C_{16}H_6O_3 + 2H_2O$; while Gräbe and Liebermann prefer $C_{14}H_2O_4 + H_2O$.—**Artificial Alizarine.** In studying the transformations of alizarine under the action of chemical reagents, Messrs. Gräbe and Liebermann in 1869 were led to connect it with anthracene, one of the coal-tar series of bodies (see ANTHRACENE), and to devise a mode of forming it artificially. This is justly regarded as one of the most important as well as beneficent discoveries of the age; important as affording a new source for a valuable dye, and beneficent as restoring to agriculture large tracts of land now devoted to the culture of the madder root. The method employed by Gräbe and Liebermann in the artificial production of alizarine is as follows: One part of anthracene is heated with four parts of sulphuric acid, of sp. gr. 1.845, for three or four hours, to a temperature of 212° C., and then for about an hour at 300° C. The mixture is allowed to cool, and to it is added water equal to three times the weight of the anthracene employed, and manganese equal to four times that weight. The whole is boiled for three hours, and milk of lime added, which gives rise to a deposit consisting of the excess of lime and manganese used, and protoxide of manganese, while there remains in solution a double sulphate of anthraquinone and lime. The solution is now acted upon by carbonate of soda in excess; carbonate of lime separates, and the salt of soda thus produced is evaporated to dryness. The solid mass is then mixed with two or three parts of caustic soda and a little water, and heated under pressure in suitable vessels, at a high temperature, whereby the anthraquinone is further oxidized and converted into alizarine. The alkaline mass, on cooling, is dissolved in water and sulphuric or acetic acid added in slight excess, when an orange-yellow flocculent substance precipitates,

which, when perfectly washed and dried, is artificial alizarine. The artificial product appears to be entirely identical with the coloring matter obtained from the madder root. Both the natural and the artificial products crystallize in needles and dissolve in caustic alkalies, forming violet solutions of the same tint and possessing precisely the same tinctorial value. Applied to mordanted fabrics, they produce exactly the same colors, and they resist equally well the action of light. If an adequate supply of anthracene can be obtained, the artificial production of alizarine bids fair to become an established industry of great importance.

ALKALI (Arabic, *al-qali*, the ashes of the plant glasswort, yielding soda), the general name of a class of substances, such as caesia, rubidia, potash, soda, lithia, and ammonia, whose distinguishing peculiarities are solubility in alcohol and water, uniting with oils and fats to form soap, neutralizing and forming salts with acids, reddening several vegetable yellows, and changing reddened litmus to blue. These properties are the reverse of those of acids, and the two classes are regarded as antagonistic to each other. Some other substances, as lime, baryta, strontia, and magnesia, possessing some of the qualities of the alkalies as neutralizing acids, and changing the vegetable colors, are called alkaline earths. Pure anhydrous alkalies are exceedingly caustic, destroying vegetable and animal tissues. They abstract moisture rapidly on exposure to the air. Combined with carbonic acid and water, forming carbonates, they are used in medicine as diuretics and for correcting acidity, as well as for other effects. The alkalies and the earths also were until the present century regarded as simple substances. Lavoisier first suggested that they were metallic oxides. Sir Humphry Davy proved this in 1807, by separating the metals, to which he gave the names potassium, sodium, barium, strontium, and calcium, the last the metallic base of lime. The discovery of these metals led to that of pure potash and soda. The alkalies were known before only in the state of hydrates, though incorrectly regarded as anhydrous.

ALKALIMETRY, the process employed to estimate the quantity of alkali present in any mixture. Its principle consists in exactly neutralizing a certain weight of the alkali, and knowing the quantity of acid of a given strength which is required to effect this. The alkaline substance, carefully weighed, is dissolved in warm water, placed in an alkaliometer, which is usually a graduated glass tube, and diluted sulphuric acid cautiously and slowly added till the solution is made neutral. This is known by the use of little bits of test paper in the liquid, which, by their change of color, indicate the slightest acid or alkaline reaction. The process may be reversed to test the strength of acids, and is then called acidimetry.

ALKALOID, vegetable alkali, a name given to vegetable extracts possessing the property of

uniting with acids to form salts in the same manner as ammonia. The first alkaloid was discovered by Sertürner in 1804 in opium; but little importance was attached to the announcement, and it was not till 1817 that the real value of morphine was demonstrated and the existence of vegetable alkalies fully shown. Since that time the list of alkaloids has rapidly increased, until at the present time (1872) they number more than 100. There are two classes, volatile liquids and permanent solids. The former contain simply carbon, hydrogen, and nitrogen, and only three of them are known, coniine, nicotine, and sparteine. The solid and most numerous alkaloids contain carbon, hydrogen, nitrogen, and oxygen. The organic bases are colorless and generally crystalline. They are insoluble or slightly soluble in water, the best solvent being alcohol. Ether dissolves some of them; chloroform and the hydrocarbons are also good solvents. They generally possess powerful medicinal properties. Numerous artificial alkaloids have been formed, the most important of which is aniline. The natural base coniine has also been made artificially. Some of the best known of the vegetable alkaloids are nicotine, quinia, morphia, strychnia, brucia, aconitina, atropia, and caffeine.

ALKANA. See **HEXNA.**

ALKANET, the commercial name of two different plants. True alkanet consists of the roots and leaves of the *Lawsonia inermis*, which grows wild in the Levant. The leaves pulverized and made into a paste yield a yellow dye. The root, which contains a red pigment, is used as a cosmetic. False alkanet (*oreanette*, *radix aleanna spuria*) is the root of *anchusa tinctoria*, which grows in France, Spain, Italy, Hungary, and Greece. It is inodorous, has a faint, somewhat astringent taste, and colors the saliva. It is used in dyeing goods previously prepared with alum mordants for violet, and iron mordants for gray. The mordanted linen or cotton goods are dipped in an alcoholic extract of the root. It is also used for dyeing silk, but not wool. The coloring matter is called anchusine. The violet and gray colors are brilliant.

ALKINDI, or **Alchinds**, an Arabian physician and philosopher, born in Bassorah at the end of the 8th century, died in the middle of the 9th. Some, however, place his life two or three centuries later. He wrote more than 200 different treatises on logic, music, geometry, arithmetic, astronomy, medicine, &c. His treatise known under the Latin title *De Theoria Magicarum Artium* has secured for him the fame of a magician. Various other works of his were translated into Latin during the middle ages, and published at Paris, Strasbourg, and Venice. His theories are distinguished by great ingenuity, so much so that Cardan ranked him among the twelve subtle spirits of the world.

ALKMAAR, a well built and strongly fortified town of the Netherlands, in North Holland, on

the Helder ship canal, about 18 m. N. by W. of Amsterdam; pop. in 1867, 11,609. Its environs are laid out in beautiful gardens and fine meadows, and broad canals intersect its streets, the banks of which are planted with trees. A court of first resort and a tribunal of commerce sit in Alkmaar, and the town is well supplied with educational and scientific institutions. There is a large export trade in cheese and butter, and a considerable trade in cattle and corn. The manufactures consist of sail cloth, parchment, salt, soap, vinegar, leather, and earthenware. Alkmaar successfully stood a siege of ten years by the Spaniards, from 1573 to 1583; and in the expedition of 1799 the British and Russians, under the duke of York, halted here, before the conclusion by the latter of his inglorious capitulation with the French.

ALKMAAR, Heinrich von, a poet of the 15th century, a native of Alkmaar, celebrated principally in connection with his supposed authorship of the famous poem *Reineke Vos* or *Reineke Fuchs*; but, from Alkmaar's own statements in his preface, it seems probable that he only compiled the poem.

ALKORAN. See KORAN.

ALLAH (Arab. *al*, the, and *Illah*, God), the Mohammedan name of the Supreme Being. The unity of the Deity is the great postulate of the Mohammedan creed. His attributes are thus summed up by the Koran: "There is no God but God. This only true, great, and most high God has his being through himself; is everlasting; is not begotten and begetteth not; is all-sufficient in himself; fills the universe with his infinity; is the centre in which all things unite, as well the hidden as the manifest; is Lord of the world of bodies and spirits, creator and ruler, almighty, all-wise, all-loving, merciful; and his decrees are unchangeable." Mohammedans repeat a rosary of the 99 epithets of the Supreme Being, closing it with the great, all-including name of Allah. *Allah akbar* (God is great) is a battle cry of the Moslem, while *Bism-Allah* or *Bism-Allah* (in the name of God) is the grace before meat of the pious and the invocation at the commencement of every literary performance.

ALLAHABAD. I. A division of the Northwestern Provinces of British India, bounded N. by Agra and Oude, E. by Behar, S. by Gundwana, and W. by Malwah; area, 11,826 sq. m.; pop. about 3,800,000. It is one of the richest provinces of Hindostan. **II.** A district of the preceding division, between lat. 24° 49' and 25° 44' N., and lon. 81° 14' and 82° 26' E.; area, 2,788 sq. m.; pop. about 1,400,000. A part of the district is included in the great plain of the Doab, and the surface generally is nearly level. It is abundantly watered by the Ganges, the Jumna, and some artificial water-courses, produces timber, maize, cotton, flax, indigo, and sugar, and exports salt. **III.** The chief town of the district and province, and since 1862 capital of the Northwestern Provinces, situated at the confluence of the Ganges

and Jumna, and on the East Indian railway, lat. 25° 26' N., lon. 81° 55' E., 75 m. N. W. of Benares; pop. about 65,000, including suburbs. The Hindoos, who call the town Prayaga, regard it as the holiest of all places, and immense numbers of pilgrims visit it annually to bathe at the junction of the two rivers. It was also regarded by the Mohammedans as so sacred that, on coming into possession of it, they named it "God's place" (*Allah abad*). It contains some interesting shrines and ruins, and an ancient castle, converted into a fort and great military depot for Upper India. The native town is inconsiderable, but the European quarter is well built, and the British government since the sepoy rebellion has planned extensive improvements, which will render Allahabad a great military and commercial post. Some have identified the city with the Palibothra of Greek and Roman geographers. It was fortified by Akbar, and on the dismemberment of the empire of Delli was seized in 1753 by the vizer of Oude, from whom it was taken by the British in 1765; it was afterward transferred to the nawab of Oude, and finally ceded to the East India company in 1801. It was then in a very ruinous condition. A sepoy regiment mutinied here June 6, 1857, and killed several of their officers. The rest of the Europeans defended themselves in the fort until relieved by Col. Neill, but the town was nearly destroyed.

ALLAMAKEE, a county forming the N. E. extremity of Iowa, bordering on Minnesota, and separated from Wisconsin by the Mississippi river; area, 667 sq. m.; pop. in 1870, 17,868. It is intersected in the N. by the Upper Iowa, and in the S. by the Yellow river. The soil is productive, and the surface undulating woodland and prairie. The productions in 1870 were 675,448 bushels of wheat, 331,035 of corn, 2,399 of oats, 25,474 of barley, 73,512 of potatoes, and 18,873 tons of hay. Capital, Lansing.

ALLAMAND, Jean Nicolas Sébastien, a naturalist, born in Lausanne in 1713, died in Leyden, March 2, 1787. He was professor of philosophy and natural history at the university of Leyden, member of the London royal society, and of the Haarlem academy of sciences. The Dutch sailors collected for him, in their expeditions into distant countries, specimens of plants, animals, and fossils, which he placed in the botanic garden and museum of the university, which were under his care. He devoted much time to the study of electricity, and was the first to explain the phenomena of the Leyden jar. The shrub *Allamanda*, a native of South America, is called after him. He was the literary executor of 'sGravesande and Prosper Marchand, and, besides editing their unpublished works, translated and edited many English books.

ALLAN, David, a Scottish painter and engraver, born at Alloa, in Clackmannanshire, Feb. 13, 1744, died in Edinburgh, Aug. 6, 1796.

In 1755 he entered as an apprentice the art academy of Robert Foulis in Glasgow, and in 1764 went to Rome, where in 1773 he obtained from the academy of St. Luke the gold medal for the best historical drawing. His earliest humorous productions were four sketches of the carnival at Rome. He settled in Edinburgh; and in 1786, after the death of Runciman, he was appointed master of the academy of arts. About the same time he commenced 12 illustrations of Allan Ramsay's "Gentle Shepherd," which he subsequently engraved in aquatint. He also made some designs from the lyrics of Burns.

ALLAN, Sir William, a Scottish historical painter, born in Edinburgh in 1782, died Feb. 22, 1850. Failing to obtain patronage in London, he went to Russia, where he spent ten years, and made visits to the Crimea, Circassia, and Turkey. In 1814 he returned to Edinburgh, where he became intimate with Sir Walter Scott, through whose influence his picture of the "Circassian Captives" was purchased by subscription for 1,000 guineas. In 1841 he once more went to St. Petersburg, where he executed for the emperor a painting of "Peter the Great teaching his Subjects the Art of Ship-building," now in the winter palace. In 1826 he was made an associate of the royal academy at London, and in 1835 an academician. He was president of the royal Scottish academy from 1838 till his death.

ALLAN-KARDEC, Hippelyte Léon Dénizard, a French spiritualist, born in Lyons, Oct. 3, 1803, died April 1, 1869. He established in 1858 a periodical review on spiritualism (*Revue spirite*), and the *société parisienne des études spirites*. His principal works are: *Le livre des esprits* (2 ed., 1860); *Le livre des médiums*; and *L'imitation de l'Évangile selon le spiritualisme* (1864).

ALLARD, Jean François, a French soldier, born at St. Tropez, Provence, in 1785, died in Peshawar, Jan. 23, 1839. In 1815 he served on the staff of Marshal Brune, after whose murder he went to Egypt, and thence to Persia, where he entered the service of Abbas Mirza. In 1820 he went to Lahore, and took service under Runjeet Singh, by whom he was finally made commander-in-chief of his army. He organized and disciplined the troops after the French model, and gained many victories. In 1835 he revisited France, accompanied by his family, and was received with distinguished honors, Louis Philippe appointing him chargé d'affaires in Lahore.

ALLARDICE, Robert Barclay. See BARCLAY.

ALLEGAN, a W. S. W. county of Michigan, on Lake Michigan; area, 840 sq. m.; pop. in 1870, 32,165. The Kalamazoo river (navigable by small steamboats) intersects it, and it is drained by the Black and Babbit rivers. The soil is a deep black alluvium on the river margins, and in some other parts sand and clay predominate; the surface is undulating and mostly covered with forests. In the S. W. part is a quarry of

good limestone. Several lines of railroad traverse the county. The productions in 1870 were 338,243 bushels of wheat, 376,974 of corn, 205,219 of oats, 20,973 of barley, 267,795 of potatoes, 129,223 lbs. of wool, 476,065 of butter, 127,336 of maple sugar, and 27,453 tons of hay. There were 167 school houses. The capital, Allegan, is built on both sides of Kalamazoo river, 145 m. W. by N. of Detroit, and has a considerable trade in lumber.

ALLEGANY. I. A W. S. W. county of New York, bordering on Pennsylvania; area, 1,045 sq. m.; pop. in 1870, 40,814. The Genesee river and its tributaries furnish motive power for numerous mills. On each side of the Genesee valley the country rises until it becomes table land in the E. and W. parts. The productions in 1870 were 195,721 bushels of wheat, 800,600 of oats, 16,434 of rye, 135,850 of corn, 96,554 of buckwheat, 29,558 of barley, 384,687 of potatoes, 492,568 lbs. of maple sugar, 410,168 of wool, 1,908,721 of butter, 220,880 of cheese, and 134,797 tons of hay. There are numerous saw and grist mills, tanneries, &c. Bog iron ore and limestone are obtained. The New York and Erie railroad and the Genesee canal pass through the county. Capital, Belmont. **II.** A W. county of Maryland, bordering on Virginia and Pennsylvania, bounded by the Potomac and its north branch; area, 800 sq. m.; pop. in 1870, 38,536, of whom 1,166 were colored. The Youghiogheny river intersects its W. part, and it is drained by several creeks. The main Alleghany mountains and several smaller ridges traverse it, and its surface is rocky and broken. Limestone, sandstone, iron ore, and coal abound, the last being extensively mined at Cumberland. The glades or valleys in the mountains furnish the celebrated glades butter and mutton. The Baltimore and Ohio and Pittsburgh and Connellsville railroads and the Chesapeake and Ohio canal pass through the county. The productions in 1870 were 70,404 bushels of wheat, 45,090 of rye, 116,062 of corn, 206,589 of oats, 47,935 lbs. of wool, 337,639 of butter, and 70,454 of maple sugar. There are numerous manufacturing establishments. Capital, Cumberland.

ALLEGHANY. I. A W. county of Virginia, bordering on West Virginia, and bounded N. W. by the main chain of the Alleghanies and S. E. by Middle mountain; area, 500 sq. m.; pop. in 1870, 3,674, of whom 579 were colored. Jackson's river unites with Cow Pasture river on the E. border to form the James. The passage of Jackson's river through one of the mountains affords fine scenery. Peters and the Warm Spring mountains extend through the centre of the county. Iron ore is found, and the Red Sweet Springs have some celebrity. The Virginia Central railroad terminates at Covington, and the Chesapeake and Ohio railroad begins there. The productions in 1870 were 24,843 bushels of wheat, 50,695 of corn, 31,991 of oats, 25,747 lbs. of tobacco, and 40,690 of butter. Capital, Cov-

ington. **H. A. N. W.** county of North Carolina, bordering on Virginia, bounded W. by New river, a branch of the Kanawha, and E. and S. by the Blue Ridge mountains; area, 300 sq. m.; pop. in 1870, 3,691. There are mines of copper. The productions in 1870 were 7,988 bushels of wheat, 43,369 of corn, and 21,496 of oats. Capital, Gap Civil.

ALLEGHANY COLLEGE. See MEADVILLE.

ALLEGHANY MOUNTAINS. See APPALACHIAN MOUNTAINS.

ALLEGHANY RIVER rises in Potter county, N. Pennsylvania, flows circuitously westward through New York, returns to Pennsylvania, and after a southerly course unites at Pittsburgh with the Monongahela river to form the Ohio. It flows through a hilly country, abounding in pine forests and coal. The river is navigable for small steamboats to Olean, N. Y., 240 m. from its mouth and about 45 m. from its source, and to Waterford, Pa., on French creek, its principal tributary, 14 m. from Lake Erie. Its chief tributary from the east is the Conemaugh. The principal towns along its course are Warren, Kittanning, Franklin, and Oil City. The Alleghany separates Pittsburgh from Allegheny City.

ALLEGHENY, a S. W. county of Pennsylvania; area, 750 sq. m.; pop. in 1870, 262,204. Near the centre of the county the Ohio is formed by the confluence of the Alleghany and Monongahela rivers. The Youghiogheny and several creeks also drain it. Near the rivers the surface is broken into ravines; most of the upland is hilly and very picturesque. Nearly all of the county is arable. The productions in 1870 were 325,331 bushels of wheat, 674,916 of corn, 1,111,269 of oats, 78,372 of rye, 69,946 of barley, 769,144 of potatoes, 308,475 lbs. of wool, 1,223,744 of butter, and 64,730 tons of hay. Bituminous coal is found in the county, and iron, glass, wool, &c., are extensively manufactured. The valuation of personal property in 1870 was \$12,367,611. Allegheny is the second county in importance in the state. Capital, Pittsburgh.

ALLEGHENY CITY, a manufacturing city of Allegheny county, Pa., opposite Pittsburgh, on the W. side of the Alleghany river, at its junction with the Monongahela; pop. in 1860, 28,702; in 1870, 53,180. The city contains many elegant residences of persons doing business in Pittsburgh. It has one weekly newspaper, and one semi-monthly and one monthly periodical. The Western theological seminary of the Presbyterian church was established here in 1827. Before the union it was under the control of the Old School Presbyterians. In 1863 there were 5 professors and 70 students, 935 graduates, and the endowment amounted to \$184,800. The theological seminary of the United Presbyterian church, established in 1826, and the Allegheny theological institute, organized in 1840 by the synod of the Reformed Presbyterian church, are also situated here. In 1868 the former had 3 professors, 36 stu-

dents, 426 graduates, and 2,000 volumes in the library. The western penitentiary, an immense building in the ancient Norman style, situated on the "common" of Allegheny City, was completed in 1827 at a cost of \$183,000. In 1868 it had 463 inmates, employed in weaving, shoemaking, and the manufacture of cigars; earnings, \$27,013. The city contains 12 schools, 2 national banks, 10 savings banks, 1 real estate bank, and 1 trust company; 4 rolling mills, employing 1,155 hands; 5 cotton mills, with 1,050 hands; 11 ale and beer breweries, averaging 20 men each; 6 founderies and machine shops, averaging 30 men each; 1 blast furnace, with 70 men; and 1 steel factory, with 250 hands. The Pittsburgh locomotive works employ 380 hands and complete one locomotive a week. There are 45 churches, of which 16 are Presbyterian, 9 Catholic, 8 Methodist, 3 Baptist, 3 Lutheran, 2 Episcopal, and 1 each Congregational, Disciples', and Reformed. The charitable institutions are the home for the friendless, the widows' home association, the house of industry, and the orphan asylum. There is a soldiers' monument which cost \$37,000. The city park contains an area of 100 acres. The assessed value of property in 1871 was \$8,434,636.

ALLEGIANCE (Lat. *aligare*, to bind to), the subject's duty of obedience to the sovereign under whose protection he is. Allegiance is correlative with protection, and the duty of allegiance is in return for and in consideration of the fact of protection. Therefore, when the sovereign can no longer protect the subject, his allegiance ceases; and on this principle the duty is discharged by conquest or by cession of the sovereign's territory by treaty. Natural allegiance arises from the fact of birth within the territorial domain and actual protection by the sovereign. But actual allegiance is due even by an alien to the sovereign of the state in which he is; though, by comity of nations, there is an exception to this rule in favor of foreign sovereigns and ambassadors and their suites, and of the officers and crews of foreign war ships, and of foreign armies when they are permitted to pass through the state. As allegiance is the highest of the citizen's obligations, so the violation of it is the highest of crimes, or treason. The principle that allegiance is due to the actual sovereign has been carried so far as to make acts treasons though they were done against a usurper; and Blackstone says that on this ground, after Edward IV. recovered the crown, treasons committed against Henry VI. were capitally punished, though Henry had been declared a usurper by parliament. On the other hand, but on the same principle at common law, and until a statute was passed for their naturalization, the children of English subjects born abroad, that is, out of the king's domain and protection, were aliens. But the most important quality attached by the common law to the doctrine of allegiance was that it was indissoluble. The principle was shortly expressed in the familiar

Latin maxim, *Nemo potest exuere patriam*, "No one can abjure his country," or renounce the fealty which he owes to his sovereign. The maxim is as old as English jurisprudence, and until the most recent period the rule has been maintained in England to its fullest extent. It has nowhere else been asserted, in modern times at least, with the same rigor with which it was enforced there; and even while it stood the acknowledged rule of the law of England, it was condemned by many of its soundest jurists. One of them, Twiss, has very lately said of it that it found no countenance in the law of nations, but was on the contrary in direct conflict with incontestable principles of that system. Observing the more liberal tone of modern public law upon this subject, it is worth notice that it is now asserting only the doctrine which was maintained by the law of Rome in its best period. In his argument for Balbus Cicero declared it to be even the firmest foundation of Roman liberty that the citizen might retain or renounce his allegiance at his pleasure. But the English common law asserted that allegiance intrinsic and absolute arose from the mere fact of birth within the sovereign's dominion and protection; that it could not be cancelled or forfeited by any change of time, place, or circumstances; that the subject could not abjure it or renounce it by abandoning the realm, nor by swearing loyalty to another state; nor could it be released in any way without the concurrence of the supreme legislative power. Coke expressed the rigor of the rule as it was held in England in his time, and indeed for more than two centuries afterward, when he said that "all subjects are equally bound to their allegiance as if they had taken the oath of it, because it is written by the finger of the law in their hearts." As has just been said, however, this supreme duty might be released by the consent of the sovereign. Such an assent was given, for example, in the case of the United States, when by treaty our independence was recognized by Great Britain; and after that it was several times decided in England that persons, though born here British subjects, who adhered to the new state, ceased to be subjects of the crown and became aliens. But though steadily asserting the rule that allegiance was indissoluble, England has nevertheless practically conceded its invalidity by admitting and naturalizing foreigners into her citizenship, just as all other countries have done.—In modern times at least, no other considerable European state has enforced the theory of the common law, or at least not with the severity with which it was enforced in England. The French code declares expressly that the quality of a Frenchman is lost by naturalization in a foreign country, and France, Spain, and most of the German states have enacted laws regulating the naturalization of foreigners. The great European authorities in public law, Grotius, Pufendorf, Vattel, and others, concede in general terms

the right of expatriation, qualifying it only when it is restrained by law, or when the citizen owes to his native state some already assumed but not yet discharged obligation; if, for example, he has violated the law and owes the penalty, or is invested with some public trust, or war threatens and his sovereign needs his aid; and these have been the chief modifications of the right to renounce allegiance which have been discussed in our own diplomatic correspondence upon this subject with European states. When once naturalization is admitted to be competent and right, the right of expatriation and of renunciation of the former allegiance should seem to be implied as a necessary corollary. Naturalization means the complete adoption of a foreigner and the investing him with the actual citizenship of his adopted country. In practice it compels, as a precedent condition, his entire renunciation of his former allegiance, and the assumption by solemn oath of an exclusive fidelity to the new sovereign; and, with one or two modifications only, it gives him the same rights which he would have had if he had been born within his dominion and protection. The status which he thus receives is clearly inconsistent with any allegiance to the country of his birth. Allegiance cannot be divided, and if his original allegiance has not been utterly cancelled, then the naturalization is an empty form, and the adopted citizen has not the right to protection and citizenship which the new sovereign pretends to guarantee to him. These considerations have been brought forward in most of the cases which have arisen from time to time in the United States. In the earlier cases, however, though the courts inclined to give them their just weight, they repeatedly evaded direct decision of the question. From an historical review of all the cases which had arisen down to his time, Chancellor Kent declared the prevailing spirit of the decisions to be that, in the absence of any legislation sanctioning the abjuration of allegiance, the rule of the common law remained unaltered. But in one instance at least, as early as 1812, our government assumed a position on this question quite as advanced as it has ever taken in the cases which have arisen since that time. During the war with England then existing, the prince regent announced that every native-born Briton, taken prisoner while fighting in the American army, should be executed for treason to his lawful sovereign. Mr. Madison announced in return, that if any naturalized citizen of this country were put to death on the pretence that he was a British subject, the United States would put to death two English prisoners in retaliation. There was no further discussion on the subject, and no occasion for any. Still later, and especially within the last twenty years, cases have occurred in which foreigners naturalized here were upon their return to their native states compelled to render military service there, or

were otherwise forced to assume the duties of subjects of their states of birth, and they invoked the protection of the United States by virtue of their status as American citizens. In 1857, in the case of Ernst, a subject of Hanover, naturalized here, who on his return was forced into the Hanoverian army, Attorney General Black gave to the president a very clear and convincing opinion, in which he advised him that Ernst was an American citizen; that by the public law of the world we have the undoubted right to naturalize a foreigner, whether his natural sovereign consents to his emigration or not; and that Hanover could not justify Ernst's arrest, even by showing that he emigrated contrary to the laws of that country, unless it could be proved that the original right of expatriation depended on the consent of the natural sovereign; and as to the last proposition, he added that he was sure that it could not be established. In a case in the same year, that of Amther, Mr. Black's opinion was to the same effect on a reversed state of facts. Amther, a Bavarian subject, after being naturalized here, returned to Bavaria and sought to recover his original status as a citizen of that country. The authorities there doubted whether he could throw off his allegiance to this country, but the attorney general of the United States was of the clear opinion that he could; that by our law any citizen, native or naturalized, might sever his political connection with this government at his pleasure, provided it was for a purpose and at a time which were not injurious to our interests. He was of the opinion, therefore, that Amther might be reinstated as a citizen of Bavaria, and that, as a condition to such restitution of his citizenship, the Bavarian government was at liberty to compel him to abjure his allegiance to the United States in any form that its laws required. Doctrines quite as emphatic were pronounced by Mr. Marey, secretary of state in 1853, in the famous case of Koszta. In a letter to the American minister to Prussia in 1859, concerning cases then in hand, Mr. Cass declared that the right of expatriation could not at this moment be doubted or denied in this country, and that the doctrine of perpetual allegiance was a relic of barbarism which was fast disappearing from Christendom. In 1866 Attorney General Stanbery declined to discuss the general question of the right of expatriation under our law, on the ground that the practice of the United States had long since rendered that question a mere abstraction. It should be observed, however, that our government, in its dealings with other nations on this subject, has not claimed that the right to renounce allegiance is absolute under all circumstances. It has been willing to concede that our naturalization did not give full rights of American citizenship to aliens whose removal from their native country bore the character of an escape or flight from civil or political obligations already fixed upon

them; so that, while it would not recognize any validity in the general right to claim military service, for example, the actual performance of which had not been demanded when the foreign subject left his country, yet it would concede that there was a just force in the claim of the foreign state, when the subject had been already conscripted into the army, and had deserted from it, or had otherwise run away from actually existing obligations. The whole subject has been finally closed, so far as the law of the United States about it is concerned, by a very explicit and vigorous statute passed in July, 1868. Its preamble recites that the right of expatriation is a natural and inherent right of all people, indispensable to the enjoyment of the rights of life, liberty, and the pursuit of happiness; that in the recognition of this principle, this government has freely received emigrants from all nations and invested them with the right of citizenship; that it is necessary for the maintenance of public peace that the claim of foreign allegiance as to such adopted citizens should be promptly and finally disavowed; and it is therefore enacted that any declaration, opinion, order, or decision of any officer of this government which denies, impairs, restricts, or questions the right of expatriation, is inconsistent with the fundamental principles of the government. The statute further enacts that all naturalized citizens of the United States, while in foreign states, are entitled to and shall receive from this government the same protection of person and property that is accorded to native-born citizens in like circumstances. At last, in 1870, Great Britain by the naturalization act of that year (May 12) revised all her own laws upon alienage, expatriation, and naturalization, and for the first time in her history recognized the right of her subjects to renounce their allegiance to the crown. (See NATURALIZATION.)

ALLEGRI, Antonio. See CORREGGIO.

ALLEGRI, Gregorio, an Italian ecclesiastic and composer of church music, born in Rome about 1580, died there in February, 1652. He was the pupil of Nanini, and on terms of intimacy with Palestrina. His voice was not remarkable, but he was a perfect master of harmony, and was made one of the singers in the pope's chapel in 1629. The famous *Miserere*, performed yearly on Wednesday and Friday of Passion Week, in the papal chapel, is his composition.

ALLEINE, or Allein. I. Joseph, an English nonconformist, minister and author, born at Devizes in 1633, died in 1668. He received his education at Oxford, and was a man of extensive literary acquirements. Though ejected from his curacy and imprisoned for nonconformity, he yet preserved his reverence for the ecclesiastical authorities, and his loyalty to the king. His principal work, "An Alarm to Unconverted Sinners," has passed through numerous editions. II. Richard, an English nonconforming clergyman, born at Ditchet, Somersetshire, in 1611, died in 1681. He was educated at Oxford,

and became rector of Batecombe in Somersetshire. He was a rigid puritan, and assisted the commissioners appointed by parliament to purify the church of "scandalous ministers." He was deprived of his rectory after the restoration as a nonconformist, but continued to preach in a private house. Although often censured for so doing, his virtues shielded him from any severity on the part of the authorities.

ALLEMAND, Zacharie Jacques Théodore, count, a French vice admiral, born at Port Louis (island of Mauritius) in 1762, died at Toulon, March 2, 1826. He entered the navy at the age of 12, was one of the first chevaliers of the legion of honor, and was soon after its formation raised to the rank of officer. In various cruises he inflicted immense losses upon English commerce. In 1809 he commanded the squadrons of Brest, Toulon, and Rochefort, in the capacity of vice admiral. The fleet was anchored in the Basque roads (between the islands of Aix and Oléron), when on April 11 Lord Cochrane attacked it with 50 fire ships and several infernal machines invented by Col. Congreve. Allemand saved all but four of his vessels, and the success of the English was very slight, compared to the immense cost of the expedition.

ALLEN, I. A S. county of Kentucky, bordering on Tennessee, bounded N. E. by Big Barren river, and intersected by Trammel's creek; area, 300 sq. m.; pop. in 1870, 10,296, of whom 1,104 were colored. There are several caves and salt springs in the county. The surface is level and the soil moderately fertile. The productions in 1870 were 55,844 bushels of wheat, 390,883 of corn, 96,647 of oats, 747,489 lbs. of tobacco, 133,487 of butter, and 23,635 gallons of sorghum molasses. Capital, Scottsville. **II.** A W. N. W. county of Ohio, intersected by the Auglaize and Ottawa rivers and Riley and Sugar creeks; area, 405 sq. m.; pop. in 1870, 23,623. It has a fertile soil, with a surface generally level and abounding in hardwood timber. The productions in 1870 were 315,164 bushels of wheat, 21,671 of rye, 209,269 of oats, 874,017 of corn, 92,035 lbs. of flax, 125,897 of wool, 466,482 of butter, and 21,173 tons of hay. Several railroads and the Miami canal pass through it. Capital, Lima. **III.** An E. N. E. county of Indiana, on the Ohio line; area, 638 sq. m.; pop. in 1870, 43,494. It is nearly level, with a fruitful soil, and well watered by the St. Joseph and St. Mary rivers, which unite at Fort Wayne and form the Maumee river. It is well wooded with oak, hickory, beech, maple, and other trees. The Wabash and Erie canal passes through the county, which is also intersected by numerous lines of railroad. The productions in 1870 were 432,752 bushels of wheat, 273,344 of corn, 212,944 of oats, 100,930 of potatoes, 106,778 lbs. of wool, 543,322 of butter, and 28,377 tons of hay. Capital, Fort Wayne. **IV.** A new county in S. E. Kansas; area, 504 sq. m.; pop. in 1870, 7,022. The Neosho river flows through

the W. portion of the county. Coal is found, and stock-raising is extensively pursued. The county has railroad communication with Junction City on the Kansas Pacific road, and also with Lawrence. The productions in 1870 were 27,734 bushels of wheat, 187,225 of corn, 115,708 of oats, 23,333 of potatoes, and 90,588 lbs. of butter. There were 29 schools, 3 newspapers, and 12 manufacturing establishments. Capital, Iola.

ALLEN, Bog of. See Bog.

ALLEN, Ethan, an American revolutionary partisan, born in Connecticut in 1739, died in Burlington, Vt., Feb. 13, 1789. About 1763 he settled, with four younger brothers, in the township of Bennington, Vt. Previous to the revolution there existed a dispute between the colonies of New York and New Hampshire relative to their boundaries, and the debatable land included the whole of the present state of Vermont, then called the New Hampshire grants. Ethan Allen first became conspicuous in the controversy which grew out of the attempt to enforce New York law. Actions of ejectment being brought against those who held land under grants from New Hampshire, Allen was selected in 1770 as agent to represent the settlers in the litigation at Albany. The decision was adverse to them, and they resolved to resist. They adopted Allen's own phrase, "The gods of the valleys are not the gods of the hills." The New York authorities were everywhere set at defiance. Allen was made colonel of an armed force which not only protected the New Hampshire grantees, but removed the New York settlers. Governor Tryon of New York proclaimed a reward of £150 for his arrest. This state of affairs remained unaltered till the revolution, New York maintaining her hostile attitude, and the Vermonters the possession of their farms. In 1775, when war with the mother country had become inevitable, the occupation of Ticonderoga was determined on, and the task was confided to Allen, who set out at once at the head of his "Green Mountain Boys," reaching Castleton May 7, 1775. A party was also detached under Capt. Herrick toward Skenesborough, and another under Capt. Douglass to Panton in the vicinity of Crown Point. On the morning of May 10 Allen, who had previously been joined by Arnold, surprised Ticonderoga, summoning Capt. Delaplace, who commanded the post, to surrender "in the name of the great Jehovah and the continental congress." By this *coup de main*, 2 officers, 48 rank and file, 120 pieces of artillery, and a large quantity of small arms, were captured, and the command of the Green mountains was wrested from the English. Only 80 Americans were present at the capture. The other enterprises were equally successful, Skenesborough and Crown Point being also captured. A dispute ensued between Arnold and Allen relative to the command, which the latter maintained until he was relieved by the arrival of the Connecticut regi-

ment, commanded by Col. Hinman, to whom he delivered his conquests. Allen immediately proposed to the authorities of New York an invasion of Canada, which was refused; and he then proceeded to Philadelphia, where the continental congress officially acknowledged his services. He next joined Gen. Schuyler's army as a volunteer, was employed in secret missions to sound the views of the Canadians, and rendered valuable aid in Montgomery's expedition to Canada; but in an unfortunate demonstration against Montreal with a small force of American and Canadian recruits, made on the persuasion of Major Brown, Sept. 25, 1775, he was captured and sent a prisoner to England. A few months later he was sent back to America, and confined in prison ships and jails at Halifax and New York till May 3, 1778, when he was exchanged. During most of his captivity he was treated as a felon and kept heavily ironed, but for a part of 1776-7 was allowed restricted liberty on parole. Kindly received by congress and by Washington, he was about to enter the military service again when the old colonial troubles regarding Vermont were revived. Allen was now chosen general, and appointed to command all the militia of that state. In the mean time 16 of the western townships of New Hampshire sought annexation to Vermont, sending a petition to that effect to the legislature, who referred the matter to the people. The governor of New Hampshire protested against this course, writing to the continental congress to interpose its authority. Allen was sent as the agent of Vermont to explain to congress the course of the state. About this time the English commanders in America began to meditate the restoration of royal authority in Vermont, and, while the Vermont claim to self-government was in abeyance, sought to take advantage of the dispute. A tempting offer was made to Allen through Beverley Robinson, a well known tory of the time, without any result, except that, by feigning negotiations, Allen was able to preserve the neutrality of the English authorities toward his mountaineers, who were consequently unmolested until nearly the end of the war. Before that time he removed to Bennington, thence to Arlington, and subsequently to the vicinity of Onion river, where he resided till his death, serving for some time in the legislature. He was twice married, and left a wife and several children. In addition to a history of the controversy between Vermont and New York, a narrative of his captivity, and various political pamphlets, he was the author of a work entitled "Reason the only Oracle of Man" (8vo, Bennington, 1784), in which the Bible and the Christian religion are assailed from a purely deistic standpoint.

ALLEN, Ira, brother of Ethan, born in 1752, died in Philadelphia, Jan. 7, 1814. He served in the American army during the revolution, although at first a tory, was a member of the constitutional convention of Vermont, and was

the first secretary of the state, afterward treasurer, surveyor general, &c. In 1795 he went to France, where he purchased 20,000 muskets and 24 cannon, expecting to sell them to the state; but while returning home with a portion of them, he was captured and carried to England, under the accusation of furnishing arms to the Irish rebels. A lawsuit of eight years' duration followed, in which he was successful. During this time he published "The Natural and Political History of Vermont" (8vo, London, 1798).

ALLEN, Joseph W., an English landscape painter, born in Lambeth, London, in 1803, died Aug. 26, 1852. He was for a time usher in a school, but soon went to London to study art. At this time he used to paint signs and transparencies to eke out a subsistence, and afterward took up scene painting, finally becoming principal scene painter at the Olympic theatre. He had excelled in depicting quiet rural scenery; but when he began to employ the brilliant effects which should be confined to the stage, the results which he obtained were far inferior to those exhibited in his earlier productions. He was active in the establishment of the "Society of British Artists."

ALLEN, Paul, an American editor and author, born in Providence, R. I., Feb. 15, 1775, died in Baltimore in 1826. After graduating at Brown university, he went to Philadelphia, and was employed to write for the "Port Folio" and the "United States Gazette." In 1801 he published a small volume of poems. He also, about this time, superintended the publication of "Lewis and Clarke's Travels." He became successively the editor of the "Federal Republican" and the "Journal of the Times," but was unsuccessful in both enterprises, sank into extreme poverty, and for a time his reason was obscured. He finally assumed the management of the "Morning Chronicle" at Baltimore, and conducted that journal until his death. In 1821 the "Life of Washington" appeared, published in his name, but really written by John Neal and another of his friends, named Watkins, Allen merely contributing a portion of the preface. His poem of "Noah" was published in 1821, in 5 cantos. It had originally consisted of 25; but, having been placed in the hands of Mr. Neal for revision, he reduced it to its present dimensions.

ALLEN, Samuel, a London merchant and acting governor of New Hampshire, born about 1635, died May 5, 1705. He purchased from Mason's heirs in 1691 a large tract of land in New Hampshire, including Portsmouth and Dover, and extending 60 miles inland. He acted as governor of New Hampshire until the arrival of Lord Bellamont in 1699. His purchase involved him in a protracted lawsuit with the actual settlers, who produced an Indian title, subsequently found to be a forgery, but not until his family had become extinct.

ALLEN, Solomon, an American revolutionary soldier, born in Northampton, Mass., Feb. 23,

1751, died Jan. 20, 1821. He rose to the rank of major during the revolution, commanded the guard which took charge of André on his capture, and assisted in putting down Shays's rebellion at a later period. At the age of 50 he became a clergyman.

ALLEN, Thomas, an American clergyman, born in Northampton, Mass., Jan. 17, 1743, died in Pittsfield, Feb. 11, 1810. He graduated at Harvard college in 1762, and was ordained in 1764 at Pittsfield, of which town he was the first minister. Twice during the war of the revolution he served as chaplain, and in the battle of Bennington he took an active part. He was minister of the same church from the time of his ordination till his death, a period of nearly 46 years, and during this time preached 600 or 700 funeral sermons.

ALLEN, William, D. D., an American clergyman and author, son of the preceding, born in Pittsfield, Mass., Jan. 2, 1784, died in Northampton, July 16, 1868. He graduated at Harvard college in 1802, and studied theology with the Rev. Dr. Pierce of Brookline. After being licensed in 1804 by the Berkshire association, he preached for some months in various parts of western New York. Upon his return he was appointed a regent of Harvard college, and was also assistant librarian of the college. During this period he prepared the first edition of his "American Biographical and Historical Dictionary" (1809), containing notices of about 700 Americans. This was the first book of general biography issued in the United States. In 1807 he prepared the biographical sketches of American ministers for the Rev. David Bogue's and Dr. Bennett's "History of Dissenters," published in London in 4 vols. The second edition of his "Dictionary" appeared in 1832, and contained more than 1,800 names. The third edition, published in Boston in 1857, contains biographies and notices of nearly 7,000 Americans. His connection with the university ceased in 1810, when he was ordained pastor of the Congregational church in Pittsfield, as his father's successor. The legislature of New Hampshire in 1816 altered the charter of Dartmouth college, and created in its stead a university, of which Dr. Allen was made president in 1817. Upon an appeal to the supreme court at Washington, the rights of the college against the state were maintained in 1819. In 1820 Dr. Allen was appointed president of Bowdoin college, Me., and retained that position till 1839, when he resigned it, and retired to Northampton, Mass., engaging in various literary labors. Among these is a collection of more than 10,000 words not found in dictionaries of the English language; nearly 1,500 being contributed to Worcester's dictionary (1846), more than 4,000 to Webster's (1854), and about 6,000 to the new edition of Webster. His other chief writings are: "Junius Unmasked," to prove that Lord Sackville was the real Junius; "Accounts of Shipwrecks;" "Psalms and Hymns," with many original

hymns (1835); memoirs of Dr. Eleazar Wheelock, and of Dr. John Codman (1853); "Wunnissoo, or the Vale of Hoosatunnuk," a poem, with learned notes (1856); "Christian Sonnets" (1860); "Poems of Nazareth and the Cross" (1866); and "Sacred Songs" (1867).

ALLEN, William, an English chemist, born Aug. 29, 1770, died near Lindfield, Sussex, Dec. 30, 1843. He was the son of a Quaker silk manufacturer in Spitalfields, and learned chemistry in the pharmacy of Mr. Bevan, in London, to whose business he eventually succeeded. He was for many years lecturer on chemistry and experimental philosophy at Guy's hospital, a fellow of the royal society, and president and one of the founders of the pharmaceutical society. In conjunction with his friend Mr. Pepys he established the proportion of carbon in carbonic acid, and demonstrated that the diamond was pure carbon. Having purchased an estate in Sussex, he devoted himself for many years to improving the condition of his tenantry and poor neighbors, founding schools, building model cottages, and laying out gardens and playgrounds.

ALLEN, William Henry, an officer of the American navy, born in Providence, R. I., Oct. 21, 1784, died in Plymouth, Eng., Aug. 15, 1813. He was a son of Major William Allen, entered the navy as a midshipman in 1800, and in 1809 was appointed first lieutenant of the frigate United States. Oct. 25, 1812, he distinguished himself in the action between this vessel and the British frigate Macedonian, which resulted in the capture of the latter. He afterward received the command of the brig Argus in 1813, with which he cruised in the neighborhood of England, capturing property to the amount, as was estimated, of \$2,000,000. On Aug. 14 he fought the British brig Pelican, losing the Argus, and himself dying of his wounds the next day.

ALLEN, William Henry, LL. D., an American scholar and educator, born in Readfield (now Manchester), Kennebec county, Me., March 27, 1808. After preparatory study in the Maine conference seminary, he entered Bowdoin college, where he graduated in 1833. From 1833 to 1836 he was teacher of Latin and Greek in Cazenovia seminary, N. Y.; in 1836 principal of a high school at Augusta, Me., where he became a member of the Methodist Episcopal church; from 1836 to 1846 professor of natural philosophy and chemistry in Dickinson college, Carlisle, Pa.; from 1846 to 1849 professor of philosophy and English literature in the same institution, and in 1847-'8 its acting president; from 1849 to 1862 president of Girard college, Philadelphia, and for one year president of the agricultural college of Pennsylvania. In 1867 he was recalled to the presidency of Girard college, which position he now (1873) occupies. In March, 1872, he was chosen president of the American Bible society. President Allen has contributed to the reviews and magazines many articles on philosophical, literary,

and educational questions. He is also the author of numerous addresses and several valuable reports on education. In 1846 he received the honorary degree of M. D. from the Philadelphia college of medicine; and in 1850 the degree of LL. D. from both Union college, New York, and Emory and Henry college, Virginia.

ALLENDE, José, an officer in the Spanish army, of Mexican birth, to whom Hidalgo first intrusted his plan of revolt in September, 1810. Allende was at that time a captain of the Mexican regiment of La Reyna, and brought to the service the military skill of which Hidalgo was so much in need. When the regiment of La Reyna and that of Celaya joined Hidalgo, the native levies gained some consistency, and in the same month achieved the famous capture of the Alhóndega of Guanajuato. After Nov. 29, 1810, Allende joined Hidalgo, and was able to replace the guns which had previously been lost at Aculeo, by bringing others from San Blas, the great naval station of Spain on the Pacific, of which Morelos had obtained possession. Contrary to the advice of Allende, Hidalgo determined to fight the enemy, and was defeated. Allende brought off the fragment of the army, but was arrested near Saltillo by the treachery of an old comrade named Elizondo, and shot at Chihuahua, July 27, 1811.

ALLENTOWN, capital of Lehigh county, Pa., on the W. bank of Lehigh river, 18 m. above its junction with the Delaware, and 59 m. by railroad N. N. W. of Philadelphia; pop. in 1860, 8,025; in 1870, 13,884. In 1762 the town was laid out and called Northampton, the name of the county it then belonged to. It contained 13 families. In 1776 there were 54 houses, of which 7 were taverns. In 1812 Lehigh county was established and Northampton was made the county town, having been incorporated as a borough the year previously. In 1838 the name was changed to Allentown. By a railroad extending up and down the valley of the Lehigh, it is connected in one direction with the anthracite coal region at the head waters of this stream, and in the other with New York and Philadelphia. Another railroad 36 m. long connects the Lehigh valley with that of the Schuylkill above Reading, and affords the most direct line of communication between New York city and the southwest. By these railroads and the Lehigh canal, Allentown is made a very important central point for supplies of iron ores and anthracite. Several large blast furnaces, extensive iron works, and rolling mills are in operation. The population of Allentown are mostly of German descent, and the German language is still commonly spoken. It has 3 daily newspapers, 6 weekly, 1 semi-monthly, and 2 monthly periodicals. Allentown contains an academy, a military institute, and a theological seminary. Muhlenberg college, a Lutheran institution, was established here in 1867; in 1868 it had 10 instructors, 161 students, and a library of 1,800 volumes.

ALLESTREE, or **Allestrey, Richard**, an English divine, born in Uppington, Shropshire, in March, 1619, died in January, 1681. During the civil war he left his studies at Oxford to serve as a soldier in the king's army. Toward the conclusion of the war he took orders, and was one of those expelled when the parliament in 1648 sent visitors to Oxford to demand the submission of the university. He found an asylum in the family of Lord Newport in Shropshire, and after the battle of Worcester he was fixed upon by the royalists as a proper person to convey despatches and have a conference with the king at Rouen; and he was afterward the constant medium of communication with him. Soon after the return of Charles II. he was made canon of Christ's church, king's chaplain, regius professor of divinity, and in 1665 provost of Eton. Forty of his sermons were published in 1684, with a life by Bishop Fell.

ALLEYN, Edward, an English actor, born in London, Sept. 1, 1566, died at Dulwich college, of which institution he was the founder, Nov. 25, 1626. He was the friend of Jonson and Shakespeare, and partner of Henslowe as a theatrical manager and proprietor of the bear gardens. Having become rich, he purchased the manor of Dulwich in 1606, built his college there, and entered the institution with his wife, contenting himself with the same allowance of food and clothing as each of his pensioners. At his death he left property for the endowment of 20 almshouses, besides legacies to his wife and relatives. (See **DULWICH**.)

ALL-FOURS, a game played by two or four persons with an entire pack of cards. It derives its name from the four chances therein, for each of which a point is scored; these are: high, the best trump out; low, the lowest trump out; jack, the knave of trumps; and the game, the majority of pips reckoned for certain cards held by the respective players, every ace being counted 4, king 3, queen 2, knave 1, and ten 10.

ALLGAIER, Johann, a German chess player and writer on the game, died at Prague in 1826. For some years he was a captain in the Austrian service. He spent most of his life in Vienna. His work *Anweisung zum Schachspiel*, was first published at Vienna in 1795, and has since passed through numerous editions. A peculiar method of opening the game received from him the name of the Allgaier gambit.

ALL HALLOWS. See **ALL SAINTS' DAY**.

ALLIBONE, Samuel Austin, LL. D., an American author and bibliographer, born in Philadelphia, April 17, 1816. After some years spent in collecting materials for the purpose, he began in 1853 the composition of "A Critical Dictionary of English Literature and British and American Authors, Living and Deceased, from the Earliest Accounts to the latter half of the Nineteenth Century." This work, in 3 vols. royal 8vo (1858, 1870, and 1871), contains notices of 46,499 authors and 40 classified indexes of subjects. Dr. Allibone is also the author of

some religious controversial essays, and has contributed articles to the "North American Review," the "Evangelical Quarterly Review," and other periodicals; and he has privately printed and circulated a number of tracts.

ALLIER, a central department of France, part of the old province of Bourbonnais, bounded by Nièvre, Saône-et-Loire, Puy-de-dôme, Creuse, and Cher; area, 2,822 sq. m.; pop. in 1872, 390,812. It takes its name from the river Allier, which flows through its centre; the Cher, like the Allier a southern affluent of the Loire, flows through the western part of the department, and the Loire waters its eastern border. The surface is undulating, and the soil generally fertile, yielding much grain and wine. Coal and minerals of various kinds abound; and there are celebrated mineral springs. The department is divided into the arrondissements of Moulins, La Palisse, Gannat, and Montluçon. Capital, Moulins.

ALLIGATOR (Fr. *alligator*, It. *alligatore*, corrupted from the Sp. *el lagarto*, the lizard), a large carnivorous, amphibious reptile, of the saurian family, peculiar to America. The name was first given to this animal by the English colonists of the southern

Alligator.

portion of what are now the United States, but has been gradually extended to all the varieties of the family, called caymans, crocodiles, jacarés, &c., by the Spaniards, Portuguese, and Indians of the southern continent. The alligator was formerly believed to be identical with the crocodile of the old world; but there have subsequently been found to exist distinctions which indicate generic differences. The generic characteristics of the family are long flat heads, thick necks and bodies, protected by regular transverse rows of long plates or shields, elevated in the centre into keel-shaped ridges, and disposed on the back of the neck into groups of different forms and numbers, according to the species. The mouth is extremely large, extending considerably behind the eyes, and furnished in each jaw with a single row of conical teeth, all of different sizes, and standing far apart from one another. The eyes are placed on the upper surface of the skull, very near to each other, and provided with three eyelids. The feet have five toes before, long and separate; four behind, more

or less perfectly connected by membranes; the interior toes only, on all the feet, being provided with claws. The tail is of great length, slender, strongly compressed at the sides, and surmounted toward its origin by a double series of keel-shaped plates, forming two upright denticulated crests, which, gradually converging toward the middle of the tail, there unite and form a single row to the extremity. The tail is the animal's great instrument of progression in the water, and its great weapon of defence when surprised on land. Both genera, alligators and crocodiles, hibernate, taking no food during the winter months; the Nilotic crocodiles, according to Pliny, withdrawing into caves and holes in the banks, while the alligators of America bury themselves in the mud of stagnant rivers. The principal food of both alligators and crocodiles is fish, but they watch for and devour land animals and even men. It is alleged that the musky fluid secreted from the glands of the throat acts as a sort of bait, and attracts the fish on which they prey. The alligators, according to Cuvier, have the head less oblong than the crocodiles. Its length is to its breadth, measured at the articulation of the jaws, as three to two; the teeth are unequal in length and size; there are at least 19, sometimes even as many as 22, on each side in the lower, and 19 or 20 in the upper jaw. The front teeth of the under jaw pierce through the upper at a certain age; and the fourth from the front, which are the largest of all, enter into corresponding holes of the upper jaw, in which they are concealed when the mouth is closed. The hind legs and feet are round, and neither fringed nor pectinated on the sides; the toes are not completely webbed, the connecting membrane only extending to their middle; and finally, the post-orbital holes of the cranium, so conspicuous in the crocodiles, are very minute in the alligators, or even entirely wanting. Further than this, it is observable that the alligators, unlike the crocodiles, are rarely if ever to be found in running streams, preferring stagnant ponds and the creeks of large rivers, in which, particularly in South America, they may be seen in great numbers, protruding their large flat heads through the leaves of the nymphæa, pontederia, and other aquatic plants, and watching for their prey; or sometimes basking in the sun, or sleeping on the banks. They rarely come on shore, except during the hottest part of the day, and always retire to the water on the approach of night, during which they are extremely active in search of their food. They generally lay from 50 to 60 eggs in one place, of about the same size as those of the goose, which they cover up with sand, and leave to be hatched by the heat of the sun, never, however, removing to any great distance. When the young ones come forth, they are five or six inches long, and are immediately conducted to the water by the female alligator. Seldom more than half the brood long survive, the re-

mainder being devoured by the male alligators, and by various ravenous fishes; while multitudes are destroyed in the egg by the vultures. The alligators never leave the fresh water, while the crocodiles frequent the mouths of the large rivers, and swim out into the open sea, passing between different islands at considerable distances. So perfect a characteristic is this of the two genera, that the animal of the West India islands, which swims out into the salt water, is distinctly a crocodile, varying from all the other American species, and exhibiting the modifications which belong only by right to those of the old world.—The principal species are: 1. The alligator, properly so called, *crocodilus lucius* of Cuvier, *alligator Mississippiensis* of Gray, inhabiting the waters of the southern states. It grows to the size of 14 or 15 feet; its head is one seventh of the entire length, and half as broad at the articulation of the jaws as it is long. It has these distinguishing modifications from the crocodiles: The snout is flattened on its upper surface, and slightly turned upward at the extremity; its sides are nearly parallel, and the nose forms a regular parabolic curve. It is from this similarity to the head of a pike that it has its name *lucius*. It is said to be far more fierce and voracious than the South American species, often seizing and destroying men and large land animals, the bodies of which it conceals under the banks until they begin to putrefy, when it draws them ashore and devours them; for its teeth, unfitted for mastication, cannot cut the flesh in its sound state. The female of this species is remarkable for her maternal attention to her young, never losing sight of her nest until the little alligators are released from the shell. Bartram, the American naturalist, found great numbers of these reptiles in a mineral spring near the Mosquito river, Florida, though the water at its exit from the earth was nearly at the boiling point, and strongly impregnated with copper and vitriol. 2. The cayman, *alligator pulpebrosus*. This species is distinguished by its bony eyebrows, which form knobs as large as the fists of a man. Its toes are almost entirely free from connecting membranes, and its skull has no post-orbital apertures. It is smaller and less fierce than the others of its genus; and the female takes no heed to her eggs when they are once deposited. This is the alligator of Guiana and Surinam. 3. The alligator of Brazil, *alligator trigonatus*, a variety of the above species, distinguishable from it by a long ridge between the orbits running toward the snout, a notch in the posterior margin of the skull, and a peculiar arrangement of the cervical plates. 4. The jacaré, *alligator sclerops*. This is the alligator of all tropical America, particularly numerous in Brazil. Its head is more elongated than that of the North American alligator, the sides converging toward the snout so as to form nearly an isosceles triangle. The bones of the skull have a rough scabrous appearance, as if

diseased; and the orbits of the eye are surrounded by prominent rims of bone, connected by a ridge between the orbits, constituting together the resemblance of a pair of spectacles, whence its name. It grows to a very large size, attaining even to 18 feet, its length being more than eight times that of the head. It never attacks men, or even dogs, whether on land or in passing rivers, unless in the neighborhood of its nest; nor does it then prey on the carcasses, feeding only on fish and water fowl.—The bony armor of all the species is their protection against all enemies. It is proof against the rifle ball, which can only take effect when it strikes the eye, or the unarmed skin on the belly and about the insertion of the fore legs. The construction of this armor, however, prevents them from turning rapidly when on dry land, so that their pursuit is easily avoided. Their flesh, and even their eggs, although both have a strong musky flavor, are said to be both wholesome and nutritious. The American alligators have neither their allied protector bird, the spur-winged dotterel, nor their characteristic enemy, the ichneumon, which protect or assail the crocodile of the Nile. The hideous aspect, disgusting habits, abominable smell, and odious roar of these reptiles have rendered them objects of undue apprehension. (See CROCODILE.)

ALLINGHAM, William, a British poet, born at Ballyshannon in Ireland about 1828. His father, a banker in his native town, gave him a good education in Irish schools; and he early showed a taste for literary pursuits, contributing to various periodicals. In 1850 he published a volume of poems, which he dedicated to Leigh Hunt, who had long appreciated and encouraged his work. In 1854 he published "Day and Night Songs," of which an enlarged edition, illustrated by artists of note, appeared the next year. In 1864 he published a poem in twelve chapters, entitled "Laurence Bloomfield in Ireland;" but it is by his short lyrics that he is best known. He has for some years held a government appointment in the English customs service, and he has also been since 1864 in receipt of a literary pension. He has edited "The Ballad Book."

ALLIX, Pierre, a French Protestant divine, born in Alençon in 1631, died in London, March 3, 1717. While pastor of a reformed congregation at Charenton he assisted Claude in preparing a new French version of the Bible, and acquired some celebrity by a controversy with Bossuet. On the revocation of the edict of Nantes he took refuge in England, established a French congregation in conformity with the Anglican church, and in 1690 was appointed by Bishop Burnet treasurer of Salisbury cathedral. He made several attempts in Holland, Switzerland, and Germany, to cement a more perfect union among the reformed churches. Besides a number of theological and critical works in French and Latin, he wrote in English (of which he was an excellent

master) "Reflections upon the Books of Holy Scripture" (1688); "Remarks on the Churches of Piedmont" (1690); "Remarks on the Ancient Churches of the Albigenes" (1692), &c.

ALLOA, a seaport town of Clackmannanshire, Scotland, 30 m. E. N. E. of Edinburgh, at the head of the frith of Forth; pop. about 7,000. It has an excellent harbor, and a dry dock capable of containing the largest ships; also a spacious wet dock opened in 1863. In the town and its vicinity are extensive collieries, distilleries, breweries, and iron, glass, brick, and tile works.

ALLOBROGES, a people of Gaul, whose territory comprehended parts of what is now called Dauphiny and Savoy, chiefly between the Isère and the Rhône. Their principal town was Vienna, now Vienne, on the left bank of the Rhône. They were brought under the dominion of Rome in 121 B. C., by Fabius Maximus, and ever after remained faithful to their conquerors, though at times discontented. Their name signified "dwellers on mountains."

ALLODIUM, in law, a landed possession freed from all feudal tenure or service. Several explanations have been given of the etymology of the word, but they are all only more or less ingenious conjectures. In early ages the allodium was the most desirable property. In process of time the anarchy consequent on the want of a supreme power made the mutual protection and support of lord and vassal more expedient; and in England all land passed into fee land, the king being suzerain of the whole country. The theory still remains in slight services, or in small fee farm rents, and in the escheat to the sovereign for want of heirs. In France, before the revolution of 1789, the actual services still remained—not nominal, but real, unequivocal, and in some cases odious burdens; serfdom, indeed, was only abolished by an express decree of the assembly. *Nulle terre sans seigneur* was a maxim of law, and the tyranny and monstrous oppressions of the local seigneur proved that it was no dead letter. In Germany the allodium yet remains to be perfected. The system of man service is not yet exploded, such as the right to several days' work in harvest or at hunting parties; although this is much modified, particularly in Prussia, of late years. The conversion of the feudal soil into allodial land is effected either by means of an annual fee rent, or of a fine payable at once, in lieu of all customary services. Even in 1595 the last traces of bondage and serfdom in England were not obliterated. A patent to Sir Henry Lea was issued by the crown, giving him power as commissioner to enfranchise a limited number of crown villeins, and to seize all the rest of the estates acquired by parties in villenage to his own use. This monstrous commission, which was, like many other similar enormities, a means of enriching a needy or profligate courtier at the expense of the people, could not have operated except in the case of crown serfs; the doctrine,

Nullum tempus occurrit regi, coming into operation against the unfortunate landholders whose title was barred by the impurity of their blood. In the case of subjects, villenage had become obsolete.

ALLOM, Thomas, an English architect and landscape painter, born in 1804. His reputation rests chiefly on his published works illustrating the scenery, architecture, and antiquities of England, France, and the East.

ALLOMAKEE. See ALLAMAKEE.

ALLOPATHY, a word created by homœopaths to distinguish other systems of medical practice from their own. Having adopted the opinion that "like cures like" (*similia similibus curantur*) as the fundamental principle of his doctrine, Hahnemann gave to his own system the name of "homœopathy," derived from the Greek ὅμοιον, like, or similar, and πάθος, disease, and from other systems the name of "allopathy," from ἄλλοιον, other, or different, and πάθος, disease.

ALLORI. **I. Alessandro**, a Florentine painter, born in 1535, died in 1607. He was a nephew and pupil of Agnolo Bronzino, whose name is sometimes given to him. Michel Angelo was his chief model, and he is reputed one of the best artists of the anatomical school. He excelled also as a portrait painter. **II. Cristofano**, also called Bronzino, son of the preceding, born in 1577, died in 1621. He painted several important works for the Florentine churches and convents and the palace of the Medici, and excelled in coloring and delicacy of execution. His best known work is "Judith with the Head of Holofernes," in the Pitti palace, but his St. Julian in the same gallery is esteemed superior to it. His works are very rare.

ALLOTROPISM (Gr. ἀλλότροπος, in another manner), a word first employed by Berzelius to denote the property in virtue of which the same element can have different chemical characters. There exists a vast series of phenomena, of which polymorphism constitutes the first term, allotropism the intermediate, and isomerism the extreme term. Sulphur, which crystallizes from its solution in octahedra of the fourth system, when crystallized by means of fusion forms prisms having a rhombic base, of the fifth system; this is a polymorphous body. Phosphorus being heated changes its properties; if we heat it still further, it regains its original condition. It can therefore exist in two different states, but it is always phosphorus. This is a phenomenon of allotropism. The formiate of ethyl, C₂H₅O₂, and the acetate of methyl, C₂H₅O₂, are two perfectly distinct bodies, although they have the same quantitative composition; they are isomeric. To take an illustration from natural history, allotropism only makes races, isomerism creates distinct species. Isomeric bodies receive distinct names; but sulphur, phosphorus, oxygen, carbon, &c., in their modified forms, that is, in their allotropic conditions, are still sulphur, phosphorus, and oxygen. Originally the word

allotropism was only applied to elements; later it was also applied to compounds. Tartaric acid which turns the plane of polarization of light to the right, tartaric acid which turns it to the left, and that which does not deviate it at all, are considered by some chemists to be the same compound in several allotropic states. (See ISOMERISM.)

ALLOUEZ, Claude Jean, one of the earliest Jesuit explorers of the northwest, born in France in 1620, died in 1690. He went to Quebec in 1658, and, after some years' training in the Algonquin missions on the St. Lawrence, founded the mission of the Holy Ghost at Chegomegon on Lake Superior in 1665, collected data as to the Mississippi, explored Green bay, where he founded the mission of St. Francis Xavier, and labored among the Foxes, Mascoutins, Miamis, and Illinois. In 1676 he permanently established at Kaskaskia in Illinois the mission begun by Marquette; but in 1679 he retired on the approach of La Salle, who was bitterly opposed to the Jesuits. His latest field of labor was among the Miamis on St. Joseph's river, where he died. His contributions to the Jesuit *Rélativités* are among the most valuable records as to the ideas and manners of the Indians at the time.

ALLOY (Fr. *aloi*, standard of coin, from *à la loi*, according to law), a compound of two or more metals fused together. When one of the metals is mercury, the compound is called an amalgam. (See AMALGAM.) By the alchemists metals were called "noble" and "base," and when one of the latter was brought into combination with one of the former, the nobility of this was said to be "alloyed" or "alloyed," and assayers at the present day still use the term in this sense. Most alloys are mixtures of no exact proportions; the metals dissolve in one another indefinitely, as sulphuric acid unites with water. Some, however, appear to be combinations in equivalent proportions, and of these there are found examples in nature, as of the native gold, which occurs combined with silver—4, 5, 6, or 12 atoms of gold to one of silver, but never a fractional part of an atom of gold. The tendency of some alloys to take crystalline forms also indicates definite combinations. This is verified by cooling a melted mixture slowly, and when partially solidified pouring off the liquid remnant, when crystals are left which are always combinations in the proportion of the atomic weights of the metals; for instance, in the mixtures of copper and tin (bronze), copper and zinc (brass), copper and nickel (German silver), or copper and aluminum (aluminum bronze), the proportions of the crystals are found to be either in the ratio of the numbers 64, 118, 65, 59, 27, which are the respective atomic weights of copper, tin, zinc, nickel, and aluminum, or of a multiple the one of the other. The metals of many alloys are with difficulty brought into combination, and even tend to separate from each other while in the melted state, and in

some instances form layers which contain different proportions of the metals.—The changes in the physical properties of metals effected by their combinations are of great variety, and cannot before experiment be at all anticipated. Even slight variations in the proportions of the metals involve great changes in the product of their union. The specific gravity of the alloy may be greater or less than the mean of that of the component parts. In the alloy of gold and tin it is greater; also of silver with zinc, lead, tin, bismuth, or antimony; copper with zinc; lead with palladium; bismuth with antimony; lead with bismuth; and zinc with antimony. The specific gravity is less in the alloy of gold with silver, lead, iron, copper, nickel, or iridium; also of iron with bismuth, zinc, antimony, or lead; tin with lead; zinc with palladium or antimony; and zinc with antimony. The alloy of silver and copper as used in coins is also of less specific gravity when cast; but Karmarsch found that by rolling and coining it is so far compressed that the specific gravity is the same as the mean obtained by calculation. Alloys are always more fusible than the metal most difficult to melt that enters into their combination, and generally more so than the most easily melted one. The fusible metal discovered by Sir Isaac Newton melts at different temperatures between 198° and 210° F. It is composed of bismuth 5 or 8 parts, lead 2 or 5 parts, and tin 3 parts. These metals melt, the first at a temperature of 476°, the second at about 600°, and the last at 442°. The addition of one part of mercury lowers the melting point of this alloy to 167°. Wood's fusible alloy, discovered in more recent times, consists of 2 parts cadmium, 2 tin, 1 lead, and 3 bismuth; it melts at the low temperature of 150° F. The alloy fusible at the lowest temperature is that of sodium and potassium; the first melts at 194°, the second at 128°, while the alloy melts at 80°, and is thus liquid at the common summer temperature. Alloys conduct heat and electricity less perfectly than their pure metals; they are also generally more brittle. But their power of cohesion is usually greater than that of either of the metals, the alloy resisting more strongly the force applied to draw a bar apart than does a bar of either one of the metals composing it. The color which the alloy will take is as uncertain as any of its other properties. A large addition of zinc will not make its alloy with copper whiter, but will give it the rich pinch-beek hue. Tin makes copper more pale, but especially nickel, the addition of one eighth of which is sufficient to make it almost white. Aluminum acts in a similar way, while silver possesses the power of destroying the red color of the copper in so high a degree, that it may be largely alloyed with it without materially impairing its whiteness. Alloys composed of metals of different degrees of fusibility may sometimes be separated into their distinct metals by heating to the melt-

ing temperature of one of them. An alloy of tin and copper may be thus treated, the tin melting at 442° , and the copper at $1,996^{\circ}$. This "sweating process," called liquation, is used to separate silver from copper. Lead is first melted in with the other metals, and when sweated out it takes the silver along with it. This alloy is then separated by another process, depending on the easy oxidation of the lead. An interesting property of the metals, which may seem somewhat opposed to the one just described, is the tendency of one, when melting, however fusible it may be, to cause any other in contact with it, however infusible, to dissolve in the melted metal; its surfaces are washed away, till nothing solid is left. Platinum, which is among the most difficult metals to melt, is very susceptible of injury from this cause. The costly crucible and other vessels of the chemist may be ruined in an unguarded moment by contact with other metals highly heated. On this property is based the principle of soldering two pieces of metal by means of a third. Their surfaces are fixed together by interposing an alloy which is more fusible than either of the metals to be joined; and this must also consist of metals which are disposed to unite and form a new alloy with them. Pieces of gold are soldered together with an alloy of gold with silver or with copper; articles of silver with an alloy of silver and copper; of copper, with an alloy called hard solder, which is brass containing a large proportion of zinc. Another interesting property of alloys is the different effects produced by the order in which their component parts have been mixed, the proportions continuing the same. Ten parts of antimony added to 90 of tin and 10 of copper, make a compound of very different physical properties from that produced by adding 90 parts of tin to 10 of copper and 10 of antimony. This appears to be analogous to what we witness in vegetable chemistry, as in the identity of composition in starch and sugar.—The alloys already in use are very numerous, and new valuable combinations are continually discovered. Those alone of copper with zinc form a long list, in which we find the names of many very useful compounds, some of them known from the time of Tubal Cain. Pewter has long been a useful, though a very homely alloy. It is made of different combinations of lead and tin, sometimes with additions of antimony, bismuth, and copper, and in this case is known in trade under different fanciful names, as britannia, &c. German silver, composed of copper, nickel, and usually zinc, has in part displaced it, and is likely to be itself displaced by some improved combinations. Muntz's yellow metal is an alloy of 60 parts of copper to 40 of zinc. These proportions may be slightly varied, but they are the ones specially recommended in the patent, as producing a composition more easily rolled into sheets while hot. It is used for sheathing the bottoms of ships. In importance, no alloys

can rank higher than those of which printers' types are made, and no known metal possesses the properties essential to them. They consist of lead and antimony, in proportions varying with the kind of types. For very fine types tin is added, to increase the fusibility and consequently to make the metal flow better, so as to fill the finest details of the mould. Many type founders introduce also some copper, by first alloying it with the antimony; this increases the durability of the type considerably. The noble metals, gold and silver, are too soft to be used in a pure state. They are alloyed with copper to give them hardness, and gold also with silver. The standard silver of Great Britain consists of silver 11-10, and copper 0-90. The French silver plate contains 9-5 parts of silver and 0-5 copper; trinkets, 8 parts of silver to 2 of copper. In the United States these alloys are made as rich or as poor as the individual manufacturer judges best for his interest. His reputation is the only guarantee that his work is what it is sold for. There is no test but actual analysis, and this is not applicable to the articles without destroying part of them. Specific gravity may be employed to some extent, but as the alloy often has a somewhat different density from that of the mean of its metals, the calculation gives an approximation more or less correct according to circumstances. The following rule given by Dr. Van der Weyde may be used to find the specific gravity of an alloy made of any number of metals, mixed in whatever proportion: "Find the relative volume of each metal by dividing its weight by its specific gravity; the sum of all the weights divided by the sum of the volumes gives the specific gravity of the alloy."—An alloy which closely resembles gold in color, specific gravity, and ductility, is made of 16 parts of platinum, 7 parts of copper, and 1 of zinc. These are put into a crucible, covered with charcoal powder, and melted. Its cost is scarcely one fourth of that of gold. The so-called oroid gold is a very base alloy, only resembling gold in color if kept clean, and is easily distinguished from it by having scarcely half its specific gravity. It is said to be made by melting copper 160 parts, tin 17, magnesia 6, carbonate of potash 9 or salt of antimony 3-6, and quicklime 1-6. The latest improvement is the so-called sterrometal, invented by Rosthorn in Vienna; it is made by melting 600 lbs. copper with 2 lbs. cast iron; when fluid there is added 36 lbs. zinc and 4 oz. borax. It is asserted that it is 8,000 lbs. stronger per square inch than the best wrought iron. Alexander Birchholz of Hartford, Conn., has patented the same alloy, and erected a factory in Providence, R. I.—Among interesting applications of alloys we must mention the plates of easily fusible metals with which steam boilers are sometimes provided, offering an additional safety besides the safety valve, as they will melt at a temperature corresponding with too high a pressure. Another application

is founded on the fact that alloys are much more imperfect conductors of electricity than the separate metals, from offering more resistance. Small coils of wire are made of an alloy similar to German silver, in which the resistance is equal to many miles of telegraph wire; they are used in connection with voltmeters to measure the strength of batteries, and to detect imperfections or breaks in telegraph wires.

ALL SAINTS' BAY, or *Bahia de Todos Santos*, in the province of Bahia, Brazil, one of the largest and finest natural harbors in the world. It is 37 m. long and 27 wide, and its surface is dotted with islands. The town of Bahia lies on the E. side of the bay.

ALL SAINTS' DAY, a festival in honor of all the angels and saints of heaven, observed in the Roman Catholic church on Nov. 1, and also in the Protestant Episcopal and Lutheran churches. In the eastern churches the same festival has been observed since the 4th century. In the West, it was instituted by Pope Boniface IV. in the early part of the 7th century, on the occasion of dedicating the Pantheon, a temple built by Marcus Agrippa, 25 B. C., in honor of Jupiter the Avenger and all the gods, to the worship of the true God, under the invocation of the Virgin Mary and all the saints. The feast became general in the 9th century. It is also called All Hallows.

ALL SOULS, the day after All Saints, set apart by the Catholic church for the commemoration of all the faithful departed, for whom the mass of requiem is said, and the office of the dead recited. In Germany, the people, both Catholic and Protestant, visit the graveyards on this day, and strew flowers on the graves of their friends.

ALLSPICE, or *Jamaica Pepper*, the immature berry of the *Eugenia pimenta*, so named from

its being supposed to combine the flavor of several other spices, such as cinnamon, cloves, and nutmeg. The allspice, pimento, or bayberry tree is a native of South America and the

West India islands, especially Jamaica. The tree is of a highly ornamental character, often upward of 25 or 30 feet in height; the leaves inclining to oval, covering the numerous branches with a luxuriant evergreen foliage; the flowers small and without show, succeeded by spherical berries with a persistent calyx, and a fragrant aromatic odor. When they are quite ripe, they are of a dark purple color, and filled with a sweet pulp. In many parts of Jamaica the allspice tree grows in great abundance without cultivation, but it is not easily propagated by artificial means. The commercial value of the fruit makes it an object of great interest with the planters, and no crop receives a larger share of attention. The favorite situation for a pimento walk, or plantation, is among the hills on the north side of the island. A spot is selected in the vicinity of another plantation, or in a locality favorable to the spontaneous growth of the trees; this is stripped of all other wood, and the young pimento plants soon make their appearance, either from seeds previously existing in the soil, or which have been deposited by birds, who feed upon the berries with great avidity. It is said that a single tree has been known to produce 150 lbs. of the raw fruit, or 100 lbs. of the dried spice. The crop, however, is uncertain, and abundant only once in five years. The berries require care in gathering as well as drying. They must be picked when they have attained full growth, but before they begin to ripen, and carefully dried. When the seeds are allowed to ripen fully, they lose that aromatic warmth for which they are esteemed as a spice, and acquire a taste almost exactly like that of juniper berries, which renders them agreeable food for birds, the most industrious planters of these trees. The leaves and the bark participate in the warm aromatic properties of the berries.

ALLSTON, Washington, an American painter, born at Waccamaw, S. C., Nov. 5, 1779, died in Cambridge, Mass., July 9, 1843. From considerations of health he was removed in his early boyhood to Newport, R. I., and completed his education at Harvard college, where he graduated in 1800. Having developed a decided inclination for painting, he went in 1801 to London and became a student of the royal academy, then under the presidency of his countryman Benjamin West, to whom he was indebted for many useful hints in the prosecution of his art. A three years' course of study in London was succeeded by a lengthened sojourn in Rome, where he familiarized himself with the works of the old masters, and gained a reputation as a colorist. During a brief visit to America in 1809 he married a sister of Dr. William Ellery Channing, and returning soon after to London entered upon his career as an artist. Within the next few years he produced a number of works of great merit, founded for the most part on subjects taken from sacred history. Two of these, "The Dead Man Re-

vived by touching the Bones of Elijah," and "Uriel in the Sun," displaying high imaginative power and a rare mastery of color and chiaroscuro, obtained for the artist valuable prizes from the British institution, and all of them found ready purchasers. He returned to America in feeble health in 1818, and during the remainder of his life resided principally in Boston and Cambridge. His subsequent career was without the incentive to exertion which he had experienced in England. His countrymen respected him for the reputation he had acquired abroad, but were scarcely able to appreciate his talents. Removed from the congenial atmosphere of the great art capitals of the old world, he worked listlessly and irregularly, and produced no finished performance of importance comparable in merit with his earlier pictures. During the last 25 years of his life he occupied himself from time to time on a composition of great size representing "Belshazzar's Feast," which he intended should be his masterpiece. But frequent attacks of illness, an over-fastidiousness of taste, and an ideal which became more exalted and exacting as he advanced in years, seriously marred the progress of the work, and it remained at the close of his life an unfinished but splendid specimen of his genius. It is now the property of the Boston Athenæum. Allston's works are not numerous, considering the extent of his career, but bear the imprint of an original and artistic mind. The best are founded on Scriptural subjects. He also painted landscapes and sea pieces of great excellence, and in ideal portraits combined an almost unrivalled purity of flesh tints with depth and power of expression. Had he possessed the moral courage and the physical ability to embody on the canvas his own conceptions, he would have proved one of the most prolific and imaginative artists of the age. No American painter has yet approached him in the delineation of sacred history. Allston was a man of fine literary tastes, and conversed with ease and eloquence on art and metaphysics. He published a volume of poems and a novel, "Mondaldi," illustrating Italian life.

ALLUVIUM (Lat., from *alluere*, to wash upon or against), the deposits of sand, gravel, marl, &c., brought down by running streams of the present geological period. Other recent accumulations also, as those of peat and of the hills of sand blown together by the wind, are often called alluvial. They all belong to Lyell's uppermost group, the post-tertiary, and are characterized by containing human relics and remains. The same group comprises the calcareous rocks of recent origin which occur on the coast of Guadeloupe, and contain human skeletons imbedded in solid limestone, and also the coral reefs which are in process of formation in tropical seas, spreading out in calcareous strata hundreds of miles in extent. These are not usually included in the term-alluvium; and yet it is not easy to draw a line

that shall exclude any formations of recent origin; for the wash of rivers, as it settles in the bays at their mouths, often finds some cementing matter that soon binds it into solid rock, and in this hard rock are entombed as fossils works of art or remains of man. Thus the term alluvium has no precise signification. The great deposits of alluvium accumulate so slowly and silently, that we little appreciate the immense changes made by running water upon the surface of the earth; yet in the short period from the time to which our records extend back, we find that the sediments of a few small Italian rivers have carried out the coast line into the gulf of Venice from 2 to 20 miles; and that the ancient port of Adria, which in the time of Augustus gave its name to the gulf, is now an inland town, 15 miles from the shore. According to Herodotus, the ancient priests of Egypt regarded their country as "the gift of the Nile." From the great pyramids down to the sea all is made land. The great rivers of the world, as the Mississippi, Amazon, Ganges, and Orinoco, are producing effects far greater than those of the Nile; but our observations of these extend but a few generations back, and we lack sufficient data for calculating very exactly the rate of increase of their deltas. With the Mississippi, however, this has been attempted by Mr. Forshey, an eminent engineer, from observations extending through 30 years. Adopting the estimate of Dr. Riddell of New Orleans, that the weight of sediment is $\frac{1}{1215}$ of that of the water, or $\frac{1}{3000}$ of its volume, and allowing the quantity of water brought down per second to be 447,199 cubic feet, the whole amount of sedimentary matter annually added to the delta and carried into the gulf is equal to 4,083,333,333 cubic feet, enough to cover 144 square miles one foot deep. And yet at this rate, for the river to have built up the great accumulations of alluvium which make its delta, would have required 61,000 years; and higher up there are the accumulations at this rate of some 30,000 years more. Thus long at least, it is probable, the great rivers have flowed as they now flow; and during this latest epoch few changes have occurred in the lower forms of animal life; for in the strata next older than these alluvial deposits, the land and river shells are all of the same species with those now living in the same region. Subsequent investigations by Capt. Humphreys and Lieut. Abbot (1858) have given results which will be described under MISSISSIPPI RIVER.—The delta of the Ganges and Bramapootra is far more extensive than that of the Mississippi. It is a wilderness filled with a labyrinth of rivers and creeks, infested with tigers and crocodiles, and larger than the principality of Wales. The rivers pour down their turbid waters charged with sediment, and abounding with the ruins of animal and vegetable life. These are swept into the bay of Bengal, the waters of which are discolored by the fine mud nearly 100 miles from its mouth, while the heavier materials

subside near the shores and build up the alluvial strata. Near Calcutta, it was ascertained on boring for water that these strata continue below the surface to the depth reached, which was 481 feet. They were alternations of beds of clay and of marl, with others of decayed vegetable matter like peat, which last no doubt had at times formed the surface, until submerged by subsidence, and then buried beneath the deposits of the rivers. In these strata various fragments of fossil bones and shells were brought up, all of which indicated the existence of the same animals that now inhabit the region.—What the rivers are accomplishing in the interior, the tidal currents are effecting along the coasts. They wear down what has been built up in former times, and strew the materials in new deposits of alluvium. In Germany these accessions, called *Anlandung*, are of great value along the coast of the North sea. On the American coasts they are more commonly of a sandy character, stretching out in long beaches, the material of which is blown inland by the winds and piled into barren hills. The long sandy strip of land called the Great South Beach on the S. side of Long Island, which is a remarkable example of these sandy strips or “spits,” is more than 100 miles in length, exceeding any such accumulation in Europe. These sands are now formed into alluvial beds by the action of the winds and of the ocean currents; but there is good reason to believe that the greater proportion of the superficial covering of the rocks of Long Island is nothing more than the accumulations of sediment discharged by the Hudson, Hackensack, Passaic, and Raritan rivers.—Alluvial deposits are frequently found in positions above the level of present running waters. Thus, around the shores of some of our great lakes are occasionally seen in the banks layers of sand and clay containing the same species of shells that are now common in their waters, but several feet above their reach. It was during this modern period of the formation of the alluvium that the gigantic mammoths and mastodons became extinct. Their bones are found in the peat bogs and marl beds, the origin of which probably does not extend far back from the introduction of man. Indeed, if we may place confidence in the traditions of the American aborigines, we must believe that these animals were contemporary with man. Within the ribs of a mastodon found in Warren county, N. J., in 1845, were seven bushels of vegetable matter. In the western states the bones of these animals are generally discovered in the low places around salt licks which are still frequented by the deer and other wild animals that come to suck up the saline waters.—If the alluvium is interesting for these gigantic fossils, it is no less so for the microscopic forms of vegetable and animal life, which, though invisible to the eye, yet by the immensity of their numbers exceed in aggregate bulk that of all the mastodons and mammoths that have ever

lived. The silicious deposit, resembling fine white marl, found underlying peat, and at the bottoms of ponds and marshes, especially in a region of primary rocks—a substance often used as a polishing powder—is found on examination by the microscope to consist of the remains of diatoms and desmids.—As these vegetables secrete from the primary rock its principal ingredient, so testaceous animals secrete from the limestone the calcareous matter for their shelly coverings; and of their remains are made up the marl beds and other beds of alluvium that abound in shells, as the oyster banks and muscle beds of our coast. The lime of which the latter is composed is no doubt mostly abstracted from that held in solution in sea water. But salt water, fresh water, and land shells all flourish best where limestone rocks abound; and where this source of lime is deficient, they even acquire the materials of their own shells from the remains of former individuals. The accumulations of this nature going on in our ponds, lakes, and harbors, though now little apparent to observation, are a part of the alluvial formation that will have an important bearing in the future economy of our globe, as the similar formations of previous epochs have in the present period. And the same remark may be extended to peat, beds of which are found rivalling, in the quantity of carbonaceous matter they contain, the beds of fossil fuel, into which they too will in time be converted.—The most interesting feature of the alluvium, which has been already incidentally alluded to, is its being the only geological formation which contains human relics and remains. In no other formations are they found, or ever will be; for the races of animals and plants that have lived at different periods have not failed to leave permanent records of their most delicate organizations, and in the rocks of a very different epoch are still to be seen the footmarks left by strange forms of birds. Thus man and his works characterize the rocks of this period, as the gigantic birds characterize the new red sandstone, and the great saurians the formations from the lias to the chalk.—The alluvial deposits produce our most fertile lands. The clays are the materials of our houses and household utensils. The sands are used for many purposes in the mechanical arts. Bog iron ores collect in low marshy places from the filtration of water through older formations, in which ferruginous matters of various forms are diffused. The water dissolves the oxide of iron and conveys it away, as it dissolves the potash from ashes through which it leaches. It gathers the scattered materials of the ore together, and as it evaporates leaves them in form suitable for use. As the ores are removed, more collect and renew the supply; so that they are believed by many, who do not comprehend the manner of their silent accumulation, to be endowed with a principle of growth analogous to that possessed by organic bodies: a belief which, after

all, may not in one sense be so very extravagant; but according to the researches of Ehrenberg, the ochreous particles, under the microscope, prove to be portions of an organic body of extreme minuteness, which is now believed to be a plant.

ALMA, a small river in the Crimea, running from the high ground in the neighborhood of Bakhchisarai in a westerly direction to Kalamita bay, between Eupatoria (or Kozlov) and Sebastopol. The southern bank of this river was selected during the Crimean war by Prince Mentelikhoff, the Russian commander, as a defensive position in which to receive the onset of the allied armies just landed in the peninsula. The battle was fought Sept. 20, 1854, and resulted in a victory of the allies and the opening of the road to Sebastopol. The Russian force numbered 35,000 men with 96 guns; the English, under Lord Raglan, 28,000 men with 24 guns; the French, under St. Arnaud, 28,000 men and 72 guns; and the Turks, 6,000 men.

ALMACK'S, a suite of assembly rooms situated at No. 26 King street, St. James's, London, so called after Almack, a tavern-keeper, whose original name was M'Call, and who founded the establishment in 1765. They are now called Willis's rooms after Frederick and Charles Willis. Here take place concerts, charity balls, and select public meetings. The annual balls, however, which are held during the season, constitute the chief claim to the prominence of Almack's. They are managed by a committee of ladies, and the only mode of admission is by vouchers or personal introduction. The exclusiveness of the lady patronesses, great as it is now, was incomparably greater at the time of the opening of the rooms. Down to about 1830 Almack's retained a great deal of its ancient prestige, but since that time it has been gradually declining.—The name of Almack's has been given to similar places of entertainment in European watering places. A gambling club of the same name, opened under the auspices of the same proprietor in Thatched House tavern, 85 St. James's street, was rather notorious toward the end of the 18th century, the play there having been deeper than either at White's or Brookes's. Before Brookes's club house was built, the whig party used to meet at Almack's, where a regular book was kept of the wagers laid by the different members. The following are specimens: "March 11, 1775. Lord Bolingbroke gives a guinea to Mr. Charles Fox, and is to receive 1,000 from him whenever the debt of this country amounts to £171,000,000 sterling. Mr. Fox is not to pay the £1,000 till he is one of his majesty's cabinet." "Aug. 7, 1792. Mr. Sheridan bets Lord Lauderdale and Lord Thanet 25 guineas each, that parliament will not consent to any more lotteries after the present one, to be drawn in February next."

ALMADEN, or **Almaden del Azogue** (the mine of quicksilver), a town of Spain, in the province of Ciudad Real, about 50 m. N. of Córdoba; pop. about 9,000. It is simply one

long street, built on a ridge of quartz rock, which is rich in cinnabar. The quicksilver mines here are perhaps the richest and most ancient in the world. They were wrought by the Romans, who had a town here called Sispona Cetobrix. In the 16th century the Fuggers of Augsburg rented the mines and worked them for some years. They were subsequently operated by the Spanish government, and until the early part of the present century the laborers were all convicts, but free persons are now employed. The product of the mines is delivered at Seville, and since 1836 has been by contract monopolized by the house of Rothschild. The principal mine is directly under the town, and the great adit is close to the houses, the ascent and descent for the men being by ladders, while the mineral is drawn up a stone shaft by mules. The depth of the workings is about 1,000 feet, and the cinnabar is found in three principal veins several feet thick. The lowest portions of the mine are the richest. Virgin quicksilver is found in pyrites and hornstein and in a grayish conglomerate, and in some places may be seen running down the face of the rock. The galleries and permanent works are all splendidly built of stone, and there are extensive storerooms and manufactories of everything needed for carrying on the operations of the mine. The annual yield of quicksilver is from 15,000 to 25,000 quintals, though the proportion of mercury to the ore is only about 10 per cent.; and the mines are apparently inexhaustible. There is a smaller mine near the principal one, and another, called Almadenejos, or Little Almaden, about five miles distant. The number of hands employed is about 4,000. They work day and night during the winter, and in summer the mines are closed, the heat then rendering the mercurial exhalations too dangerous. The miners suffer a great deal from salivation and paralytic affections, but the summer's rest generally restores their health. The government derives an annual profit of about \$1,250,000 from the mines. A practical mining school has been established in the town.

ALMAGEST (Arab. *al the*, and Gr. *μεγίστη*, greatest), a name given by the Arabians to Ptolemy's compend (*σύνταξις*) of astronomy, written at Alexandria in the 2d century, translated from Greek into Arabic in the 9th, and translated from Arabic into Latin in the 13th. A better Latin translation from the original Greek was published at Basel in 1541. The Greek text with a French translation was published at Paris in 4 vols. (1813-'28).

ALMAGRO, a city of Spain, in the province and 12 m. E. S. E. of Ciudad Real; pop. about 11,000. It is celebrated for its laces, in the manufacture of which thousands of women are engaged in the town and its vicinity. Almagro was founded in 1214 by Archbishop Roderic of Toledo.

ALMAGRO, Diego de. I. One of the associates of Pizarro in the conquest of Peru, born of un-

known parents about 1464, and picked up as a foundling near the Spanish town from which he derived his name, died in 1538. He had acquired both wealth and fame in the new world, when he joined Pizarro at Panama in the attempt to conquer the flourishing kingdom of the Incas. In the division of offices among the leaders of the enterprise, Almagro was appointed to manage the forwarding of supplies of men and provisions, in which he had to contend with many formidable obstacles, but overcame them all. From the time of the first landing of the Spanish forces until the death of Atahualpa, Almagro was engaged in repeated quarrels with Pizarro, whom he accused of treachery in depriving him of his just share in the fruits of their conquests. He finally attempted to seize Cuzco, the capital, but was persuaded by Pizarro to undertake instead the reduction of Chili, of which kingdom he was to have the undivided control. In 1535 he set forth with 570 European followers, and underwent great hardships among the mountains. The natives resisted him bravely, but he had made some progress when a rising of the Peruvians, who had attacked Lima and Cuzco, summoned him home. Returning by a toilsome march along the coast, he defeated the natives, and took possession of Cuzco, which he resolved to hold. A civil war ensued, in which Almagro neglected to avail himself of his advantages until Pizarro, having gained time to recruit his forces by negotiation, marched to Cuzco with 500 men, and, defeating him in a bloody engagement, took him prisoner. After several months of confinement, he was tried, condemned, and strangled. He was a man of frank and winning manners, and far more popular among his men than Pizarro. He had never learned to read and write. II. The son of the preceding by a Peruvian woman, was a brave, generous, and accomplished youth; his father, mindful of his own deficiencies, having spared no pains in his education. He became the leader of the party opposed to Pizarro upon the death of the elder Almagro, and, after the assassination of the governor, was proclaimed his father's successor. He enjoyed authority for a very brief season, however, as Vaca de Castro soon arrived, bearing a royal commission as governor. Almagro attempted to resist him, and on Sept. 16, 1542, a sanguinary engagement took place between the forces of the rival leaders, in which the victory remained with his opponent. Almagro escaped after the battle, but was given up by his own officers, and beheaded at Cuzco.

ALMALI, or **Elmalu**, a city of Turkey, in Asia Minor, 40 m. W. S. W. of Adalia; pop. about 12,000. It lies in a beautiful valley among the northern offshoots of the Lycian range of the Taurus. The small stream on which the town is built furnishes motive power for numerous mills, and is also used in several tanneries, dye works, and factories.

AL-MAMOUN, **Abu Abbas Abdallah**, an Abbasside caliph, son of Haroun-al-Rashid, reigned from

813 to 833. After the death of his father in 809 he contested the throne with his brother Al-Amin, who was killed. He converted his chief towns into seats of learning. Various works were translated from Greek and Sanskrit. Algebra and arithmetic were borrowed from the Hindoos, astronomy from the natives of the plains of Mesopotamia, and logic, natural history, and the Aristotelian system from the Greeks of the lower empire. In his wars Al-Mamoun was less successful, and the disintegration of the caliphate by the establishment of independent states in parts remote from the centre, which was begun in the preceding reigns, became more disastrous in his. He was succeeded by his brother Al-Motassem, under whose reign the Seljuks first became body guards of the caliphs, whose empire they were in time to usurp.

ALMANAC (probably from the Arabic *al-manah*, the reckoning), a publication of the calendar, generally containing chronological records of religious festivals and memorable events, and astronomical data, as well as miscellaneous information. Tables representing almanacs were first used by the Arabs mainly as astronomical guides, and from them became known among the Alexandrian Greeks and in Europe. Manuscripts of some of those of the middle ages are preserved in various English and continental libraries. An almanac for 1836 was printed recently from a manuscript prepared in 1300 by Petrus of Dacia, containing chaotic astronomical, chronological, and medical data. The British museum and Corpus Christi college, Cambridge, preserve manuscript almanacs of the 14th century. The earliest printed almanac is believed to have been that of the German astronomer Purbach (Vienna, 1457). His pupil Regiomontanus published toward the end of the 15th century, under the auspices of the Hungarian king Matthias Corvinus, several numbers of a *Kalendarium Novum*, in German and Latin. "The Kalendar of the Shyppers," or "Shepherds' Calendar," an English translation of a French work, was published in Paris in 1497. Every month is introduced with a fragment of doggerel verses. The following is a specimen of its contents:

"Saturne is hiest and coldest, being full old,
And Mars with his bluddy swerde ever ready to kyl.
Sol and Luna is half good and half ill."

New editions of this almanac were published in the early part of the 16th century. The chief attractions of these and subsequent annual publications were prognostications of the weather and fortune-telling, and they became highly popular. Paynter's burlesque, "Four Great Syers" (about 1560), was followed in 1609 by Thomas Dekker's "Raven's Almanack," and in 1618 by Laurence Lisle's "Owle's Almanack." "Poor Robin's Almanack," the most famous of them all, was begun in 1663. Under James I. almanacs were monopolized by the universities and the stationers' company, astrology and superstition being their principal ingredients. Francis Moore's *Vox Stellarum* led the way in ad-

vertising quack medicines. "Poor Robin's Almanac" flourished until the monopoly of the stationers' company was broken up in 1775. An attempt for its renewal, made by Lord North in parliament, was baffled by Erskine's argument against it (1779), but the company nevertheless endeavored to retain the monopoly by buying up rival publications. "The Ladies' Diary," established in 1794, was of a better kind; but it was not until after the issue of the "British Almanac" (1828) that the stationers' company purged their "New Englishman's Almanac" of obnoxious matter. — In France, Rabelais made an ineffectual attempt to destroy the popular faith in the astrological predictions of almanacs. Nostradamus (1550-66) made prophecies popular to such an extent that political predictions in almanacs were prohibited by the French authorities on several occasions. Matthieu Laensbergh, a citizen of Liège of the 17th century, was the founder of the *Almanach liégeois*, printed under the name of Lansbert in 1625, and since 1647 under that of Laensbergh. It contained information about the planets, absurd medical prescriptions, and notices of religious holidays and historical events, and attained great popularity by predictions of weather and occurrences. An occasional hit, as for instance that of the predicted downfall of Mme. du Barry in consequence of the death of Louis XV., confirmed the credulous in their confidence in the almanac. At first it was also made convenient to the illiterate by the adoption of signs indicative of dates in place of letters. In 1823 the Netherlands authorities used repressive measures against the almanac on account of the objectionable political allusions, and its circulation was more seriously checked in 1852 by the French government. Since the year 1625 a calendar for shepherds (*Calendrier des bergers*) has been included in each annual almanac. Various spurious *Almanachs liégeois* are published in France, as for instance the *Triple véritable almanach de Liège*. Matthieu Laensbergh, the original founder, is still so popular in Belgium and France that from 1824 to 1829 a daily journal of Liège bore his name as a title, and he figures as the hero in a recent French comedy. Though modern works have in a great measure superseded these almanacs, the peasantry all over Europe still retain a great partiality for them. The *Almanach impérial* (since 1871 *national*) and *Almanach de France*, and the *Annuaire-Almanach du commerce* (published by Didot Jan. 1, 1872), are the leading French almanacs. Many almanacs are at the present day published in France under the title of *Annuaire*, or *Annuaire-Almanachs*. On the other hand, literary annuals and albums are published in France, Germany, and other countries under the title of almanacs, as for instance the German *Musenalmnach*, and the French *Almanach des muses*. Germany originated these annual collections about 1815, and they circu-

late there more extensively than the ordinary almanacs do in other European countries. A little Breton Almanac for 1872, *Almanach Breiz-Izel*, prepared by some of the best Celtic scholars in France, contains, besides agricultural, veterinary, philological, political, and historical lore, some popular tales, proverbs, patriotic poems, &c. The *Almanach de Gotha* is published both in French and German by Justus Perthes, at Gotha, Germany, and is (1873) in its 110th year. It is a high authority on the genealogy of sovereign and princely families, and statistics and official information respecting the different countries of the world. — Nautical almanacs, containing astronomical information designed to aid in the determination of latitude and longitude at sea, &c., have been published in France since 1679, and in Germany since 1776, under the respective titles of *Annuaire* and *Jahrbücher* or *Annalen*, and in England since 1767. The "American Nautical Almanac" was founded by Admiral Charles Henry Davis, U. S. N., who was appointed its first superintendent in 1849. The first volume, for 1855, was published in 1853. — The first ordinary American almanac is believed to have been issued from the press of William Bradford in Philadelphia in 1687. Franklin's celebrated "Poor Richard's Almanac," first published by him in 1732, and continued about 25 years, became very popular in this country as well as in England and France, where its proverbial and wise utterances were reprinted and translated. The "American Almanac and Repository of Useful Knowledge" was published at Boston from 1828 to 1861. The "National Almanac," designed as a continuation of the above, was published at Philadelphia for 1863 and 1864 only. There are now upward of 100 almanacs published in the United States, a number of them being illustrated, relating to almost all imaginable subjects of desirable information for all classes and occupations, and also including comic almanacs as well as versions in foreign languages, chiefly in German.

AL-MANSOUR, Abu Jaffar Abdallah, the second Abbasside caliph, born about 712, died Oct. 18, 775. He succeeded his brother Abul Abbas in 754. On his accession the sovereignty was claimed by Abdallah, his uncle. Abdallah, however, was completely defeated by Al-Mansour's lieutenant, Abu Moslem, who was soon after put to death for declining to serve as governor of Egypt. Nor was this the only instance of Al-Mansour's cruelty. In 758 Cufa, then the residence of the caliphs, was the scene of a riot got up by the Ravendites, a sect who believed in metempsychosis. This so displeased Al-Mansour that he founded Bagdad, to which city the seat of government was removed. His reign was again disturbed by a revolt of the descendants of Ali ben Abu Taleb, which was suppressed. His arms were victorious in Asia Minor, Armenia, and further east. Spain, however, was lost to the caliphate of Bagdad during

his reign. He was the first of the caliphs who introduced the taste for literature. In his reign many of the best Greek works were translated into Arabic.

ALMARIC or **Amalric** of **Bène**, or **Amaury** of **Chartres**, a French theologian and philosopher, born at Bène near Chartres, died about 1209. He was one of the most celebrated teachers of dialectics and the arts in the university of Paris, and devoted himself especially to the study of Aristotle, from whose writings he drew the germ of his own philosophical system. He taught that God was an immaterial substance, without form or figure, but with perpetual and necessary movement. All beings were derived from this primitive substance and would finally be absorbed in it. There were three epochs in the religious history of the world; the Mosaic law marked the epoch of God the Father; the gospel period was the epoch of God the Son, in which every man was a member of Jesus Christ, whose body was in everything as well as in the eucharist; the epoch of God the Holy Ghost was then about to begin, in which the sacraments were to cease and men to be saved by the interior infusion of the Spirit without the need of any external act. The work entitled *Physion* (now lost), in which Almaric explained this theory, was condemned by Innocent III., and the author was obliged to recant in 1204. His disciples exaggerated his errors, teaching that God the Father was incarnate in Abraham. They denounced the pope as Antichrist, and are accused of gross immorality. One of them, a goldsmith named Guillaume, announced himself as one of the seven personages in whom the Holy Ghost was to become incarnate, and pretended to the gift of prophecy. A synod held at Paris in 1209 sentenced Guillaume and nine others to the flames, and the corpse of Almaric was exhumed and burnt with his books.

ALMEH (properly *alimeh*, pl. *avalim*), an Arabic name given to the better class of public singers and dancers in Egypt, and sometimes erroneously applied also to the lower prostitutes and dancers, the ghawazi. The almehs form a separate social class, live together in companies, and often earn very large sums by their songs, dances, and improvisations, which are almost always of a lascivious character. Their services are generally called into requisition at banquets, marriages, and other festivals.—The ghawazi are a much lower class, including both male and female dancers, who travel from place to place, and exhibit in the public streets their dances, which, like those of the almehs, consist of lascivious movements of the body. The female ghawazi are prostitutes of the lowest class; yet a respectable Arab may without disgrace marry one of them who has abandoned her profession. Though the two classes are alike in the licentiousness of their lives and occupations, a sharp distinction exists between the almehs and the ghawazi, the former pandering to the higher orders of society, while

the latter (considered by many actually a distinct race of gypsies) address themselves to the populace.

ALMEIDA, a strongly fortified town of Portugal, in the province of Beira, near the Spanish frontier, 20 m. W. of Ciudad Rodrigo, on the river Coa; pop. about 8,000. One of the foremost strongholds of the kingdom, it was taken by the Spaniards in 1762, and by the French in 1810. When in 1811 Wellington compelled the retreat of the French from Portugal, the latter destroyed a large part of the fortifications, but these were soon restored by the British. In 1844 the insurrectionists, under Bomfim, held Almeida a few weeks against the troops of the queen.

ALMEIDA, **Francisco de**, the first Portuguese viceroy of India, born about the middle of the 15th century, died March 1, 1510. He distinguished himself in the peninsular wars with the Moors, and on his appointment to the government of the newly discovered Indian provinces, in 1505, was attended by a large number of volunteers. He extended the Portuguese power, but was unfortunate in an expedition against Calicut, losing his son Lorenzo and a part of his fleet. At this juncture Albuquerque came out to India, but Almeida refused to recognize him, and cast him into prison until he had avenged the death of his son, ravaged the coast, and destroyed a fleet of the sultan of Egypt, who was the ally of the king of Calicut. He then laid down his government, and sailed for home, but was killed by the natives at Saldanha bay, near the Cape of Good Hope.

ALMERÍA. **I.** A S. E. province of Spain, in Andalusia, on the Mediterranean; area, 3,299 sq. m.; pop. in 1867 (estimated), 352,946. The greater part of the province is broken by mountains and ravines, with small valleys and plateaux, nearly denuded of wood and subject to great extremes of drought and flood. There are very few roads and no public improvements. But it is one of the richest provinces of Spain in mines of silver, lead, copper, coal, salt, &c., which are worked in the most primitive manner, mining being the chief industry. There is little agriculture, but some grain and silk are produced, and cotton is raised to some extent along the coast, its cultivation having been introduced by Mr. Kirkpatrick, U. S. consul at Málaga, many years ago. The principal towns, besides the capital, are Vera, Purchena, Sorbas, and Berja. **II.** A city and the capital of the preceding province, situated on the Mediterranean, 104 m. E. of Málaga; pop. about 30,000. It was one of the most important commercial towns of Granada in the time of the Moorish kings, is still surrounded by the old Moorish walls, and has in general an African aspect. It was formerly the principal port of the coast, and at one time a notorious seat of pirates. The principal building is a magnificent cathedral.

ALMODOVAR, **Ildefonso Díaz de Ribera**, count of, a Spanish statesman, born about 1777, died in

January, 1846. On the fall of the constitution in 1823 he retired into France, whence he returned on the invitation of the regent Christina, was chosen president of the popular branch of the cortes, and in 1835 was appointed captain general of Valencia, where he ruled with great severity. Under Mendizabal he was successively minister of war and minister of foreign affairs, and the latter position he held also under Espartero in 1842-'3. In 1837 he was appointed senator.

ALMOHADES, a Moslem dynasty of northern Africa and Spain, which reigned in the latter half of the 12th century and in the earlier half of the 13th. The term is an abbreviation of Al-Mowahedun, which means the Unitarians. The origin of their power is traced to a certain Mohammed, or, with his full name, Abu Abdillah Mohammed ben Yumert, who travelled to Córdoba for education, and thence to Cairo and Bagdad to complete his studies. On his return from the east, Mohammed became conspicuous by the austerity of his life and the boldness of his preaching. He was made tutor of Abd-el-Mumen, a youth of high birth, whose mind he filled with a belief that he was reserved to inaugurate a purified Moslem creed. At Morocco he took up his abode in a burial ground, where he preached to the people the coming of the great Mahdi (director), who was to establish the reign of universal justice and peace upon the earth. One day as he was thus preaching, Abd-el-Mumen remarked, "You are yourself the great Mahdi," and immediately swore allegiance to him, in which he was followed by 50, and soon after by 70 others. They retreated to the mountains, preaching the unity of God, and soon their number was swelled to 20,000; and a victory over the king's brother established the influence of the Almohades. The war was kept up against them with varying success, but about 1130 they marched against Morocco, and obtained a complete victory. The Mahdi now summoned his followers, and, announcing his approaching departure, laid down his power, and was said to have been translated. Abd-el-Mumen was then elected sovereign. He overran Oran and Fez, and about 1147 reduced Morocco, the last refuge of the Almoravides, to extremities. After a desperate defence, the city was taken, and Abd-el-Mumen massacred the inhabitants and razed the town. In Spain the Almohades were equally successful. The Almoravides were defeated at every point. Abd-el-Mumen proclaimed a holy war, but died in the midst of his preparations, in 1163. His son Yusuf succeeded, at the age of about 24, and reigned until about 1184, when he died, while besieging Santarem in Portugal.—Yacub ibn Yusuf or Al-Mansour, his successor, carried on the war against the Christians, and in 1195 defeated Alfonso VIII. of Castile at Alarcos. He died in Africa in 1199. Mohammed Abu-Abdallah, his son, succeeded him. He levied a vast army against the Christians. Pope Innocent III.

having authorized a crusade, the clergy exerted themselves to repel the invasion; and on June 12, 1212, the battle of Navas de Tolosa was fought, in which Mohammed barely escaped with life, leaving, it is said, 170,000 dead on the field. He returned to Morocco, and resigning his crown to his son Yusuf Abu-Yacub, who was only 11 years old, died in 1213. With the latter prince, who died childless in 1223, the direct Almohade line terminated. Al-Adel and Al-Mamoun, both nearly related to Abu-Yacub, held for a time the empire of the Almohades, but it was soon torn asunder by internal divisions, and shortly after the middle of the 13th century disappeared.

ALMON, John, an English political writer, born in Liverpool in 1738, died Dec. 12, 1805. In 1759 he established himself as a bookseller in London. On the death of George II. he published a review of his reign, after which he published a "Review of the Administration of Mr. Pitt," besides "Anecdotes of Lord Chatham" (3 vols. 8vo), "Biographical Anecdotes of Eminent Persons" (3 vols.), and an edition of "Junius" (2 vols.), in which he attempted to prove that Hugh Boyd was Junius. He put his pen and press at the disposal of John Wilkes, and published a pamphlet on "Jurymen and Libellers," for which he was tried, but acquitted. He was also arraigned for selling copies of Junius's letter to the king, compelled to pay a fine, and to find bail to keep the peace for two years. He was the publisher of Wilkes's "North Briton," and wrote his life. In 1774 he established the "Parliamentary Register." He also compiled "The Remembrancer, or Impartial Repository of Public Events from 1775 to 1784" (17 vols. 8vo, and a prior volume relating to American affairs). In his latter years he became proprietor and editor of the "General Advertiser."

ALMOND (*amygdalus*), a genus of plants, the type of the sub-order *amygdalee*, comprehending the almond, plum, peach, cherry, nectarine, and a few unimportant bushes of a somewhat

Almond—Fruit, Flower, Leaves, and Nut.

gay appearance. The common almond (*A. communis*) is a native of Barbary, but has long been cultivated in the south of Europe and the temperate parts of Asia. The fruit is produced in very large quantities, and exported into northern countries. It is also pressed for oil, and used for various domestic purposes. There are numerous varieties of this species, but the two chief kinds are the bitter almond and the sweet almond. The sweet almond affords a favorite article for dessert, but it contains little nourishment, and, of all nuts, is one of the most difficult of digestion. The highly prized Jordan almonds are brought from Málaga. The tree has been cultivated in England for about three centuries, for the sake of its beautiful foliage, as the fruit will not ripen without a greater degree of heat than is found in that climate. The bitter almond contains less fixed oil than the sweet almond. It has a strong narcotic power, derived from the presence of hydrocyanic (prussic) acid, and is said to act as a poison on dogs and some other of the smaller animals. The distilled water of the bitter almond is highly injurious to the human species, and when taken in a large dose produces almost instant death. The leaves of all the varieties of *amygdaleæ* contain hydrocyanic acid, and are often dangerous, while the fruit may be used with entire impunity.

ALMONDE, Philippus van, a Dutch vice admiral, born at Briel in 1646, died near Leyden, Jan. 6, 1711. He served under Admiral Ruyter in the memorable sea fights of July, 1666; and after Ruyter's death, at Syracuse, Sicily, in 1676, the duty of taking the command of the Dutch fleet on its way home from the Mediterranean devolved upon him. He covered himself with glory at the battle of La Hogue in 1692, and assisted Cornelius van Tromp in reducing the naval power of Sweden.

ALMONER (anciently written *amner*), an officer appointed to distribute alms to the needy, generally an ecclesiastic. Such officers were from very early times in Europe attached to the households of sovereigns, nobles, and prelates, to monastic, educational, and charitable institutions, &c. In England there was a lord high almoner before the time of Edward I., and in modern times the title has been held by the archbishop of York. There is also a hereditary grand almoner in the person of the marquis of Exeter; and there is an almoner in Westminster. In France the *grand aumônier* was the chief ecclesiastic of the king's household, generally of high birth, and had several subordinates with great power and peculiar privileges. Since 1792 the office has been several times abolished and restored; it existed under Napoleon I. (Cardinal Fesch) and III. There are also almoners of the army and navy, &c. In the church, deacons have sometimes been called almoners (*elemosynarii*).

ALMONTE, Juan Nepomuceno, a Mexican general and diplomatist, born in Valladolid in 1804, died in Paris, March 22, 1869. He was of

partly Indian origin and the reputed son of Morelos. He held diplomatic posts at various times in Washington, London, Lima, and Paris. With Santa Anna, on whose staff he was then serving, he was captured by Gen. Houston at the battle of San Jacinto in 1836. Released after six months, he became minister of war under Bustamante. During the war with the United States he fought under Santa Anna, with whom he never ceased to hold friendly relations. He was ambassador to Paris in 1857-'60, and was one of the principal instigators of the French invasion of Mexico and the election of Maximilian. With the assistance of the imperial forces, he was appointed dictator of Mexico in 1862; but all parties distrusted him, and the French themselves removed him in September of the same year. In June, 1863, he was president of a junta styled the regency of the Mexican empire. In 1864 Maximilian conferred upon him the titles of regent and grand marshal, and in 1866 sent him as ambassador to Paris, where he spent the rest of his life.

ALMORA, a town of N. India, capital of the British district of Kumaon, Northwestern Provinces, situated among the Himalayas, 5,337 feet above the sea level, 90 m. N. by E. of Bareilly. It is built along a mountain ridge, in the midst of a barren and desolate region, and approached by a single long, zigzag road. It was captured by the Gorkhas in 1790, and held till 1815, when the town was attacked and stormed on the 25th of April by the British forces under Col. Nicholls, after which the district was annexed to the British territory.

ALMORAVIDES, a Moslem dynasty in N. Africa and Spain, which owes its origin to Abdallah ibn Yasin, who preached Islam among the Arabian tribes of northern Morocco, became the chieftain of the Al-Murabithin (the devoted, hence the word Marabout), and died in battle about A. D. 1058. Abubekr ibn Omar succeeded him, but during his absence on a warlike expedition, his lieutenant, Yusuf ibn Tashfyn, seized the supreme power. Abubekr, on his return, finding his rival too strong, resigned the crown, and Yusuf acknowledged his forbearance by magnificent presents, which he repeated annually during Abubekr's life. Yusuf now founded the city and empire of Morocco. Invited to Spain by the Moorish prince of Seville to aid him against the Christians, he sent an embassy to Alfonso of Castile announcing his arrival in the peninsula, and summoning that monarch to an unconditional surrender, and to embrace Mohammedanism. A desperate battle was fought in the plains of Zalaca in 1086, in which the Christians were worsted. Yusuf, however, retired, but the following year returned, conquered the Moorish kings in detail, and, having proclaimed his son as his successor, retired to Morocco, where he died in 1106. About 40 years later the dynasty of the Almoravides was overthrown by the Almohades.

ALMQUIST, Karl Jonas Ludvig, a Swedish author, born in 1793, died in Bremen, Oct. 26,

1866. He studied theology, and was for some time a teacher. Besides miscellaneous works, he published novels and poetry, including *Törnrosens Bok* ("Book of the Rose"). Implicated in a case of poisoning in 1851, he fled to the United States, but went to Bremen in 1865. His works are very popular in Germany, where most of them have been translated.

ALMY, William, an American philanthropist, born Feb. 17, 1761, died Feb. 5, 1836. He belonged to the society of Friends, and was a public teacher. Having made a fortune in partnership with his brother-in-law, Obadiah Brown, in manufacturing cotton goods, he devoted a large share of his wealth to charitable works, especially in Providence, R. I., where he lived. He endowed the New England yearly

meeting boarding school at Providence, and paid for the education of 80 of its pupils.

ALWICK, the county town of Northumberland, England, on the river Alne, 30 m. N. of Newcastle; pop. about 8,000. It is well built, chiefly of stone, with broad, well paved streets, lighted with gas. It has a fine town hall, and a large square where weekly markets are held. The ancient castle of the same name, N. W. of the town, the residence of the duke of Northumberland, covers five acres of ground, and was restored in 1830 at an outlay of £200,000. It is built of freestone, in the Gothic style, and is one of the finest old baronial residences in England. Alnwick castle formed one of the strongest bulwarks against the incursions of the Scots in ancient times, and was re-

Alnwick Castle.

peatedly besieged by them. Near its walls Malcolm III. of Scotland was slain in 1093, and his army routed; and in 1174 William the Lion was defeated here at the head of a large army, and taken captive.

ALOE, a genus of succulent plants belonging to the natural order *Liliaceae* and tribe *Asphodelae*, with long, fleshy, narrow, toothed leaves, growing in tropical countries. It has been divided into a variety of species, consisting of trees, shrubs, and evergreen herbaceous plants, which differ in height from a few inches to upward of 30 feet, and no less widely in the character of their leaves and flowers. A large proportion of these different species have no medicinal properties, but are seen as objects of curiosity, in collections of succulent plants; while a few species are highly valued for the juice of their leaves, which forms the aloes of commerce. (See **ALOES**.)

ALOE, American. See **AGAVE**.

ALOES, the inspissated juice of the leaves of different species of aloe. Several varieties are known in commerce, some much superior in quality to others. Cape aloes, obtained from the *aloe spicata*, growing at the Cape of Good Hope, occurs in masses of a shining dark olive-green color, of a vitreous fracture, and translucent at the edges; the powder is of a greenish yellow color, with a very disagreeable odor and intensely bitter taste. Barbadoes aloes is prepared in the West Indies, and is the product chiefly of the *A. vulgaris*. The color is a dark brown, not shining, and the odor is unpleasant. Socotrine aloes, from the *A. Socotrina*, occurs in pieces of a yellowish brown color, less shining than the Cape aloes; the fracture is conchoidal, the odor aromatic, and the taste very bitter. This is much the most valuable variety, and the name is applied to parcels of aloes of good quality coming from other sources than the island of Socotra.

Hepatic aloes, known in India as Bombay aloes, has a dark liver color, and is probably an inferior kind of drug, manufactured from the drugs of other sorts.—Aloes contains a neutral bitter principle called aloine, which acts as a cathartic in the dose of from one half to one or two grains, and insoluble matter called apotheme. It yields its virtues to water and alcohol, and is often administered, in its natural form or in combination with other substances, in pills. It is an irritant purgative, slow in operation, and acting chiefly on the lower bowel and the rectum. A peculiarity of its action is that an increase of the quantity administered, beyond the medium dose, is not attended with a corresponding increase of effect. When used for a long time, the dose may be rather diminished than increased. It is rarely used alone, but is combined with soap, rhubarb, colocynth, and iron in substance and in tincture. It forms an ingredient of a great number of empirical preparations. From 2 to 5 grains form a laxative dose; from 5 to 10 grains, a strong purgative. It is supposed to produce or irritate piles. Its tendency is to produce congestion of other pelvic organs, and it is therefore sometimes used as an emmenagogue.—The processes of preparing the drug are various. Sometimes the leaves are cut off at the stem, then cut in pieces, and the juice drained off in iron vessels. It is then suffered to stand for 48 hours, during which time the drugs are deposited, and the remaining portion is poured off into broad flat vessels, and becomes inspissated. In other places, the leaves are pulled, and after being cut in pieces, the juice is extracted by pressure.—The aloes or lign aloes (*i. e.*, wood aloes, Lat. *lignum*) mentioned in the Bible as a perfume was an entirely different substance. It was probably the product of the *aquilaria agallochum* of tropical Asia, which yields the highly aromatic aloe wood or eagle wood of commerce. There are many other species, the wood of which, like that of the preceding, is rendered more or less resinous and odoriferous by decay, with a bitter quality which gives it the name of aloes.

ALOIDE, in classical mythology, the gigantic sons of Neptune by the wife of Aloëus. Their names were Otus and Ephialtes. At the age of 9 their bodies measured 9 cubits in breadth and 27 in height, and they alarmed the gods by waging war on Olympus and piling Pelion upon Ossa. They put Mars in chains and kept him so 13 months. Before their beards began to grow Apollo destroyed them.

ALOMPRA, the founder of the reigning dynasty of Burmah, born about 1710, died May 15, 1760. He was originally chief of a small village. The king of Burmah having been captured and the country conquered by the Peguans, Alompra in 1753 headed an insurrection which, after a series of brilliant victories on his part with inferior means, ended in 1757 with the conquest of Pegu and the establishment of his power over both countries. His reign was

short, but was distinguished by great improvements in the laws and administration of government. He founded the city and port of Rangoon.

ALOST, or **Aelst**, a town of Belgium, province of East Flanders, about half way between Brussels and Ghent; pop. in 1866, 18,978. The Dender, an affluent of the Scheldt, which has been made into a canal for the accommodation of trade, passes through the town. It has considerable trade and manufactures, and was formerly the capital of Austrian Flanders. Captured by Turenne in 1667, the town was for a time in the hands of Louis XIV. It is well built and clean. In the church of St. Martin is a picture by Rubens representing "The Plague of Alost."

ALPACA, a species of the genus *Lama* of Fr. Cuvier (properly *Llama*), and *auchenia* of Illiger, which with the genus *camelus* constitutes the family of *camelidae*, of the order of *bisulca ruminantia*. The alpaca is found in the mountainous regions of Peru, and subsists

on the coarse and scanty forage which grows on the sterile soil of that quarter. The upper part and the sides of the body of this animal are covered with light chestnut-brown wool, which hangs down in slightly curled meshes nearly a foot in length, and is very soft and elastic, almost as fine as that of the Cashmere goat; the face up to the posterior margin of the jaws, and also the legs, have short, smooth hair; from the forehead a stiff silky hair falls down upon the face. The shearing of the wool takes place at irregular times annually or biennially. From 10 to 12 lbs. are obtained from one animal.

ALP ARSLAN (valiant lion), sultan of the Seljukian Turks, born in Turkistan about 1028, assassinated in 1072. He was descended from Seljuk, succeeded his uncle Togrul in 1063, and was also appointed by the caliph as emir-ol-morra or commander-in-chief. He conquered Armenia in 1065 and Georgia in 1068, and though repeatedly repulsed by the troops of the Byzantine empress Eudocia, he eventually carried his victorious arms from Antioch to the Black sea. After the capture and death of Eudocia's husband and general, the emperor Romanus Diogenes (1071), he planned an expedition against Turkistan, the cradle of his dynasty, and

crossed the Oxus with an immense army; but he was stabbed to death by the governor of the first fortress he captured, whom he had ordered to be executed in revenge for his obstinate defence. Alp Arslan's virtues as a ruler are no less extolled than his courage as a warrior.

ALPENA, a county of E. N. E. Michigan, on Lake Huron and Thunder bay, drained by Thunder Bay river; area, 700 sq. m.; pop. in 1870, 2,756. In 1870 there were only 319 acres of improved land. Capital, Alpena.

ALPES, Basses and Hautes. See *BASSES-ALPES*, and *HAUTES-ALPES*.
